*Seat of lesion.*—In no less than thirty-three out of the fifty cases the only lesion that could be definitely made out was mitral regurgitation. This confirms what is, I think, the general experience, that this is much the commonest form of valvular defect. We must, however, bear in mind the well-known fact that it is common at post-mortem examinations to find lesions of the aortic valves which had escaped recognition during life. If we looked at clinical evidence only we should probably overestimate the relative frequency of mitral lesions. My cases do not happen to include a single instance of pure mitral obstruction, and I must express my opinion that this is a somewhat rare form of valvular defect. It is commoner in children than in adults and in the female than in the male sex. Only one case of combined mitral obstruction and regurgitation is included in my cases, although this has been in my experience a commoner defect than pure mitral obstruction. In 13 out of the 50 cases both aortic and mitral valves were affected, the most usual condition being the association of aortic regurgitation with mitral regurgitation. I am disposed to think that in most of the cases of combined aortic and mitral regurgitation the aortic lesion was primary and the mitral secondary. In only 2 of my cases was there pure aortic regurgitation without (sooner or later) mitral involvement, and in only 1 was there coexisting aortic obstruction and regurgitation without mitral defect. I have no records in my present series of any case of pure aortic obstruction; and I believe this, like the corresponding lesion of the mitral valve, to be a somewhat rare affection. My cases would then, so far as they go, seem to warrant the following conclusions regarding the relative frequency of the different valvular lesions—(1) That pure mitral regurgitation is much the commonest of all; (2) that next in order follow aortic lesions combined with mitral regurgitation; (3) that pure obstruction, either at the mitral or aortic orifice (at least sufficient to cause symptoms and afford adequate grounds for diagnosis) is a somewhat rare condition.

*Age.*—I find that of the 50 cases 27 had attained the age of thirty or upwards, while 23 were under that limit. On inquiring into the influence of age upon the relative frequency of the various lesions I find some interesting results. Thus the average age of 33 patients with pure mitral disease was found to be twenty-nine, while the average age of 14 patients in whom the aortic valves were affected either with or without mitral disease was found to be forty-one. This is a decided contrast, and illustrates the well-known rule that mitral disease falls rather on the earlier years of life and that aortic lesions become more frequent with advancing age. This law is explained by the fact that mitral lesions are usually the result of endocarditis, while aortic lesions are often the consequence of atheroma or other degenerative change in the walls of the arteries.

*Sex.*—I find that 26 of my 50 cases were males and 24 females, which would seem to indicate that sex has little influence in predisposing to valvular lesion of the heart. This is in striking contrast to the facts regarding aneurysm, which, as is so well known, occurs with greatly preponderating frequency in the male sex.

*Etiology.*—My cases bring out strongly what is the most

familiar fact in connexion with the etiology of valvular lesions of the heart—viz., the great part played by rheumatism.

In 27 out of the 50 cases there was a clear rheumatic history. In 5 of the cases rheumatism was associated with scarlet fever. In 23 cases no history of rheumatism could be made out. I have sifted this series of cases as carefully as possible regarding the pathological conditions either antecedent to or associated with the valvular lesion with the following results. Two cases were probably congenital, and may therefore be dismissed. In 6 cases hard drinking was acknowledged. Syphilis was present in 4 cases. Chronic bronchitis was likewise present in 4 cases. Bright's disease was also found in 4 cases. In 2 cases remittent fever had existed, and in most of the remaining cases no trustworthy data were available. These figures would seem to indicate that (as is universally admitted) rheumatism is by far the most potent factor in the causation of valvular cardiac lesions, and that next follow (but at a great distance) drink, syphilis and renal disease. In a very large number of cases the important element of muscular strain was present, but I have found it impossible to separate this from the other conditions enumerated. As regards the rheumatic cases, my records seem to show that the heart often withstands the first attack of rheumatism, sometimes a second, but that it inevitably gives way when there is a series of such attacks. I have not been able to make out to my satisfaction the probable duration of the cardiac lesions before the cases came under observation. One case had apparently lasted ten years, another five years, but in most cases there were no adequate data for determining the point. As regards the results of treatment, 15 cases died and the remaining 35 improved. In 17 cases the improvement was noted as slight or fair, and in 18 cases as marked and decided. Of the 15 fatal cases 9 were cases of mitral regurgitation, 2 were cases of pure aortic regurgitation, and 3 were cases of combined aortic and mitral disease.

I now wish to invite the attention of the Ulster Medical Society to a few general problems of prognosis in the class of affections under consideration. First, what is the relative gravity of the four principal valvular lesions of the heart? We may answer, I think with confidence that pure aortic obstruction is the least serious, pure aortic regurgitation the most serious, and that affections of the mitral valve are intermediate. Opinions have differed much regarding the relative gravity of mitral obstruction and mitral regurgitation. On the whole I incline to the view of Drs. Bristowe, Wilks, Peacock and Sansom that the prognosis is somewhat more favourable in obstruction, as it has seemed to me that compensation is better maintained in this lesion than in regurgitation. I would point out, however, that, as the majority of the cases of mitral obstruction which come under observation are found either in children or women, whereas mitral regurgitation is common in both sexes and at all ages, the comparison is hardly a fair or an instructive one.

I pass on to consider a much more arduous problem. Given a case of, say, mitral regurgitation, can we determine with any approach to accuracy the probable duration of life? It is now quite certain that these cases may live for ten, twenty, thirty, or forty years, so that in fact their serious defect may not shorten life at all; or, on the other hand, they may hardly live so many weeks or days. It becomes a most interesting and vitally important question to determine how far we can draw the line between the two classes of cases. Perhaps I shall best solve the problem that I have propounded by giving the substance of the teaching of Sir Andrew Clark, Professor Gairdner, Dr. Clifford Allbutt and others who have defined for us with considerable precision the cases of mitral regurgitation which may be reasonably expected to survive for many years. Sir Andrew Clark enumerates the following conditions as enabling us to speak favourably of the prospects of life in such cases:—(a) General good health; (b) just habits of living; (c) no exceptional liability to rheumatic or catarrhal affections; (d) origin of the valvular lesion independent of degeneration; (e) existence of the valvular lesion without change for over three years; (f) sound ventricles of moderate frequency and general regularity in action; (g) sound arteries with a normal amount of blood and tension in the smaller vessels; (h) free course of blood through the cervical veins; (i) freedom from pulmonary, hepatic and renal congestion.

I need hardly point out that the cases of mitral regurgitation presenting all these conditions are very exceptional

<sup>1</sup> An introduction to a discussion on Chronic Valvular Disease of the Heart at the Ulster Medical Society. No. 3604.

indeed; but they do occur sometimes, and it is most important that we should be able to recognise them." One of the conditions—viz., that the lesion shall have existed without change for over three years—is obviously a point very difficult of determination; and impossible to establish on a first examination. Hence, it is only after we have had a case of this kind for some time under observation that we are justified in speaking hopefully of the prospect of life. There is one class of case that calls for care and discrimination as regards prognosis. I mean where we have some regurgitation through the mitral valve as the result of sudden dilatation of the left ventricle and independent of actual structural damage to the valve. Some years ago a gentleman consulted me under the following circumstances. He had enjoyed good health until a few days previously, and had never had rheumatism. A few days before his visit to me he had undergone severe and unusual physical strain and had been seized with sudden and severe dyspnoea, which continued up to the time of my examination. I found the heart acting violently, but there was no evidence of hypertrophy. Auscultation revealed a loud bellows murmur at the apex and heard over a wide area. There was no pulmonary congestion, dropsy, or other evidence of systemic engorgement, and the only symptom complained of was the dyspnoea. I formed the opinion that in all probability the case was one of acute dilatation of the left ventricle from overstrain, and that while the prognosis was not free from anxiety, the prospects of recovery were good. I accordingly spoke encouragingly; ordered complete rest and tonics. The case rapidly improved, and in a short time all the troublesome symptoms had disappeared. I have not seen the patient for some time, but have lately heard that now, at the expiration of several years, he remains perfectly well. We must remember that all cases of acute dilatation of the left ventricle do not pursue this favourable course. Sometimes dropsy and the other signs of cardiac failure rapidly supervene and the patient dies, but the prognosis is essentially different from that of organic valvular disease. The particularly loud murmur present in this case leads me to remark that there is no greater error in dealing with cardiac disease than to regard a loud murmur as necessarily indicating a serious lesion. As a matter of fact the rule is rather the other way. In regurgitant mitral disease the loudest murmurs are produced by a small amount of blood being strongly forced through the valve by a vigorously contracting ventricle. The worst sign of all is where a loud murmur gradually becomes feebler and eventually disappears owing to failing contractile power of the ventricle. A murmur may, of course, also become feebler owing to increasing competence of the valve. The clinical signs will serve to differentiate the two cases.

There seems no doubt that occasionally, though rarely, organic valvular disease may entirely disappear. The best observers are agreed upon this point. There is no doubt whatever that the cardiac murmurs often present in chorea pretty frequently disappear, and everything seems to point to the conclusion that these murmurs are organic and not functional. The topic of prognosis in valvular affections naturally suggests the question whether any of the subjects of this affection may be fitly passed for life insurance at some increased premium. Most offices refuse positively to accept any applicant who has any form of cardiac disease; but this is not an absolutely universal rule and the point may arise with any of us. Sir Andrew Clark and Dr. Clifford Allbutt are both of opinion that certain cases in the class under consideration may be safely selected for insurance at some heavy increase of premium. The cases recommended for such a course are such as those previously described as affording grounds for a hopeful prognosis. Cases of mitral regurgitation, which have remained *in statu quo* for several years, where there is no change in the ventricle, no accentuation of the pulmonic second sound, no evidence of embarrassed circulation, and no subjective symptoms, are suggested as fair subjects for insurance at certain rates. Dr. Clifford Allbutt advises that such cases, if accepted, should be put upon the early payment system, so that all the premiums should be paid by the age of thirty or thirty-five. I confess I should hardly feel at liberty at present to recommend for insurance any applicant who presented the signs of organic valvular disease of the heart, though I have little doubt that there will, in the early future, be such an advance in precision of prognosis as to permit of this being done in a manner equitable alike to applicants and to the insurance companies.

## ON FREE FLUID IN THE ABDOMINAL CAVITY OF THE FEMALE.

By JAMES OLIVER, M.D., F.R.S. EDIN., F.L.S.

In the majority of cases the fluid which is found free in the abdominal cavity resembles the normal transudations of the body. Occasionally, however, it differs from dilute liquor sanguinis as it may be poured out by the rupturing of some cyst or abscess or the bursting of one or more blood-vessels. From the peritoneal sac of a well-fed animal, especially after the ingestion of a good meal, one is able to collect a quantity of serous fluid. Under ordinary circumstances, however, the arterial and venous pressures are so regulated that this liquid does not accumulate, but forthwith it finds its way again into the blood through the lymphatics. When therefore dropsy of the peritoneum occurs we may practically consider it as resulting in consequence of some derangement of a physiological phenomenon. The capillary system we know is the seat of the phenomena of nutrition, absorption and secretion, and it is to this system we must look for an explanation of the manner in which dropsy of the peritoneum takes place. If in a healthy animal we ligature the principal vein of a limb it does not follow that by thus interfering with the return of blood we shall produce œdema of this extremity. When, however, we cut the vaso-motor nerves the interstitial meshes of the area so disturbed are forthwith more or less markedly infiltrated by a serous exudation. In this case we destroy that tone of the vessels which is so essential for the maintenance of those physico-vital processes which are for ever going on, and by so doing we favour not only the transudation of serum, but interfere with the rate of absorption. Dropsy of the peritoneum very frequently depends upon inflammatory disease of the kidneys or upon organic disease of the lungs or heart. In this group of cases it is but a portion of a general dropsy, as the universal areolar tissue is similarly infiltrated. It is not my intention to deal at present with this form of ascites, but with that which, generally speaking, is not attended with anasarca elsewhere. The following are a few cases selected from a considerable number belonging to this category which have come under my own observation.

**CASE 1.**—*Free fluid in the abdominal cavity in association with fibroid induration of the stomach and general fibroid thickening of the peritoneum.*—A. L.—, aged thirty-five and married twelve years, had one child ten years ago. Menstruation, established at the age of twelve, has usually lasted five days. She was last unwell fourteen days before coming under my care on Oct. 20th, 1888. Since Oct. 1887—i.e., for twelve months—the patient has complained more or less constantly of a "grumbling pain" in the abdomen. This pain has never been severe. During this same period she has also complained of sickness. At first she vomited only occasionally, but latterly she has been sick at least once every day. Sometimes she has experienced severe stabbing pain in the region of the stomach, especially after the ingestion of food. About July, 1888, she remarked that her abdomen was increasing in size, and since then it has gradually become more and more prominent. There is nothing to note about the bladder except that the patient states she has always had to micturate frequently. During the last three weeks the bowels have been opened two or three times a day. Throughout this illness the menstrual discharge has recurred regularly every four weeks, and there has been no variation as to amount. The patient thinks she has gradually been losing flesh during the last two years.

**Physical signs.**—The abdomen is prominent, but not tense; it is tender all over to the touch, and dull to percussion to midway between the pubes and umbilicus; this dullness extends into the right flank, whilst the left is resonant; the dullness on the right side is not affected by altering the position of the patient; fluctuation is readily elicited. The vaginal examination revealed nothing of note in the pelvis.

From the date on which this patient came under my observation—viz., Oct. 20th, 1888—until April 3rd, 1889, when she died, the stomach emptied itself of its contents once or oftener every day. During this period she was tapped twice. The first tapping was performed on Dec. 28th, when a gallon and a half of straw-coloured serum was drawn off; at the second tapping, on Jan. 5th, one gallon only was removed. The temperature throughout was practically normal.

**Necropsy.**—On opening the abdomen a large amount of straw-coloured serum escaped, and with it flakes of lymph. The large bowel in its whole extent was enormously distended, whilst the small intestines were firmly matted together. The omentum, which was spread out like an apron, was firmly adherent to the pubes. The serous covering of the liver was much thickened. The stomach was so contracted that its capacity was only equal to about three fluid ounces. Its wall, which was uniformly thickened, measured five-eighths of an inch in thickness. The pyloric orifice was so constricted that it must have been difficult for even fluid to pass through it. The pelvic peritoneum was so much thickened that it was impossible to recognise the ovaries as such. In both chests the parietal and visceral pleura were firmly and universally adherent. The microscopic examination of sections of the stomach revealed only a very great excess of fibrous tissue.

This case is one of very great interest. The serous membrane of the chest as well as of the abdomen was so universally the seat of change, and the stomach itself was likewise so extensively invaded by fibrous tissue, that I am inclined to attribute these changes to some disturbance of the sympathetic nerve, and this disturbance was most probably of the nature of sclerosis. If in an animal we cut out certain ganglia of the sympathetic violent inflammation of the peritoneum and pleura is exceedingly apt to follow. Unfortunately the sympathetic was not examined in the above case, as the idea that the whole train of events might probably have been due to change in this system did not suggest itself to me until some days after the necropsy. On studying carefully the results obtained by experimenting upon the sympathetic I am firmly of opinion that had it been examined some very decided structural change would have been detected. This hypothesis is sustained, too, by the clinical facts. For twelve months prior to coming under my care she had complained more or less constantly of a "grumbling pain" in the abdomen, and occasionally of severe stabbing pain referred to the epigastric region. About the same time she noted a proneness to sickness. For three months she had observed that the stomach had been gradually increasing in size. To what, then, I ask, may the dropsy of the peritoneum be attributed? In consequence of the change in the stomach the patient was gradually being starved, and yet a fair quantity of serous fluid was passing out of the vessels into the abdominal cavity. When the peritoneum is opened in the case of animals which have been starved very little fluid is found in this sac; it is, in fact, dry. The change in the texture of the peritoneum would undoubtedly interfere with the process of absorption, for the lymphatic orifices and channels would be more or less completely closed and obliterated, and direct absorption would also be interfered with, for in order that this may proceed the fluid should be in as immediate contact with the capillary vessels as possible. The structural change in the peritoneum did not, however, interrupt the transudation of serum—in fact, the fluid passed out more abundantly than it ought to have done. Now, it is hardly likely that the increased exudation was due solely to the structural state of the peritoneum, although it may have been aided by the change, whereas it probably was due to some disturbance of the vaso-motor nerves.

**CASE 2. Dropsy of the peritoneum in association with malignant disease of the omentum.**—E. N., aged fifty-three, a widow, had one child twenty-eight years ago. She has never had any miscarriages, and she ceased menstruating seven years since. During the last twelve months the patient has remarked that her abdomen has been gradually increasing in size, and for four months she has complained more or less of pain all over the abdomen. There is no bladder or rectal trouble, neither has there been any swelling of the feet or legs.

**Physical signs.**—The abdomen is prominent but not tense. It is dull to percussion everywhere except in the epigastric area. The dullness in the left flank is not affected by the position of the patient, whereas the right flank becomes resonant as she lies on her left side. Fluctuation is readily elicited. On palpation there is no evidence of the existence of a new growth in the abdomen. The vaginal examination reveals nothing of note. An exploratory incision was advised and made. On opening the abdominal cavity a large quantity of deep amber-coloured fluid escaped. There were no flakes of lymph. The omentum was converted into a modulated malignant mass and here and there secondary nodules were observed in the peritoneum.

What is the cause of ascites in cases of this description?

Extensive degeneration of the peritoneum is said to be a cause of dropsy of the abdominal cavity. In the case which I have just recorded and in the majority of cases of malignant disease of the omentum effusion of serum takes place usually at a very early stage, and before the peritoneum has become extensively diseased. In the late stage, when the serous membrane is studded with malignant growth, œdema of the lower extremities is almost invariably noted. This anasarca of the limbs, it would appear, is to some extent the result of pressure, since one leg is usually markedly œdematous before the other. It is probably also determined by the general constitutional enfeeblement of the patient. In those cases in which the growth is malignant the serous exudation goes on steadily increasing and accumulating, whereas when the growth is of a benign character there is sometimes a lull; and patients often tell us that on one or two occasions the abdomen has diminished in size and has even, in fact, returned to its natural size. These diminutions are due to an actual decrease in the amount of the fluid and are not to be considered as resulting simply from an alteration in the state of the intestines. There is in reality a lessened transudation and an increased absorption of liquid. Transudation of serum takes place more profusely from the peritoneum covering a malignant than a simple growth, and the blood state induced by the presence of a malignant growth favours not only the exudation of serum, but hinders endosmosis.

**CASE 3. Fluid in the peritoneum in association with a deposition of tubercle in this membrane; recovery under treatment.**—On May 20th, 1891, Mr. Harley of Rainham, Essex, consulted me regarding E. L., aged eighteen, a single woman. The patient began menstruating at the age of thirteen, and the discharge had usually lasted three days. For five months prior to coming under my observation there had been a total suppression of the catamenial discharge. About the same time—i.e., five months ago—the patient remarked that the abdomen was large, and it has gradually become more and more prominent. During this same period she has occasionally complained of pain in the abdomen and back. Three months since there was œdema of the left foot and leg, but this passed away in a couple of weeks. She has not lost flesh, neither has she complained of bladder nor rectal trouble.

**Physical signs.**—The abdomen is prominent and tense. The percussion note is dull from the pubes to two inches above the umbilicus, and the area of dullness extends laterally on each side to a line drawn vertically from the anterior superior spine of the ilium. Both flanks are resonant. Fluctuation is readily elicited. On palpation a small nodule is detected on the left side, a little above the anterior superior spine of the ilium and midway between it and the linea alba. At the upper limit of dullness and on the left side is felt a more solid body, which appears to be intestines matted together. Vaginal examination: The uterus is low in the pelvis. The os looks downwards, and the body is felt anteriorly and on the right side, lying on the pelvic floor. Fluctuation is conveyed from the abdomen to Douglas's pouch. The bladder was emptied by the catheter, one ounce of urine being drawn off. The temperature was 100.6° F. Under treatment the abdominal swelling gradually disappeared, and on March 6th, 1892, Mr. Harley informed me that this patient was practically well. Since August she had menstruated regularly every month and lost as usual. "But," he added, "for three weeks now there has been a small amount of bloody discharge every day." I have seen cases similar in many respects to this one recover not only under general treatment, but also after the removal of the ascitic fluid by abdominal section. Sometimes the peritoneum has even been studded with what appeared to be miliary tubercle, and yet the fluid did not reaccumulate. A few of the cases, in fact, appeared to be perfectly well when seen twelve and eighteen months after the abdominal exploration.

What is the cause of the dropsy of the peritoneum in cases of this class? If the change in the serous membrane is the cause of the excessive transudation of fluid in these cases, and the deposition of tubercle in the lymphatics the probable cause of the interference with absorption, it is difficult to understand how the fluid disappears in some cases under treatment and does not reaccumulate in others after abdominal section. Under the latter circumstance it is not even necessary to drain the abdominal cavity after the completion of the operation. In some cases of tubercular peritonitis there is œdema of both lower extremities as well as dropsy of the abdominal cavity, and the amount of effusion is ap-

parently regulated by the general condition of the patient. I am therefore of opinion that the transudation in cases of this group is due to an alteration in the composition of the blood, and that the effusion takes place first and most markedly into the meshes of that tissue which is the seat of irritation. To some extent it is determined and regulated by a disturbance in the relationship of the arterial and venous pressures. In many cases of tubercle improvement in the state of the constitution does take place, and this may account for the disappearance occasionally of the fluid from the abdominal cavity under general treatment and for the non-accumulation after evacuation by abdominal section. In cases of malignant disease of the peritoneum we cannot hope for absorption or arrest of secretion, for the blood dyscrasia steadily progresses and the constitution of the patient is gradually undermined.

**CASE 4. Fluid in the peritoneum in association with papilloma of the ovaries, tubes and pelvic peritoneum generally; no evidence of cystic change; papilloma rather adenomatous than malignant in character.**—H—, aged thirty and married eleven years, has had two children, but no miscarriages. The last child was born nine years ago. Menstruation established at the age of fourteen; has usually lasted five days. The discharge recurs regularly every month, and is neither altered in amount nor character. She was last unwell fourteen days ago (Aug. 23rd, 1891). For three months the patient has remarked that the abdomen has gradually increased in size. At no time has she complained of pain.

**Physical signs.**—The abdomen is prominent but flaccid. The percussion note over the greater part of the anterior surface of the abdomen is resonant. Both flanks are dull. The right flank becomes resonant when patient turns on to her left side, whilst the note in the left flank is not altered by position. Vaginal examination: The uterus, which is fairly central (mesially) is pushed rather towards the pubes. It is surrounded by free fluid. On the right side is felt a small tender swelling, probably the ovary. On the left side is felt only some ill-defined thickening. For five months I kept this patient under observation, and during this time I failed to detect any evidence of material change in the abdominal state. Important changes, however, were noted in the pelvis; the small swelling which I had at first noted to the right of the uterus had gradually increased in size and become more irregular, and other nodules of varying size were also detected in the neighbourhood of this the first swelling. The thickening noted to the left of the uterus had not apparently altered. Abdominal exploration was now advised and was performed. On opening the abdomen a large quantity of deep-amber-coloured serum escaped. The omentum was occupied by what at first sight appeared to be a few flaccid cysts; on closer inspection, however, these swellings proved to be simply localised exudations of serum between the folds of the omentum. In the pelvis, and apparently springing from the right ovary, was found a papillomatous mass about the size of a turkey's egg. This mass, which was extremely friable and very vascular, was removed. On the left side a similar but more sessile mass was also found, but this could not be removed. The pelvic peritoneum was studded with small nodules of a similar character. The ovaries and tubes, as such, were not detected. The abdominal peritoneum was apparently unaffected.

In this case the disease was confined to the pelvic peritoneum; and I am of opinion that an increased transudation of serum took place from these highly vascular papillomatous growths, and that there being no compensatory increase in absorption, but possibly rather an interference with this process in consequence of the condition of the patient, the liquid accumulated and produced dropsy of the peritoneum.

**CASE 5. Fluid in the peritoneum in association with cystic and malignant disease of both ovaries and malignant disease of the omentum; necropsy.**—H. H—, aged forty-eight, a single woman, ceased menstruating twelve months ago. Four months ago—in July, 1891—the patient began to complain of general soreness in the abdomen and, at the same time, accidentally she detected a small lump in the lower abdomen on the right side. The abdominal discomfort was aggravated by any exertion. Since July the abdomen has gradually become more and more prominent, and she has lost flesh. Seven years ago the patient says she had an illness similar to the present one and that she then as now complained of soreness in the abdomen and also detected a swelling on the right side. The swelling, however, she alleges, disappeared after three or four months'

time, and she considered herself well till the occurrence of the present illness.

**Physical signs.**—The abdomen is so greatly distended that the skin is tense and glossy. The percussion note over the lower part of the abdomen from the pubes to the umbilicus is absolutely dull and this dullness extends towards both flanks. The left flank is dull whilst the extreme right is resonant. The upper limit of the dullness is somewhat concave in outline. Obscure fluctuation is detected over the area of dullness. Chest: Both chests below the level of the scapula are dull to percussion, and clear serum was drawn off from the right by an exploring syringe. Vagina: The vaginal roof is occupied by a hard swelling, which projects somewhat posteriorly. The cervix is pushed forwards and to the right. The body of the uterus appears to be embedded in a pelvic mass. On passing the catheter it strikes against a hard body.

There was no oedema of the legs until the patient had been under observation seven days. On Nov. 3rd, 1891 (about a month after the patient had been in hospital), I inserted a small trocar at a spot midway between the pubes and umbilicus, but I only drew off fifty-two ounces of a dark greenish fluid. The specific gravity of this fluid was 1020, it contained peptone and became solid on boiling, its reaction was alkaline. The withdrawal of this fluid afforded no relief, and the abdominal tension was unaltered by the tapping. On Nov. 27th she died.

**Necropsy.**—The pericardium and heart were normal. Both pleural cavities contained a quantity of fluid, that in the right was clear whilst that in the left was deeply blood stained. A few small white nodules of growth were observed in the lungs. These were situated immediately under the pleura and were flattened. A large quantity of ordinary ascitic fluid escaped on opening the abdominal cavity. The peritoneum, which was much thickened, was studded with malignant nodules of small size. The omentum was a malignant mass. The liver, spleen and kidneys were normal. The uterus contained several fibroid growths, two of which were calcareous. It was adherent to the bladder and to two large cysts. One cyst arose from the right horn of the uterus and reached the umbilical level. It passed in front of the uterus somewhat and occupied a central position. It did not invade the pelvis. It contained a greenish fluid, and it was evident that this was the cyst which I had tapped during life. It was unilocular, and at its base were found cancerous-looking nodules. Passing from the left side behind the uterus and filling the whole pelvis was another cyst, smaller, but also unilocular and exhibiting cancerous nodules at its base. This cyst had pushed the uterus towards the right wall of the pelvis.

The diagnosis in this case was extremely difficult, although the physical signs indicated the existence of some malignant change. The history tended to mislead. The patient affirmed that seven years previously she had suffered in a very similar manner, and that then a tumour was detected on the right side, but which soon afterwards disappeared. It is impossible to say what may have been the nature of this swelling, although it is more than probable that it was not an ovarian cyst. The fluid drawn from the right pleural cavity being ordinary serum did not help us in deciding the cause, whereas if the left chest had been explored and hæmorrhagic fluid had been drawn off, the presumption would have been strongly in favour of malignant changes. The fluid drawn from the abdominal cavity did not even allow of a more complete examination, but merely informed us that we had tapped a cystic accumulation. It was impossible to draw off the ascitic fluid, as the area of dullness was so limited and the distension of the abdomen so great.

**CASE 6. Fluid in the peritoneum in association with a multilocular ovarian cyst with no adhesions, but with evidences here and there of degenerate change in the cyst wall in consequence of a partial twist of the pedicle.**—M. M—, aged fifty-seven and married thirty-five years, has had nine children. The last child was born sixteen years ago. The catamenia ceased at the age of forty-nine. Eight months ago—about March, 1891—the patient noticed that on walking the womb dropped and that sometimes it even came outside altogether. About the same time she remarked that the abdomen was increasing in size and it has gradually become more and more prominent. There is no swelling of the legs.

**Physical signs.**—The abdomen is distended, but not tense. It appears to be more prominent a little to the left of the umbilicus. Over the front of the abdomen is an area of dullness, extending from the pubes to two inches and a half above the umbilicus and transversely from the left anterior

superior spine of the ilium to a line rising vertically from a spot a little external to the middle of the right Poupart ligament. The limit of dullness is not, however, sharply defined. Both flanks are resonant. Midway between the umbilicus and the ensiform cartilage is felt an irregular mass, some of the nodules of which, especially on the right side, appear to be cystic. Below the umbilicus, and more especially to the left of the middle line, the fingers on dipping sharply displace free fluid, and come upon a hard mass which appears to be continuous with the irregular mass already noted. The vaginal walls are very flaccid. The cervix uteri is located rather towards the right wall of the pelvis.

Having seen several cases very similar, I expressed the opinion that we had to deal with a multilocular ovarian cyst and free fluid in the peritoneum, and advised operation. The abdomen contained a large quantity of ascitic fluid. The tumour which was removed was a multilocular ovarian cyst of the right side. There were no adhesions. The pedicle was twisted, but not sufficiently to produce strangulation. Here and there the cyst wall presented patches in a state of fatty degeneration. The cyst contained no papillomatous or malignant growth. Since the operation in October there has been no evidence of reaccumulation of fluid in the peritoneum. It seldom happens that a large quantity of ascitic fluid is noted in association with a simple multilocular ovarian cyst with no adhesions. It is fairly frequently observed when papillomatous growths are detected in the interior of the cyst, and which have extended more or less completely through the entire thickness of the cyst wall. In cases of this latter description rupture of the cyst often takes place. When the papilloma reaches the peritoneal covering of the cyst the general peritoneum is exceedingly liable to become similarly affected; and in many cases of this character, after the successful removal of the tumour, the patient dies eventually with malignant disease of the peritoneum. I am unable to give a feasible explanation of the manner in which dropsy of the abdominal cavity takes place in association with fatty degeneration in the wall of an ovarian cyst; suffice it to say that they are correlated. I have also seen dropsy of the peritoneum in association with fibroid of the uterus, whose structure had undergone degenerative change at spots.

Gordon-square, W.C.

## FRACTURE OF BASE OF THE SKULL WITHOUT INJURY TO THE BRAIN.

BY R. D. MOTHERSOLE, M.S., M.D. LOND., F.R.C.S. ENG.

IN his instructive and interesting lecture recorded in THE LANCET of Aug. 20th Mr. Page remarks: "A fracture of the base is not in itself of much moment; its only importance lies in the fact that a basal fracture cannot well occur without grave concomitant injury to the brain." The comparative rarity with which this fracture occurs, apart from cerebral injury, leads me to think that a short account of two such cases may be of some interest. They came under my notice as senior house-surgeon to the Liverpool Northern Hospital in 1890.

The first case was reported by me in the *Guy's Hospital Gazette* for 1890, in order to emphasise the distinction between fractured base with and without brain injury. A robust man of about forty had a heavy cask roll on to his head as he lay on the ground. If he lost consciousness at all it was only for a few seconds. On admission to the hospital there was bleeding from both ears; that from the left soon ceased, but the right continued to bleed for twenty-four hours. From the position of cuts and bruising on the sides of his head it appeared to have been "nipped" in the bi-temporal diameter. In three days' time facial paralysis appeared on the left side. He declared all along that there was nothing much the matter with him, and was with difficulty persuaded to remain in hospital even for a week. In this case there seems certainly to have been a fracture through the left petrous portion, and the copious hæmorrhage from the right ear makes it probable that a transverse fissure extended right across the base of the skull.

The second case occurred a few weeks later. R. B—, a man of forty-seven, was admitted on Sept. 8th, 1890. While taking a barrel of whisky down a flight of steps, descending backwards and steadying the barrel with his knees, he slipped and fell forwards against the steps, the barrel rolling over his

head. He did not lose consciousness. On admission into the hospital he had some cuts on his nose and forehead, with fracture of the nasal bones; there was no hæmorrhage from either ear. Next day a copious discharge of clear, serous fluid came on from the left ear, containing a small proportion of albumen. On the 10th a considerable quantity of clear, colourless fluid continued to drain away. On the 12th his temperature, which had been 100° the previous night, rose to 101.6°, and he had an attack of vomiting at 10 A.M. Towards noon he was alternately drowsy and restless, and his speech was somewhat incoherent; the discharge from the ear had almost ceased. He was placed in a dark, quiet room, and his diet reduced from two pints to half a pint of milk per diem. At 1 P.M. twitching of the left leg and right arm was noticed, but in the evening his temperature fell to 101° and he became quite sensible. For two or three days he complained of pain in the head, and on Sept. 15th paresis of the left facial muscles was observed. From that time he improved steadily, and left the hospital on Oct. 11th apparently quite well except for slight weakness of the muscles on the left side of his face.

Although these two cases may be considered rather trivial to be reported, they illustrate very well how the base of the skull may be cracked without injury to its contents. The second patient would appear to have had a slight attack of simple aseptic meningitis. I may be pardoned for differing from Mr. Page, where he says that a fractured base without brain injury "need not cause you more concern than a fracture of the tibia or fibula." The course of the above cases will justify me in this slight criticism of his valuable lecture. I am indebted to Messrs. Puzey and Hamilton for permission to publish the cases, which were admitted under their care.

Bolton.

## FOUR HUNDRED CASES OF PHTHISIS.<sup>1</sup>

BY F. M. SANDWICH, M.D.,  
PHYSICIAN TO KASR-EL-AINI HOSPITAL, CAIRO.

DURING the past seven winters 104 phthical visitors have been treated by me in Egypt, and during the last two years I have had under my care some 298 hospital in-patients. The visitors have all been from England, with the exception of six from France, Australia and the United States.

### ENGLISH PATIENTS.

It is not intended in any way to make a comparison between the English and the Oriental cases, because all the former, travelling for their health, were well provided with money and friends to help them to take care of themselves. Moreover, the bulk of them were chronic cases, not suffering from fever and not in the last stage of the disease. Hence the extraordinary difference in mortality. I have taken pains to eliminate all cases of "threatened phthisis" and of doubtful delicacy after pneumonia or other diseases, because these are the cases that are obviously the best to send abroad for one winter. I have also taken some pains to inform myself as to the after-condition of patients who improved during their stay in Egypt. The 104 cases may be classed as follows: 72 improved, 18 stationary, 7 worse, 7 deaths. The seven deaths in Egypt consisted of six men—all of whom were obviously doomed before their arrival, and some of whom were only permitted to travel to Egypt under the personal escort of doctors and nurses—and an old case of fibroid phthisis, complicated by progressive muscular atrophy, who died of acute pneumonia in the less diseased of his two lungs. The number of improvements is very encouraging to those who send patients to Egypt and will compare favourably with those of other winter resorts. The majority of the patients have reached Cairo in November, have spent two or more months, from the middle of December, at Luxor in Upper Egypt, and have then spent their time till the middle of April in Cairo itself, at Helouan or at the Pyramids. In April patients go to Ramleh, near Alexandria, or more often to the Riviera, not reaching England till the very end of May. As people in England still have a very exaggerated idea about the heat of Cairo, I should like to take this opportunity of

<sup>1</sup> A paper read before the Section of Medicine at the Nottingham meeting of the British Medical Association in July, 1892.

patients in the ward. The Soudanese mortality would have been even higher if they had not included a few cases from Red Sea ports, who mostly improved in health.

*Duration of disease before death.*—It is impossible to trace chronic patients who have left the hospital, therefore I have confined myself to those who died, taking, after cross-examination, the earliest possible symptom, such as cough, which the patient could remember. Here it must be stated that the patients, not coming from an intelligent class, are apt to ignore slight ailments which do not interfere with their work. The average among the Egyptians is twelve months and a half with a minimum of one month and a maximum of five years. The Soudanese average is seven months and a half only; the maximum of three years is the only case above sixteen months' duration, while there were as many as twelve patients who had no knowledge of being ill for more than three months. It is interesting to compare these figures with the statistics of hospital patients in Europe and America quoted by Dr. Fagge. Four observers found the duration of phthisis only two years. Dr. Pollock found it two years and a half and Dr. Austin Flint two years and three-quarters. If we allow a liberal discount for inaccuracy and want of observation on the part of my patients, the figures still show the galloping tendency which phthisis has among the blacks. Of the Nubians I have unfortunately only five notes, ranging from two months to five years.

*Hæmoptysis.*—Of 36 Egyptian patients specially examined with reference to this 22 were certain that they had never had any bloodspitting, while 14, mostly men, had spat blood once or twice at the beginning of the illness. Among 83 Soudanese 75 had never had this symptom, but 8 had had it early in the illness, and 2 of these 8 had it again while in hospital. This great freedom from hæmoptysis among the lower races is interesting. Among 20 Nubians 7 had had previous hæmoptysis and 13 indignantly denied it.

*Fever* is less high among the Egyptians than with the coloured races, for while the average hectic temperature among the former was 99° in the morning and 101° in the evening, the averages among the Soudanese ranged from 99·5° to 101·4°, and among the Nubians from 99·4° to 101·8°.

#### POST-MORTEM NOTES.

Necropsies on nearly all cases were conducted by native students in my presence, but the stress of other work prevented much time being given to them, and precluded nearly all investigation by the microscope. I have already shown that most of the cases of phthisis occur among slaves and Nubians, and that the disease kills them in a very short time. I have now to point out the terribly infective nature of tubercle in their different organs. The following analysis shows that among the Soudanese more than three-quarters have tubercle in their lungs, intestines and mesenteric and bronchial glands; nearly one-half have also tubercle of spleen, one-third of liver, one-fourth of pleura and peritoneum, and about one-fifth of kidney.

*Lungs.*—Among Egyptians 14 per cent. had only one lung affected, but only one patient had both lungs free from tubercle, while 30 per cent. had cavities, large or small. Among the Soudanese only 4 per cent. had only one lung tuberculous, but 9 had no apparent lung disease, and there were cavities in 42 per cent. of the cases. Ten per cent. of the Nubians had only one lung diseased and 3 of them had both lungs free from tubercle, but 53 per cent. had cavities.

*Larynx.*—The presence of ulcers in the larynx or trachea was noted very few times comparatively, and it was an exception to find any alteration in the voice.

*Pleura.*—Tubercle of the pleura was evident in about one-sixth of the Egyptians and one-fourth both of the Soudanese and Nubians.

*Diaphragm.*—Four of the Soudanese showed small tubercles on the under surface of the diaphragm.

*Heart.*—The heart was as a rule the most healthy organ in the body, but in one case there was well-marked tubercle of the organ itself. In one Egyptian there was mitral and aortic disease. Among the Soudanese there was mitral disease in one case, adherent pericardium in another, tubercle of pericardium in two cases, and in a third patient there was a layer of tubercle an inch thick between the heart and pericardium.

*Liver.*—Among the Egyptians 14 per cent. had tubercle scattered through the liver, 10 per cent. of the livers were fatty, 7 per cent. nutmeg and 18 per cent. were greatly enlarged, while gall-stones were present in one case. In

examining Soudanese corpses I found as many as 33 per cent. tuberculous, 23 per cent. fatty and 11 per cent. considerably enlarged. One man with general infective tubercle had a nutmeg liver containing some small tubercles and an abscess the size of an orange. Among the Nubians some 14 per cent. of the livers were tuberculous, only 4 per cent. fatty, 4 per cent. nutmeg, 9 per cent. extra large, and there was one case of abscess and one case of cirrhosis. It must be remembered that many of the Nubians drink alcohol, and liver abscess is not uncommon among them.

*Spleen.*—In the Egyptians I found 24 per cent. of the spleens containing tubercles and 20 per cent. more considerably enlarged. In the Soudanese as many as 45 per cent. had tuberculous spleen, often in big cheesy centres, while 3 per cent. had spleens more than double the normal size. Of the Nubians only 14 per cent. had tuberculous spleens, while 18 per cent. of the other spleens were decidedly enlarged.

*Kidneys.*—In 14 per cent. of the Egyptians I found tubercle in one or both kidneys, while in 33 per cent. more one or both were white and large. Some 14 per cent. of the patients had a trace of albumen in the urine during life and another 14 per cent. had about one-tenth of albumen. Among the Soudanese one patient had suprarenal tubercle, 17 per cent. had tubercle, which in one case was as large as a hen's egg; 3 per cent. had amyloid and 16 per cent. white kidneys, not always large. During life 13 per cent. had a trace of albumen and another 13 per cent. had quantities varying from one-tenth to one-third. Among the Nubians, excluding congestion and simple hypertrophy, only 6 per cent. had tubercle, 6 per cent. had large white kidneys and one patient had consecutive purulent nephritis. But, curiously enough, no less than 35 per cent. had a trace of albumen during life. Here it must be remembered that very many male patients suffer from bilharzia cystitis extending to ureters and kidneys, and this doubtless accounts for the large number of patients whose urine was affected.

*Bladder.*—In one Soudanese I found tubercle inside the bladder, and outside only in cases of general abdominal tuberculosis. Once in a black I found a vesical calculus, again due to Bilharzia.

*Stomach.*—One Nubian had tubercles on the outer surface of the stomach. I only mention it because of its rarity.

*Intestines.*—After the lungs the ileum was the most common seat of tubercle or ulcers, but, unlike phthisis in Europe, ulceration was also very common below the ileo-cæcal valve, and sometimes was present in the upper colon when no ulcers could be discovered in the small intestine. Among the Egyptians 43 per cent. had ulcers in the ileum and 18 per cent. below the valve. Among the Soudanese as many as 77 per cent. had ulcers in the lower part of the ileum, besides 6 per cent. with tubercle on mucous or serous surface, and a further 10 per cent. with ulcers below the valve. Three negroes also had dysenteric ulcers in colon and rectum. Again, 72 per cent. of Nubians had iliac ulcers, 12 per cent. tubercles, and as many as 42 per cent. of these had ulceration below the valve, while two patients had chronic dysentery. One man, besides much tubercle in the upper lobes of the lungs and two large ulcers in the trachea, had 130 separate ulcers extending from the beginning of the jejunum and becoming more numerous towards the valve, and ending with three ulcers in the upper colon. In this patient the mesenteric and bronchial glands were not affected, and I often noticed that where there were many intestinal ulcers there were often no gland changes. In another Nubian, who had large cavities at both apices, caseous centres all over the lungs, greatly thickened pleura and no obvious change in the glands, there were very small tuberculous ulcers, which could be traced to the duodenal side of the pylorus, where there were three small ones. In the ileum itself there were very few ulcers, but much small tubercle on the mucous membrane. Immediately above and below the valve there were several large ulcers, and in the rectum there were a few dysenteric ulcers.

*Peritoneum.*—The tubercle of the peritoneum varied from small miliary points to a thick caseous mass an inch thick, matting together all the contents of the pelvis and lower abdomen. Among the Egyptians tubercle was present in 19 per cent., in the Soudanese 29 per cent., and my notes of the Nubians only mention 9 per cent.

*Glands.*—The bronchial glands were enlarged and cheesy in about three-fourths of all the necropsies. Mesenteric glands were affected in about four-fifths of all cases, it being a great exception to find them not cheesy among the Soudanese. Four Egyptians had great enlargement of the cervical or sub-

maxillary glands. Eight Soudanese had swollen cervical or axillary glands, while one had axillary lumps and another supra-clavicular swellings. Only one of the Nubians had enlarged cervical glands. These lymphatic glands when cut open resemble completely the caseous mesenteric and retro-peritoneal glands.

*Brain.*—About one-half of the brains were examined. In the Egyptians I never found tubercle, but in one case there was an abscess under the dura mater. Among the Soudanese I found tubercles four times in the pia mater or choroid plexus. One man had old syphilitic sclerosis near the corpus striatum. I never found any notable change in Nubian brains.

*Pancreas* tubercle I noticed once only in a Soudanese.

The ovaries were not always examined. My notes speak of tubercle once in an Egyptian, and of a case of ovarian tumour, while the Soudanese women furnished four cases of tubercle of ovary and of uterus.

*Caries.*—I have already said that necrosis and caries are very common among the negroes in the surgical wards, and certain cases of paraplegia are admitted into the medical wards. Among the Egyptians, besides a rickety dwarf and a case of angular spinal curvature, I had four cases of multiple caries of femur, necrosis of tibia and of skull, and a boy who recovered after amputation of thigh for necrosis. Soudanese vertebræ furnished us with five cases of lumbar and five of dorsal caries, besides five cases of ribs, three of sternum and one of hand. The Nubians included one case of rib disease, another of sternum and a third in which the patient died after two years' paraplegia, with healthy lungs and other organs, but with old caries of the ninth and tenth dorsal vertebræ, which had evidently begun in the anterior surface of the bodies and intervertebral discs, and had then spread to the posterior surfaces to the right of the ninth rib and to two cheesy bronchial glands.

*Entozoa* are so common at necropsies on natives that it is impossible to avoid a brief mention of them. Ascarides were present in four Egyptian corpses, once ten in number, and another time, in a boy aged seven, there were thirty-two of these worms; fourteen were curled up in the stomach, twelve in the jejunum, three in the ileum, one in the colon, one in the œsophagus and one was trying to enter the Bûstachian tube. Once I was fortunate enough to catch an ascaris that had died in the very act of boring its way through a tubercular ulcer into the peritoneal cavity. Another time a patient died three days after admission to the hospital. I found a pint of liquid green pus in the abdomen and one large ascaris lying in the peritoneal cavity between the stomach and transverse colon. The stomach was normal and no other worms were found, but a perforation was distinctly seen from the serous side of the intestine, six inches below the ileo-cæcal valve, and this was found to correspond with one of many deep annular ulcers extending from the jejunum to the descending colon. The notes of the Soudanese cases speak of ascarides five times, tœnia medicocanellata four times, and anchylostoma duodenalis twice. There was one case of anchylostoma in a Nubian peasant.

## A CASE OF ACUTE INTUSSUSCEPTION; ABDOMINAL SECTION; DEATH.

By F. W. JOLLYE, M.R.C.S., L.R.C.P. LOND., D.P.H. ENG.

My belief that cases of acute intussusception treated by abdominal section after the failure of milder treatment should be recorded induces me to publish the following case, which, although ending fatally, shows that not only may the intussusception be readily reduced, but that a child when apparently rapidly sinking should not be denied the chance of recovery that may follow reduction after opening the abdomen.

J. H.—aged eleven months, an infant at the breast, seemed well until the afternoon of June 1st, 1891, when he began to be fretful, so his mother gave him a "teething powder." In the evening he seemed in pain and was sick and passed some blood and mucus per rectum. These symptoms getting rapidly worse I was sent for at 7.30 A.M. the next day. When seen at 8.15 A.M. the child was very collapsed, with a pale, pinched expression and uncountable pulse; taking no notice of anybody, but occasionally

he moaned and drew up his legs. The vomit had no fecal odour. On palpation of the abdomen, which was not distended, an elongated tumour could be felt extending from the left hypochondrium down into the left iliac fossa, and the child flinched and drew up his legs when pressure was made over it. The right side of the abdomen felt empty and flaccid. Per rectum the finger could just detect high up the distal end of an intussusception, and on withdrawing the finger bright blood and mucus came away. Being a mile from home I inverted the child and tried inflation with a pair of bellows, but with no result, so I ordered five drops of brandy every twenty minutes until I returned. Dr. W. D. Moore came back with me at 9.30, and having confirmed my diagnosis, administered chloroform, everything being prepared for opening the abdomen if inflation failed. Injections of air and afterwards of water with Higginson's syringe, combined with inversion of the child and simultaneous manipulation of the tumour through the abdominal wall, failing to reduce it, having well surrounded the child with hot water bottles, an incision was made two inches and a half long above the pubes, and introducing my finger into the abdominal cavity found that the cæcum and ascending colon were not in their usual places, and that the intussusception extended from a little above the splenic flexure of the colon to the commencement of the rectum. Having failed to reduce by manipulation with two fingers of my right hand in the abdomen, and my left hand outside, I enlarged the incision up to the umbilicus, and with a little difficulty drew out the tumour on to a warm sponge-cloth, and, steadying it with my left hand, with my right I gently squeezed the distal end, and in a few seconds the proximal end gradually commenced to unfold itself, and as the unfolding went on I followed up the distal end, and had no difficulty in reducing it until I came to the last two inches, which required several minutes' very gentle manipulation to free it. The intussuscepted part, which was intensely injected and flaccid, consisted of the lower part of the ileum and cæcum, as was suspected before the operation. There were a few flakes of recent lymph near the junction of the sheath and entering bowel, and a little blood-stained serum escaped on opening the abdomen. During the operation the child became pulseless, but rallied after a subcutaneous injection of brandy; the abdomen was not washed out as it was desirable to finish the operation as quickly as possible. After the dressings were applied the child was very collapsed. After several subcutaneous injections of brandy he rallied a little, but half an hour after the operation the pulse was so feeble that it could not be counted at the wrist. The child was ordered a teaspoonful of warm water every hour, and half a minim of tincture of opium and ten minims of tincture of belladonna every three hours if in pain. At 7.30 P.M. the child was quite bright and played with anything that was given to it; there had been no sickness, but he was very restless at times and had only passed, the mother said, a little flatus once with no motion. He was ordered a teaspoonful of his mother's milk every other hour through the night.—June 3rd: He had had a very restless night and was sick twice, but had slept for three-quarters of an hour, about 8 A.M. He had passed no flatus, or motion, his countenance was pinched and his eyes sunken; the abdomen was a little distended; pulse 120; temperature 100.5°. He was given several soap-and-water injections, but nothing came away except a little mucus and blood. In the evening, as his abdomen was rather more distended, he was given a little chloroform, and the three lowest stitches were removed, with the intention of irrigating the abdominal cavity, but he became so collapsed after the tube was introduced, that it was thought better to desist. The wound was quite healthy and the edges were with difficulty separated. He died at 12.30 A.M. the next morning, and no post-mortem examination could be obtained.

*Remarks.*—This case was certainly much more acute than the generality of cases of acute intussusception, for within fifteen hours the child was in a collapsed and dying condition, and the only hope of saving him was to open the abdomen immediately inflation failed. The fear was that he would die on the operation table. The operation, although it relieved the intussusception, did not relieve the obstruction, the gut never recovering from its strangulation; and the child died, no doubt, from intestinal obstruction caused partly by this strangulation and partly by the peritonitis which had commenced before the intussusception was reduced, and which continued afterwards.

Alresford, Hants.

No doubt within the last twenty years sanitary progress has been made in some rural districts, whereas in many others the conditions remain very much as they were before the boards of guardians throughout England were invested with the additional duty and dignity of rural sanitary authority. Is it that the condition of the rural population in these districts is so absolutely *comme il faut* that nothing needs to be done? Very few country dwellers outside the boards of guardians will admit that. The years slip past and little or nothing is done. The offensive cesspits, foul ditches and collections of filth remain to breed fevers; the drinking water is as polluted and dangerous as ever; the houses that were old and crazy are the same in a superlative degree, and many of those of more recent erection are damp, inconvenient and unwholesome, being almost always erected with the object of securing a large interest for money invested rather than of supplying the want of decent homes for the labouring class. The result is very visible everywhere. It is not too much to say that half the acute illness in old and young is due to it, to say nothing of the chronic affections and broken health engendered by the consequent exposure and privation. How often do we see in country districts the poor growing prematurely old, their limbs twisted with rheumatism and their powers crippled by chronic heart and lung diseases, drifting into the workhouses, putting the funds of their clubs to a strain, or swelling the visiting list of the parish doctor, when they should be in the hale prime of life? That the best health is always to be found in the best house is a safe axiom, other things being equal.

Overcrowding exists in rural districts to a large extent, and its ill effects cannot be exaggerated and are too patent to need enumeration; but the moral side of the question is a striking one. Illegitimacy and overcrowding must be nearly related. In the Amptill Union, where until quite recently there was a standing resolution that made 150 cubic feet of sleeping space per adult person a sufficiency (which had the convenient effect of shelving the subject of overcrowding), the illegitimate birth-rate has averaged 8 per cent. of the entire birth-rate, or about one such child in every twelve born. Considering that the illegitimate child is often an only child, whilst legitimate children probably average four or five in a family, the above fact constitutes a serious indictment against central Bedfordshire, and the same may be said of many another district. In Bedfordshire, as elsewhere, many houses have been built by labourers and others upon the roadside waste, the sites being often cramped, damp and unsuitable, and the result is the present existence of numbers of wretched places that never were or could be healthful. In times past houses have been put up in any place or style, being subject to no sort of inspection or control, and in numbers of places, no by-laws having been made, the same thing may still continue, excepting that there are now no free sites, as the roadside waste is no longer a no-man's-land. Numerous old thatched cottages of an ancient type are also extant, the bedrooms being in the roof, mere lofts with or without windows. Old rows are met with here and there originally put up for fagot voting, and many houses are found almost everywhere throughout rural England of very inadequate size and convenience for the large families that occupy them. Many of the habitations of the rural poor are not worthy of the name of houses, and undoubtedly the greater conveniences and comforts of town houses over those of the country form one reason why the countryman never returns to the village when once he has migrated into the town. In Italy and parts of France one notices that the poor are housed on a different principle to ours, being located in tall houses let out in flats. I have had no opportunity of noting the actual accommodation, but the houses externally have a much less meagre appearance than our poor cottages. The table appended shows the size and population of some cottages examined in the Amptill Union.

The general impression gained on inspecting the cottages is that there are many houses in a wretched condition, often great overcrowding, with unhealthy surroundings, such as pigsties and middens. Many of the houses, being built on the roadside waste, are cramped for space and have no gardens. Some cottages consist of two rooms, one up and one down, and a great many have only two bedrooms. Beds are often crowded in the bedrooms, which have small windows and insufficient ventilation. It is sometimes necessary to get over one bed to get into the further one. The rents of older places are 1s. 3s. and 1s. 6s. a week. On the western or Buckinghamshire side of the Union some lace making is carried on in the cottages. By working all day a woman can make a yard of narrow lace, which she sells for sevenpence. On the eastern side of the Union a few women are employed in straw plait and hat making. Straw plaiting used to be such a good trade that the men preferred to stay at home to work at it rather than work in the fields. This industry has been ruined by the importation of Canton plait and the introduction of plaiting machines. For twenty feet of plain straw plait threepence is now paid, and a woman works hard to earn two shillings a week. At Maulden and elsewhere plait is given out to be sewn into hats. Plain hats are sewn together at the rate of ninepence and a shilling a dozen.

Much remains to be done in regard to the drainage of villages and village towns. The best mode of sewage disposal for villages is perhaps not satisfactorily arrived at, but the old system of privy vaults or cesspits is undoubtedly the worst system, and as such should be suppressed. It is still almost everywhere in vogue, generally in conjunction with a water-supply from shallow wells. But under any circumstances a system of drainage is necessary to carry off slops and waste waters used for washing, culinary purposes &c. Wherever there is an aggregation of houses drains are required or a nuisance is sure to be caused. At present in many villages there are either no drains, the waste waters being thrown round about the doors, or a few rude pipes lead from a sink into the nearest ditch, which is consequently liable to become foul and offensive. The sanitary authorities have power to make drains in every village, but when such a matter is brought forward it is generally again and again postponed. Sometimes also, when drains do exist, their condition is such as to render them almost as dangerous as the old cesspits, so badly have they been constructed; or it may happen that new public drains or sewers having been laid down, the authority has failed to make the owners of houses drain into them. Some of the sewers have also been

very badly laid. The local bricklayer has been allowed too often to do the work according to his own ideas, there having been no proper survey and nobody to make one, for there is no officer in rural districts corresponding to the urban surveyor.

As to the disposal of sewage in villages, the question constitutes a very general difficulty. In numerous instances sewage continues to be discharged direct into brooks by right of long usage. When treatment is suggested difficulties are certain to present themselves. Somebody's interest is at stake to prevent acquisition of land for irrigation; what was good enough for their fathers is good enough for them, they argue, and point to the manure in their farmyards as an instance of the harmlessness of sewage. Then the expense of the thing, who is to bear it? The village may consist almost wholly of cottagers whose average wage is perhaps 12s. a week, upon which a family can only be poorly sustained. The whole Union will not provide benefit for the single parish. The whole parish will not provide for the limited area that is to be benefited. The large farmers upon whom the chief weight of taxation would fall are probably guardians who are not willing to tax themselves for the sake of what they consider to be a doubtful benefit for the labourers of the village. So the undrained premises, polluted wells and wretched dwellings remain. In a large village a scheme of drainage has been under consideration on and off for five-and-twenty years and nothing had been done up to 1892.

With regard to water-supply, this is often very inadequate to the requirements of the villages both as to quantity and quality, being so frequently derived from a few shallow wells. Some thirty analyses of well waters taken at haphazard from wells in Amphill pointed to the likelihood of 100 of the 200 wells there containing water unfit to drink. At Marston Moretaine the people have a choice of three pumps situate upon three separate premises, the remaining houses being destitute of any supply. A small sum per bucketful is or was charged by the proprietor of one or two of the pumps for the water. The favourite pump yields a water of bitter and saline quality, containing an enormous amount of inorganic solids—a mineral water, in fact, of greater strength than that of some of the spas. The water has often to be carried for long distances at immense inconvenience and labour. These are instances of a very general state. In some cases a better supply could be obtained at small expense. The rural sanitary authorities are as yet scarcely awake to their full responsibilities and powers. They shirk the onus of borrowing capital to construct drains and waterworks, and it does not strike them that the prevention and spread of disease are to a large extent in their hands, and that disease and premature death may be and are caused by their negligence in not carrying out necessary reforms. The delay in adopting the Notification of the Infectious Diseases Act and supplying accommodation for the isolation of infectious diseases, for instance, must have been the cause of incalculable mischief. Other and larger duties devolve upon a rural sanitary authority than the simply initialling by its chairman of the minor items in the inspector's book; yet too often this has constituted the sole business, the good done being little more than nominal. The power of the sanitary staff is immensely increased by a good code of by-laws, but some of the rural sanitary authorities appear to think that by-laws are intended for urban districts solely, and will have none of them. In the majority of rural districts no proper system of disinfection is carried out; sometimes a little money is expended upon the purchase of disinfectants, and a few bottles of carbolic acid &c. are distributed; but it is a grave question whether much good results from such imperfect methods. Disinfection of bedding and clothing by heat is a rare practice, and sulphur fumigation is irregularly performed. The houses being often so overcrowded as to be injurious to health at the best of times, isolation at home is quite impracticable, the conditions on the contrary being such as are highly favourable to the spread of the zymotic diseases, yet rarely have isolation hospitals been erected.

Altogether there is much sanitary work to be done in rural districts. Little is yet accomplished, and little likely to be accomplished under the present régime. The rural sanitary authority is formed of the chief ratepayers of the district, many of whom are farmers or others who live in isolated houses, and who reap no direct benefit from the expenditure of money on sanitary improvements, whilst they have to contribute the chief share of the cost. The knowledge of its members, again, in the main,

is not sufficient to enable them to appreciate the benefits accruing from an improved sanitary condition of the villages, whilst they are prejudiced against innovation and conservative of old methods which have existed throughout their lives and those of their forefathers. Moreover, they have little time to devote to questions of public health, and are unready to take up any matter which is likely to bring them under the fire of public criticism, especially if the borrowing of a few thousand pounds is necessitated; yet they not infrequently fritter away in small items and half measures an annual sum that would pay interest on a large borrowed capital, and also pay up the capital itself within a reasonable number of years.

As respects the medical officer of health who is appointed to advise the rural sanitary authority, he holds a very invidious position. The whole question of village sanitation initially rests with him, but his salary is generally so absurdly small, perhaps averaging £60 per annum, that it is often more than absorbed by the expenses of getting about the Union, which may contain twenty or thirty parishes and have an area of 200 or 300 square miles. The first part of his time is devoted to his private professional work; or if he be not in general practice he is obliged to undertake a combination of unions in order to make a respectable income, so that it is utterly impossible for him to cover the ground, which may extend into several counties. The presence of the medical officer of health at the meetings of each board is no doubt salutary, but to attend all the meetings is in the one case impossible or would absorb all the time, and in the other case is worth more than the whole salary paid, especially as boards of guardians show very little appreciation of a medical man's time and will keep him waiting whilst other business is in progress, as if he had nothing else to do. As regards the salary paid to the medical officer of health and the size of his district, the matter lies rather in the hands of the Local Government Board than with the board of guardians, inasmuch as every appointment is confirmed by the higher authority.

The present rural sanitary administration is therefore unsatisfactory from several points of view, and is ineffective and wasteful. It is usual to put the blame upon the laws, and no doubt the Public Health Acts are too permissive in character and too vague and limited in definition; but much good work has been done under them in towns, and much might be done in the country if they were properly administered. A change must be made, and the duty may fall upon the County Councils, which do not appear to be overburdened with work at present, to act as central sanitary administrators and manage the finance. The parish or district councils that have been promised, on the other hand, which from their very number must be constituted differently from boards of guardians, could enter into the details of their own requirements. The medical officer of health who would be appointed to such a part of the county as is compatible with an active supervision, giving his whole time to the duties, could be called in at every parish meeting where sanitary business was to be discussed, to supervise the sanitary work of his district, and to give an account of the same to the County Council at its quarterly meeting. He should also have a seat on the Council Board and give advice when called upon. A county sanitary rate would be required. Should the County Council, being moved by party politics or otherwise, decline to defray the cost of the sanitary improvements voted by the parish or district council and recommended as necessary by the medical officer of health, an inquiry by the Local Government Board could be held to settle the point of necessity.

Cheltenham.

## PERMANGANATE OF POTASH IN THE PREPARATION OF FRESH SECTIONS.

By E. T. WYNNE, M.B. CAMB.,  
PATHOLOGIST, COUNTY ASYLUM, RAINHILL.

For the past nine months I have been using permanganate of potash as a fixing reagent in the place of osmic acid for preparing fresh sections of the central nervous system, checking the results by Mr. Bevan Lewis's method. Though this reagent may not surpass the best results obtained with osmic acid, I have found it more trustworthy for every-

day work and more expeditious. I need hardly point out that it is much cheaper. Permanganate has of course long been known as a powerful fixing reagent, but I have been unable to find any evidence of its use in the preparation of fresh sections. As I have given it an extensive trial I wish to bring it to the notice of histologists, and more especially of demonstrators and others who have to prepare large numbers of sections for classes. By this method two operators (one to cut the sections and the other to carry them through the fixing process) could easily prepare sufficient sections for a class, without an inordinate expenditure of time. The sections are quite permanent. The steps in the process are briefly these: The sections are cut with a Cathcart or some similar microtome, and each as it is cut is plunged (on the knife) into a 0.1 per cent. solution of permanganate. The section must not remain more than ten seconds in the solution (four to five seconds is plenty for normal brain), but be taken out on a glass lifter<sup>1</sup> and transferred to a basin of clean cold water. The sections will be found slightly tinged yellow. This comes out in the process of washing and staining. The sections, which have been accumulating in the basin of water, are now put into a 0.25 per cent. solution of blue black (or a 0.1 per cent. solution of china blue), where they remain from ten to fifteen minutes. A large quantity of stain should be used and care taken that the sections are freely exposed to the dye. When stained they must be well washed in water, picked up on slides and allowed to dry. The best results are obtained by allowing them to dry slowly over night, but with care they may be dried in about an hour in a warm chamber. There are three points of importance—viz., to see that the water and permanganate solution are cold, to wipe the under surface of the knife-blade after cutting each section and not to freeze the tissue hard—it should cut like a potato. I use a deep quarter-plate developing dish for my permanganate solution. In it the knife can be readily submerged without wetting the handle and without having an inconvenient depth of fluid.

While on the subject of fresh section cutting, I should like to help in the removal of what seems to be a very widespread superstition with regard to the keeping of solutions of osmic acid. Osmic acid solutions are generally to be found swaddled up in brown or orange paper, or in "non-actinic" bottles, and kept huddled away in the darkest corner of a cupboard, under the impression that this will prevent decomposition. These precautions are quite unnecessary, and, unless the points to be mentioned are observed, quite useless. I have kept solutions of osmic acid over a year without any protection from light. Though they have been in daily use they are as good as when first bought (except for a diminution in strength, due to volatilisation). To keep osmic acid the bottle in the first instance must be clean. This is ensured by rinsing it out with strong nitric acid and then with distilled water. The only other precaution necessary is to wipe the neck and stopper of the bottle before using the acid, so that no dust may fall into the solution. The advantages which permanganate offers over osmic acid are these: (1) Its cheapness. (2) The solution is of a known strength, which can hardly ever be the case with osmic acid. (3) It is quicker, and by using it the section has not to be floated off the knife before being put in the fixing solution.

Rainhill.

<sup>1</sup> The lifter is a glass rod drawn out to a point and bent at an angle.

**FRIENDLY SOCIETIES' MEDICAL INSTITUTE, NORTH-AMPTON.**—The annual report of this institute just issued records a membership of 14,369. The income of the Society is somewhat less favourable than last year, as compared with the expenditure; but this is accounted for by the outlay necessary for the supply of new fittings. The death of the late assistant medical officer, Mr. J. N. Whitfield, was referred to in terms of regret for the loss of his valued services.

**HOW INFECTIOUS DISEASE IS SPREAD.**—A grocer's assistant was summoned last week at the Rotherham police court for being in a shop while suffering from an infectious disease. He went to his shop when recovering from an attack of scarlet fever, whither the doctor followed him and found him weighing up articles for sale, the defendant at the time being in a highly infectious state. The magistrates, in view of the expense to which the defendant had been put, imposed a fine of only 20s. and costs.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL.

#### SPASMODIC ACTION OF THE LOWER JAW OF SIX YEARS' DURATION CURED BY OPERATION.

BY NOBLE SMITH, F.R.C.S. EDIN.,  
SURGEON TO ALL SAINTS CHILDREN'S HOSPITAL.

ON March 26th of this year B. M.—, aged twenty-nine, came to me suffering from a spasmodic action of the lower jaw. There was a powerful grinding movement of the teeth, the lower jaw acting spasmodically towards the right continuously. This affection had commenced six years previously after an illness brought on by cold and involving paralysis of the left leg and back, for which she was laid up for six months. The teeth also became carious about this time. During the last four years the spasms had been very severe and continuous, and the pain and distress which the affection caused were becoming, the patient declared, "almost unbearable." The teeth were to some extent worn away by the constant grinding action. The temporal muscle and the pterygoids on the left side and slightly on the right were occasionally in action, but the muscle which acted incessantly and most powerfully was the masseter of the left side. I sent the patient to Mr. Collyer, who kindly extracted some teeth and informed me that he had removed every apparent source of dental irritation. There was some relief to the severity of the spasms after this, but it only lasted a few days. Mr. Collyer said he could do nothing more unless he extracted all the teeth that remained. Upon this I advised operation on the nerve supplying the masseter muscle. The patient was first seen by Dr. Hughlings Jackson and by Dr. Gowers.

The operation was performed on June 27th, Mr. Davis administering the anæsthetic. I made a vertical incision from the centre of the zygomatic arch downwards, and exposed and carefully dissected out the transverse branches of the facial nerve. Holding these branches aside, I cut down upon the masseter muscle, divided the oblique fibres and exposed the vertical, through which I cut towards the sigmoid notch, where I met with the masseteric branch of the inferior dental nerve, from which I removed a quarter of an inch. From this time all spasm of the jaw ceased, and it has not returned. It is needless to endeavour to describe the relief to suffering which the patient has experienced from the cessation of the spasm after six years' continuous pain and worry. She is nervous, fearing that the spasm may return, and sometimes, she says, gets a little twitch of the mouth, but there is nothing apparent to observation. In operating I accidentally wounded Stenson's duct, and there was a flow of saliva from the cheek for about a week. With a few applications of nitrate of silver the minute opening soon healed up. The rest of the wound had healed by first intention, and now there is only a trace of the incision.

Queen Anne-street, W.

#### HYPERTROPHY OF THE MUCOUS MEMBRANE OF THE UPPER LIP.

BY WM. ERNEST MILES, M.R.C.S., L.R.C.P. LOND.

THE case I am about to describe is of interest, not only because examples of hypertrophy of the mucous membrane of the lips are by no means of common occurrence, but because it illustrates the tendency to recurrence of these tumours *in situ* after removal by operation, unless that procedure is efficiently carried out.

A. M.—, a male inmate of Broadmoor Asylum, drew my attention to the existence of a small pendulous growth arising from the inner surface of his upper lip, a little to the left of the frenum and extending in an outward direction for the space of about an inch. The growth was not noticeable when the lips were closed, but presented a somewhat unsightly appearance when the patient spoke

or laughed. It had been slowly increasing in size and latterly had become a source of annoyance to him during mastication. Previous to his admission here he tells me he had been troubled with a similar growth in the same situation, which he removed himself with a pair of scissors. A cure however was not effected, since, very soon after the wound had healed, the growth again began to make its appearance, and had now become troublesome in the respect I have mentioned. Recognising the case to be one of hypertrophy of the mucous membrane, from the nodular and shotty character of the contents of the tumour, I decided upon removing it with the knife. This I did by means of an incision carried round the base of the tumour, taking care not to encroach upon the free margin of the lip. Having removed the superabundant tissue, I noticed several small yellowish-white bodies about the size of a split pea (the hypertrophied labial glands) scattered over the surface of the wound. These I removed carefully by means of a pair of dissecting forceps and then closed the wound with horsehair sutures. The wound healed by first intention, leaving no deformity, and although it is now some months since the operation there is no sign of a recurrence of the growth. Mr. Bryant has shown that this hypertrophy is due to an overgrowth of the labial glands and that unless these are all removed the growth is likely to recur. When my patient performed the operation on himself several of the hypertrophied glands must have escaped removal, and I have no doubt it is to this fact that the recurrence of the growth *in situ* is to be attributed.

Broadmoor, Berkshire.

#### DISLOCATION OF THE RADIUS BACKWARDS AT THE ELBOW-JOINT.

BY LEWIS E. PARKURST, B.A., B.CH., B.M. OXON.

On August 1st I was called to Mr. B—, aged sixty years, who had been thrown out of a dogcart, alighting on the palm of his left hand. I saw him within ten minutes of the occurrence of the accident, and before any swelling had arisen. His arm was semiflexed at the elbow and midway between pronation and supination, and it could not be moved without causing great pain. The elbow was found on inspection to be greatly increased in breadth when viewed posteriorly, and there was a prominence behind and just above the external condyle of the humerus, which was found, on rotating the hand, to be the head of the radius; the latter could not be felt in its ordinary position. The nature of the accident was clear and unmistakable, and that it had been caused by a fall on the hand was apparent both from the patient's statement and the existence of an abrasion of the skin over the ball of the thumb. Reduction was easily effected by extension of the forearm followed by traction, and the patient was at once able to move his elbow and fingers. The arm was put up at a right angle on a moulded posterior angular splint, and he travelled home next day. Mr. de Mesquita, house-surgeon to the Croydon General Hospital, who subsequently attended him, has kindly informed me that the progress of the case was in every way satisfactory.

This is a very rare accident. Professor Langenbeck of Göttingen, in giving an account of the only two cases of dislocation of the radius backwards" (at the elbow-joint) "must be an extremely rare occurrence, since Sir Astley Cooper<sup>1</sup> never met with this accident in the living and only once in the dead subject."

Brackley, North Hants.

CLINICAL HOSPITAL, CHEETHAM-HILL-ROAD.—On Monday was opened, without any public ceremony, the new wing of the Clinical Hospital for Women and Children, Park-place, Cheetham-hill-road, for the accommodation of out-patients. The total outlay amounts to £2000, which has been raised by subscription.

PROPOSED NEW PARK.—There is some talk of converting the site lately occupied by the Wild West Exhibition into another breathing space for the inhabitants of London. A conference is now being arranged for by the parishes of Kensington, Fulham, Hammersmith and Chelsea to consider the new project, the estimated cost of which is £25,000.

### HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

#### GREAT NORTHERN CENTRAL HOSPITAL.

A CASE OF TETANUS, WITH PROLONGED LOCKJAW,  
SUCCESSFULLY TREATED BY CHLORAL AND  
CHLOROFORM.

(Under the care of Dr. CHOLMELEY.)

THE successful treatment of tetanus is a subject which possesses constant interest for members of the profession, each case affording useful data for future help. It is true that this case presents characters common to the large majority of cases successfully treated, and the course was essentially chronic. We have recorded many instances of recovery from tetanus. In 1887 Mr. Meldon<sup>1</sup> read a paper on this disease and gave statistics of 937 cases collected by him. He had administered hyoscyamus, belladonna and conium in 17 cases, with only 4 deaths, in his own practice. Of the other cases, in 370 treated by chloral 83 recovered and 287 died; in 135 treated by curare 23 recovered and 102 died; 60 by nicotine, 3 recoveries, 57 deaths; 96 by opium, 4 recoveries, 92 deaths; 21 by conium, 3 recoveries, 18 deaths; 76 by cannabis indica, 12 recoveries, 64 deaths; 28 by bromides, 2 recoveries, 26 deaths; 103 by alcohol, 25 recoveries, 78 deaths; 41 by all other remedies, 17 recoveries, 24 deaths. He excluded from this table those in which the first symptoms were noticed later than the fifteenth day. In 16 cases which we have published in our columns since the appearance of that paper chloral hydrate was employed in 5 and bromide of potassium in 8; hydrochlorate of morphia, strophanthus tabloids and extract of physostigma in others; in 7 morphia was also used for the relief of pain. These, again, are not examples of the more acute form of tetanus, for the period which elapsed between the receipt of the wound and the onset of the disease varied from four days to four weeks. In the majority of cases the use of chloral produced the most marked effect, conjoined with rest and the due administration of fluid nourishment. Verneuil in 1885 recommended strong doses of chloral and bromide, with quiet &c.; and in the previous year a similar line of treatment was advocated by the Royal Academy of Medicine in Ireland. Of late there has been little new to record in the treatment of tetanus; the questions of immunity, infection &c. have, however, attracted much attention. Many experiments made with chemicals, to test their action towards weakening or destroying the cause of tetanus, have so far yielded no specific, nor indeed found a useful remedy. There are some cures announced after an extended trial of subcutaneous injections of carbolic acid. The use of chloroform to allay spasms, procure sleep and permit of proper feeding was most successful in the following case, and when this remedy is used the symptoms are usually very severe.

S. N—, aged seven, was admitted on July 22nd, 1892, with the following history. He had run a small but dirty splinter of wood into the palm of his right hand about three weeks previously. The small wound had not healed properly, but remained in an unhealthy-looking condition; a few small vesicles of watery pus occasionally formed around it. On July 18th his parents noticed that his face was apparently drawn to the right side, but as he did not seem ill he was allowed to go to school, where he was able to join in the play as well as the work and showed no symptoms of illness. On the following night he was convulsed several times, but was better in the morning and again attended school. At night the convulsions returned and he could only open his mouth a little way owing to the continued muscular spasm.

When admitted to the hospital two days later the boy was said to have taken no food for the previous forty-eight hours. His jaws were firmly fixed, his whole body was

<sup>1</sup> THE LANCET, vol. ii. 1887, p. 817.

rigid and he could only just stand. His back was arched, his abdomen as hard as a board, his head retracted, the features drawn into a grin, but he did not complain of actual pain. Attempts to feed him with a tube only resulted in still more violent spasm, the whole body being thrown into the position of opisthotonos. The spasm was, indeed, so severe that the respiration nearly ceased, the patient becoming rapidly livid. Chloroform was at once administered and the spasm passed away under complete anaesthesia. The jaw could then be opened and, a gag being inserted, the mouth was explored, but nothing abnormal discovered, with the exception of a pellet of chewed paper at the back of the tongue. By means of a nasal tube a mixture of milk, beef-tea, yolk of egg and brandy was passed into the stomach and retained, and fifteen grains of chloral hydrate were given in the same way. The child slept well for several hours, the spasm of the abdomen and limbs being quite relaxed and that of the jaw nearly so. On waking the boy seemed quite conscious but drowsy, and an attempt to feed him in the ordinary way was made, but only with the result of producing recurrence of the spasm and the necessity for the further use of chloroform. Vomiting occurred once, and for the moment the jaw spasm was relaxed, but rapidly came on again. The spasm of the trunk muscles was unaffected. There was no relaxation of sphincters.

On the second day after admission it was found possible to feed by the mouth by sips sucked through the teeth, but this improvement did not last long, and again the feeding tube had to be resorted to under chloroform and large doses of chloral administered, doses varying from ten to fifteen grains being given at longer or shorter intervals as the severity of the spasms required. This condition continued until July 31st, the child becoming very thin, the superficial veins of the trunk being very prominent and general cyanosis coming on at intervals. The pulse remained fair; the temperature never rose above 99° and the bowels acted. Steady improvement began to be noticed during the first week in August, and by degrees the general muscular spasm and finally the spasm of the jaw completely passed away and the use of chloral could be suspended with safety. The patient made an excellent and complete recovery. The case was carefully watched and very judiciously handled by Mr. Gordon Calthrop, the house physician, to whom most of the credit for the successful issue is due.

## EASTERN FEVER HOSPITAL.

### TWO CASES OF GLANDERS.

(Under the care of Dr. COLLIE.)

THESE two records of patients who died from glanders are of considerable interest at the present time, when the disease is attracting much attention, and it is important to observe that both were sent to the hospital with the diagnosis of typhoid fever, and this suggests the possibility of similar cases being treated at their own homes for that disease, when really they are examples of the much more serious one of glanders. It will also be noted that the first patient was taken into hospital in 1890, the second in August, 1891. We have recently in an annotation<sup>1</sup> drawn the attention of the profession to the dangers attending the prevalence of glanders in horses in various parts of the kingdom, and these cases further prove the necessity for much greater stringency on the part of the Government in the treatment of horses suffering from the disease. The great risk run by those attending on the horses is shown in Case 2, where the effect of sneezing on the part of the horse appears to have been sufficient to cause inoculation in that patient. "There is only too much reason to apprehend that not a tithe of the cases of glanders occurring amongst horses in London and the provinces are reported to the sanitary authorities." It is a disease which rigid supervision should stamp out. For the notes of the cases we are indebted to Mr. James Dickinson, late assistant medical officer.

CASE 1.—F. H., a male, aged twenty-five years, was admitted to hospital on Dec. 24th, 1890, certified as suffering from enteric fever. History obtained on admission: Ailing for some time. The patient was seized with shivering on Dec. 17th and since the 19th had been delirious. On admission he was delirious and was restrained with difficulty. Aspect suggestive of pneumonia, but no physical signs detected.

Dec. 25th.—Bloody matter in sputum; no physical signs found in chest. Throat generally reddened, hyperæmia over chest. Abdomen retracted; no tenderness; no diarrhoea.

27th.—Physical signs of consolidation detected over right back. Cough troublesome, with plenty of blood-stained frothy sputum; a cloud of albumen in urine. The patient grew weaker from day to day and wasted visibly. The cough was incessant, the sputum blood-stained and copious. The signs of consolidation became more extensive over the right back and appeared also on the left. Otherwise the man's condition did not present any markedly new features till the date of the following notes.

Jan. 5th, 1891.—Very prostrate, semi-conscious and inclined to mutter. Could protrude tongue, but with great difficulty, when bidden sharply. Respiration very rapid; pulse almost uncountable. All dejecta passed into bed; there had been seven motions in the previous night. Discharge from nose and left eye; the discharge from the nose had been first noticed the day before; it was then slight and watery; it was now thick and copious. On making the man blow his nose there appeared a quantity of yellow purulent matter and a large piece of tough membrane. Scattered over the trunk and limbs was a scanty eruption of papules, vesicles and pustules. One or two pustules had been noticed on the previous day. Each vesicle and pustule was surrounded by an area of injected skin. They rapidly increased in size, so that in a few hours from their first appearance they were all sizes, from that of a pin's head to that of a shilling. There were also several intense erythematous patches, all seated over joints. The joints themselves appeared to be unaffected. Deep-seated fluctuating swellings were detected in both calves and over one shoulder. No glandular swellings.

6th, 1.30 A.M.—Death.

The course of the temperature throughout is shown on the accompanying chart.

*Necropsy, fourteen hours after death.*—Pericardium unaltered; heart dilated and laden with fat. Recent pleural adhesions all over right lung; a few adhesions on left side. Right lung nearly solid throughout, with extreme emphysema at apex and anterior margin; it had a very lumpy feel and was of an intense deep-red colour, except where areas of emphysema stood out, owing to the engorgement of the bloodvessels, a bright vermilion. The condition appeared from subsequent microscopical examination to be a mixture of pulmonary apoplexy and lobular pneumonia. The left lung presented a less degree of the same condition. Both broke down easily under the finger. The throat and larynx were not remarkable; nasal fossæ not examined. The alimentary canal was examined throughout without noteworthy result beyond extreme injection and catarrh of the small intestine; the normally solid abdominal viscera were all of rotten consistence; the spleen contained one large infarct; the kidneys weighed 1½ oz., were rather pale on section, but the structure stood out with remarkable distinctness; under the capsule was a layer of intense injection; no pus in any of the joints; there were several collections of dirty-looking pus seated in the substance of muscles, particularly the calf muscles; when the skull-cap was taken off several loose collections of pus appeared between it and the dura mater; beneath the dura mater and the brain were several similar collections; there was universal injection of all the cranial contents.

History subsequently obtained from the brother: The man's work was all amongst sick horses. He had "to put the balls down their throats," and had more than once been bitten so as to draw blood. He had been ailing for two or three months from headache, cough, loss of flesh and weariness, but his doctor had told him he was not ill enough to throw himself on his club. He kept to his work, but with great difficulty, up to Dec. 17th. When he reached home on that day his knees gave way under him, and he was put to bed. He did not rise again.

CASE 2.—S. C., male, aged twenty-six years, was admitted to hospital on Aug. 14th, 1891, certified as suffering from enteric fever. The history brought with the patient was that he had been delirious for some days. On admission his breathing was rapid, and physical signs of pneumonia were at once searched for, but without result. No rash. There was a small pustule on the abdomen.

Aug. 15th.—Night. Breathing rapid and panting. Some impaired resonance at bases, but no other physical sign detected over lungs. Heart: action very rapid; no increase of cardiac area; no murmur. Patient semi-conscious. Urine passed freely into bed. There was an eruption of pustules each surrounded by a red area distributed over trunk, limbs

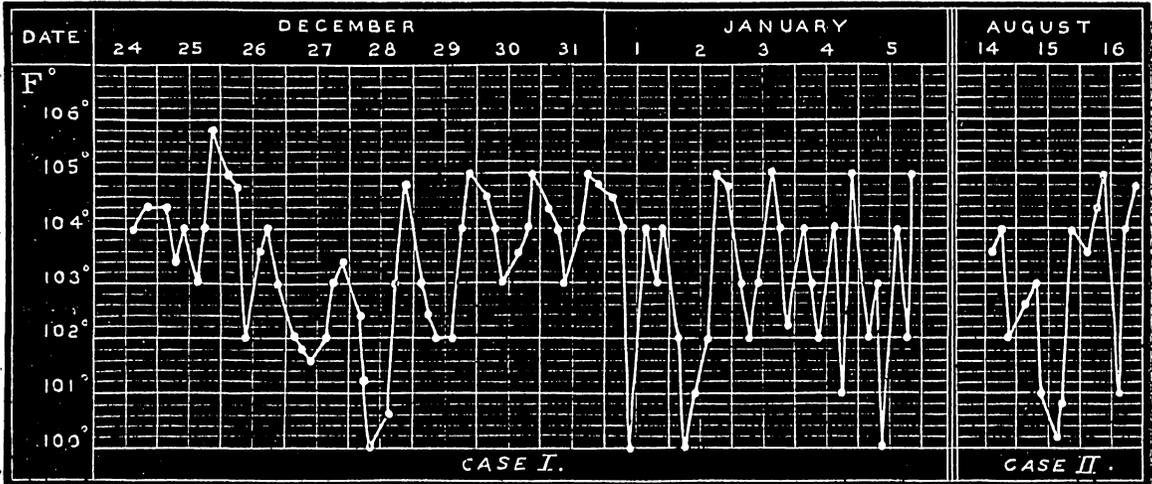

<sup>1</sup> THE LANCET, vol. II, 1892, p. 207.

neck and face. The pustules varied in size from that of a pin's head to that of a sixpence. From the appearance of the eruption glands was at once suspected and fluctuating swellings were looked for and several detected in the calf muscles. No discharge from nose or eyes; no cough; no diarrhoea. The finger-joints of both hands and one elbow-joint were swollen and red.

16th.—Eruption very copious. The individual pustules had increased very much in size and some were larger than shillings. Several large ones were broken in the centre and

17th.—1.40 A.M.; death. The course of the temperature is shown on the chart.

*Necropsy, thirty-six hours after death.*—Heart dilated and laden with fat; muscular substance rotten. No pleural adhesions. Lungs deeply congested and very oedematous; no consolidation. Kidneys weighed 16oz.; capsules moderately adherent. The cut surface had a purple-mottled hue, and the cortex could scarcely be distinguished from the pyramid. There was pus in the finger-joints and one elbow-joint. There were many intra-muscular and subcutaneous collections

seemed to be drying up. Blood had been effused into some of them and there were one or two large vesicles containing blood-stained serum. There were many fluctuating swellings, some deep-seated in the calf and arm muscles, some subcutaneous. There was a hard swelling as large as a filbert and crowned with a petechia in the glans penis. Urine was drawn off by catheter for examination. It contained a dense cloud of albumen. No discharge from nose or eyes; no glandular swellings; no fresh joints affected. At night the patient became comatose, snoring loudly.

of pus. All the other important organs were examined without definite result.

The following history was subsequently obtained from the father. The patient, in addition to his work as shopman, had charge of some horses. A horse with discharging nose sneezed in his face five weeks before admission. Two days later the man complained of pains in his limbs, headache and shivering. He did not take to his bed till a fortnight before admission. The horse died before the man.

## Reviews and Notices of Books.

*Geographical Pathology: an Inquiry into the Geographical Distribution of Infective and Climatic Diseases.* By ANDREW DAVIDSON, M.D., F.R.C.P. Edin., late Visiting and Superintending Surgeon, Civil Hospital, and Professor of Chemistry, Royal College, Mauritius. In Two Vols. Edinburgh and London: Young J. Pentland. 1892.

IN these two large handsome and well-printed volumes Dr. Davidson essays a laborious and difficult task—viz., a general survey of the distribution of infective and climatic diseases throughout the globe. "The object of this work," the author says in his introduction, "is to sketch the geographical distribution of infective and climatic diseases and to trace the influence of temperature, rainfall, altitude and soil conditions on their prevalence, character and epidemic spread." Under the term "infective diseases" the writer includes "miasmatic diseases, such as malaria; miasmatic contagious maladies, such as cholera; and the contagious diseases proper, such as scarlet fever. Climatic diseases include, amongst others, croup, bronchitis, pneumonia and rheumatism, which are either owing to, or are materially influenced by, meteorological conditions." Organic diseases of the heart, kidneys and nervous system are only noticed in some exceptional cases, where they seem to be influenced by climate. Malarial fevers in their endemic and epidemic forms receive very full attention and their consideration occupies a large portion of the work. Typhoid fever, dysentery, yellow fever, influenza, pneumonia and phthisis are dealt with at length. Only those who have personally worked

in this field of inquiry can adequately realise the immense difficulties which beset the task to which Dr. Davidson has addressed himself, difficulties arising out of scanty, imperfect and often untrustworthy sources of information, different methods of registration, anomalies in medical nomenclature and from other causes. The author says: "To determine the actual prevalence of any given disease over an extensive area with any approach to scientific accuracy is obviously, under present conditions, impossible. The utmost that can be attained is an approximate estimate of the relative prevalence of diseases in different countries. Fortunately," he adds, "such a knowledge as is attainable in regard to most countries is not only full of interest to the student but of vast practical importance to the statesman, the army medical officer and the sanitarian." In some countries, such as Norway and Sweden, all cases of disease which come under the notice of the district medical officers are regularly reported to the State authorities, who publish annual reports, which are accessible. This direct method of ascertaining the prevalence of disease is obviously the best, but it is not always available. The statistician is usually compelled to resort to such indirect methods as (1) the determination of the proportion of deaths from a given disease to a unit of the population, or (2) the proportion of deaths from a given disease to the deaths from all causes within a certain area, or (3) the ratio which each disease bears to the total treated in hospitals, or (4) the reports of physicians who have resided in, or of travellers who have visited, the less civilised countries as to the diseases they have observed to prevail among the natives." Dr. Davidson prefers the first of these indirect methods when available, and adopts it as often as

possible. It detracts from the lucidity and intelligibility of the multitude of statistical tables scattered through this work that first one system is adopted and then another; but this absence of any fixed system is one of the inevitable results of the imperfect character of the available data. The sources from which the author has drawn his information have been "the official returns of the statistical departments wherever these have been attainable. These returns have formed the basis of the accounts given of the pathology of Norway, Sweden, Germany, Austria, Switzerland, Holland, the British Isles, France, Spain, Italy, India, the British Colonies generally and the United States." For the Indian Archipelago, Senegal and Tonkin, the author has depended "on the admirable reports appearing from time to time in the pages of the *Archives de Médecine Navale*." For Borneo, Singapore, Ceylon, Cyprus, Persia, Gibraltar, the West Coast of Africa, the Congo Free State and some other places he has received special reports from medical authorities in the various localities. Dr. Davidson acknowledges his special indebtedness to the great and well-known works of Hirsch, and Lombard.

To review adequately so elaborate and exhaustive a work as the one before us would obviously require more space than we can devote to it. We have carefully studied Dr. Davidson's volumes and we regard them as an important contribution to the study of a vast and complex subject, and likely to fill a useful and honourable place in medical literature. The style is easy and clear, the information is well marshalled, the writer seems laudably free from bias, and the printing and appearance of the work leave nothing to be desired. Nevertheless, the author would probably be the first to admit the imperfections of his work—imperfections which are, to some extent, inherent in the nature of the subject. We are struck by a sense of vagueness and incompleteness in many parts, by the inconclusive character of many of the discussions in which the author engages and by the not infrequent admission of hearsay statements. We admit, however, most fully that the subject is one in which to insist upon a high degree of scientific precision would be simply chimerical. The author has introduced statistical tables when possible. We are surprised that he has made such sparing use of maps. The only principal country thus honoured is India, of which an ordinary school map of no particular value is introduced. We are at a loss to account for this exception, and we think the work loses seriously by the rarity of graphic representations of the prevalence of disease. In discussing such a subject, for example, as the prevalence of malaria in Italy, it seems obvious that a map, coloured so as to show the malarious districts and the varying degrees of virulence of the disease, would be most helpful and valuable. We are struck also in many places by a sense of disproportion in the amount of space and attention given to certain countries and diseases. Thus Great Britain and Ireland receive less space than Mauritius (42 pp. as compared with 58 pp.), a disproportion which is hardly satisfactorily accounted for by the fact that the author has spent a large part of his life in the latter island. We have noticed a few errors in the statistical tables and calculations of averages, but not such as to impair the general accuracy and trustworthiness of the work. We do not care, however, to dwell on small blemishes. If Dr. Davidson has not succeeded in producing a book which can rival, either in exhaustiveness, precision or philosophic temper, the monumental works of Hirsch and Lombard, he has made a very substantial contribution to the study of the geographical distribution of disease, and has produced (so far as we know) the best work on the subject hitherto published in the English language.

Much of the information contained in the work before us is of extreme interest. We find that "the average birth-rate in England and Wales for ten years (1878-87) was 33.5; during the first five years it stood at 34.4, but has lately been

decreasing, for during the last five it had fallen to 32.6. The average death-rate in England during seven years (1881-87) was 19.2, while in the ten years preceding (1871-80) it was 21.4. The death-rate is thus diminishing and is lower than that of any European country, except Ireland, Norway, Sweden and Denmark." We find that malaria, once so common and fatal in England, is now steadily dying out. The deaths from this cause have fallen from 8.2 per 1,000,000 living in 1841 to 3.2 in 1885. The most malarious parts of England are Bedfordshire, Kent and Huntingdon; the least, Rutlandshire, Westmoreland, and Oxfordshire. The improvement is due to better drainage and improved methods of cultivation. It is very satisfactory to find that England also shows a steadily diminishing mortality from enteric fever. The death-rate per 1,000,000 living from this cause, which was 373.8 in the five years (1871-75), had fallen to 277.2 in the succeeding five years, and to 215 in 1881-85. The investigations of Dr. Davidson tend to show that enteric fever is most prevalent in seasons when the mean annual temperature is above the average, and the temperature of the third quarter of the year especially so. He has been unable to trace any connexion between the prevalence of enteric fever and rainfall. Diphtheria appears to be increasing in England, the average death-rate from this cause, having risen from 121.3 per 1,000,000 living in the decennium 1871-80 to 155.6 in the five years 1881-85. Phthisis shows a marked and steady decline. The deaths from this cause per 1,000,000 living, which were 2526.6 in 1861-65, had fallen to 2218 in 1871-75, and to 1820.6 in 1881-85. Dr. Davidson agrees with most inquirers in attributing the prevalence of this affection partly to the character of the soil and partly to the occupations of the people. Cancer, as is well known, is increasing in these islands. "The disease is not observed to follow the course of rivers or to be affected by geological formation; it affects indifferently the poor and the rich, and occurs with equal frequency in agricultural and industrial districts."

Dr. Davidson devotes 164 pages to the interesting subject of the distribution of disease in India, and gives us one of the best accounts of the question which have appeared. Naturally, the consideration of the various forms of fever occupy most of his space. "Throughout the whole of India," he informs us, "there is no province or extensive district entirely free from malarious disease." In the year 1883, out of 5,595,648 deaths in India from all causes, 2,883,101, or more than one-half, are ascribed to fever. Malaria is most prevalent in the North-west provinces and Oudh; the Punjab comes next; Bombay, the Central Provinces and Berar are also much affected; while Calcutta, Madras and Mysore show a relatively low mortality from malaria. The forms of malarial fever in India are the intermittent, the remittent and the continued. "Among the natives the intermittent is by far the most common, but the remittent is by far the most fatal. Among the European troops the continued form is the most common." Intermittent fever is an autumnal disease on the Indian plains. In some of the hill stations a spring rise is found. The prevalence of the disease is in proportion to the mean temperature of the summer months. The influence of rainfall is more complex. It would appear that the important point is not so much the amount of rain as the nature of the soil and the facilities for drainage. "The evil effects of water-logging of the soil," says Dr. Davidson, "whether brought about through irrigation or inundation or by excess of rainfall, is a point past dispute. It must be counted a potent factor in increasing malarial prevalence." In many parts of India there is an apparent inverse ratio between fever prevalence and fatality and dysentery prevalence and fatality; but there are exceptions to this rule.

As regards the disputed point of the prevalence and frequency of enteric fever in India, Dr. Davidson says that

"enteric fever was formerly regarded as exceedingly rare in India, although it is now recognised as one of the most fatal diseases of the young European soldier during the earlier years of his sojourn in India. It is generally held up to the present time that the disease is rare among the natives of India; but," he adds, "it will probably be found that it is not so rare among the natives of India as is generally supposed, although it is undoubtedly much less frequently met with among them than among the newly arrived Europeans." Military statistics show that enteric fever causes ten times as many deaths among the soldiers in India as in England. No less than 65·2 per cent. of the admissions occur in soldiers who have had less than two years' service. Many Indian authorities incline to the view that the disease often arises independently of any specific infection. A very full account is given of cholera, but into this subject we cannot enter. Hepatitis is one of the most fatal diseases of the English soldier in India. In 1883 the death-rate from this cause in the British force was 1·13 per 1000, while in the native army it was only 0·18 per 1000. The difference, according to Dr. Davidson, is due to the freer use of spirituous liquors by the European soldier. Hepatitis is most fatal in the Madras presidency, where malarious diseases are least frequent. Leprosy is endemic in India. The proportion of lepers is 57·3 per 100,000 of the population. Berar is the province in which leprosy is most prevalent. It is also common in Bengal, in the Punjab, in the Central Provinces, and in Assam and Burmah, while it is comparatively infrequent in Ajmere, Mysore, Gujerat, Chittagong &c. "All the facts," according to Dr. Davidson, "seem to point to heredity or contagion as the means of its spread and the cause of its persistence in any given locality," while the evidence "lends no support to the view that it is caused by a fish diet."

We might enter into many other interesting questions which the perusal of these volumes naturally suggests, but our space is exhausted and we must rest content with what has been already said. The study of the geographical distribution of disease is likely to throw much light on many interesting and difficult questions. To that study Dr. Davidson's work is an important contribution.

*Annali delle Epidemie occorse in Italia dalle prime memorie fino al 1850.* Scritti da ALFONSO CORRADI, Dottore onor. dell' Università di Cambridge &c. Vol. VII. Appendice. Parte 1 e 2. 4to, pp. 1265. Bologna: 1892.

THESE two goodly quartos, containing together 1265 pages, are the supplement to Professor Corradi's previous six volumes, the first of which appeared in 1865, and are the completion of his great undertaking, all but a volume of indices and tables which is now in the press. The profession of medicine may well be proud of this achievement. The work has been designed on a scale which we are apt to think belongs only to the old days of erudition—to the age of folios and quartos; and it has been executed in the most workmanlike fashion, without diffuseness or unnecessary discursiveness, with economy of space in the use of various sizes of type and in the remarkably uniform system of citing authorities, and (so far as we have observed) with strict relevancy and point in the critical comments. From the nature of the subject this immense work has been a labour of love, made possible by the author's occupancy of a chair at Pavia and by the liberality of the Medico-Chirurgical Society of Bologna in bearing the expense of publication. No other country but Italy could have yielded the same abundance of materials to work upon, and it is in keeping with the old repute of the Italian universities and learned academies that the copious historical records should have been so thoroughly and correctly handled. With Professor Corradi's monumental book to point to, no one can say that the old spirit is extinct. Utility, or immediate

profit, may appear at times to bear down everything else or to do so in one country more than another; but there is as much learned curiosity as ever there was and a far more perfect apparatus for gratifying it.

The two quartos before us, making the seventh volume of the *Annals of Epidemics in Italy*, consist partly of matter which had been inevitably overlooked in the long series of years dealt with, partly of information which has been brought to light since the work began in the numerous recent researches of Italian antiquaries and historians. Nearly the whole of the supplementary matter belongs to the period subsequent to the arrival of the Black Death (1347-48), only some sixty pages being occupied with new facts from the earliest mediæval period or the period of antiquity. The principal supplement, occupying 1014 pages, covers the whole period to the year 1850 for the second time, and might pass for a tolerably full series of annals if there had been no six volumes already published. But new matter was still accumulating while the supplement was under hand, so that the chronology had to be gone over for the third time in 246 pages more. It is clear that the author could never have found a place for all his original facts, and for these successive additions to them, had he not designed his work under the form of annals. Under each year are chronicled events of more or less importance, at more or less length, with or without critical remarks or discussions. This is, of course, the method of Dr. Dryasdust, as if, to use Carlyle's illustration, the space for each year of the chronology bore the superscription "Dry rubbish may be shot here." But it is all a matter of taste whether such collections, methodically arranged, including often the full text of historical records, are to be accounted dry or of the nature of rubbish. The annalistic method offers many advantages in the way of fulness and precision of statement; and it may be safely affirmed that Professor Corradi could not have produced so serviceable a work if he had followed the plan of a consecutive digested story of the various types of epidemic sickness in the several provinces of Italy from the earliest times. What happens under the annalistic treatment is that certain years afford the opportunity for considerable chapters of history: such years, for example, as 1348, when the Black Death comes up; or the year 1494, when syphilis broke out; or 1528, when the French army was in Italy and the whole country was full of typhus fever; or 1557-8, when there was influenza; or 1576, when many of the Italian cities were desolated by plague. The supplementary matter alone under 1576 occupies no fewer than forty-eight pages of small type. Again, under the year 1471, we find the full text of a Modena plague-bill for that year; and under 1448 there is a comparison, in parallel columns, of the teaching of two early treatises on plague, one by Pietro da Tussignano, who died in 1403, and the other by Saladino Ferro about 1448, the problems of contagion, of incidence, of favouring conditions &c., discussed in these mediæval writings being curiously like those which interest ourselves. In his second supplement, under the year 1348, the author adduces some further evidence concerning Gabriel de Mussis, whose manuscript on the outbreak of the Black Death at the siege of Caffa in the Crimea, discovered at Breslau in 1842, has been made of primary importance, inasmuch as he claims to have seen the first of that great epidemic with his own eyes. The new evidence tends to show that De Mussis was practising the law at Piacenza all the time, so that he may have got his information merely at second-hand from some one who had returned from the East.

These are examples of the immense variety of interesting and important points dealt with by the author as they arise under the respective years. The forthcoming volume of indices will be indispensable. The promised indices or tables are ten in number: (1) Index of authors and works cited; (2) topography of the epidemics; (3) chronology of the epidemics; (4) table of dates with localities; (5) military

and naval epidemics; (6) epizootics; (7) principal meteorological phenomena; (8) other public calamities; (9) occasions of public assistance—distribution of food, medical aid, &c.; (10) index of all other notable things. It will be seen from this enumeration that the annals record all the events that may have had any relation to epidemics—earthquakes, volcanic eruptions, floods, droughts, famines, as well as the various murrains. The information from the several provinces and cities of Italy is so full that calamities of all kinds, from influenza to plague, seem to follow each other with bewildering frequency. So many famous cities of Lombardy, Venetia, Tuscany and the other Italian States had a vigorous civic life at so early a period that their chronicles are more fully written or better preserved than is the case with regard to the rest of Europe. Italy was a century or two ahead in such matters, as well as in specially medical writings like the classical work of Fracastori on Contagion. For these and other reasons the annals of epidemics in Italy afford unequalled opportunities to the epidemiologist. Professor Corradi's task has been exacting in proportion, and has been executed with scrupulous fidelity. It would be interesting to know in what way so much erudition acquired throughout a lifetime had coloured his views of contemporary doctrines and controversies. At the end of his work he permits himself four pages of epilogue in which he indicates, not without eloquence, the bearings of epidemiological study. Among other points we observe that he appears to assign a somewhat inferior part to specific living organisms in the production of specific infections. He appears to refuse altogether the high parasitic doctrine: "La storia delle grandi epidemie di *tifo*, e in particolare le navali e le castrensi, si oppongono a si recisa sentenza."

### THE CONTAGIOUS DISEASES ACTS.

In the current number of a monthly journal there appears a letter from a correspondent on "The Solidarity of Vicious Methods." In it the probability of the Contagious Diseases Acts being restored is pointed to, and the various individuals living and dead, together with the medical and lay papers which have defended these Acts and deprecated their repeal, are held up to public ignominy. The late Mr. J. Fenimore Cooper, the American novelist, warned the critics, in his preface to "The Pilot," that as a sailor he possessed the privilege of including them all under the sweeping title of "lubbers." Similarly we might regard the writers of those many articles and letters which have appeared in the lay press denouncing us and our advocacy of these Acts as ignoramuses and treat their foolish effusions with silent contempt. We prefer, however, to adopt a more courteous tone and at least to endeavour to show these writers their errors. The letter before us places us in doubt as to whether the writer belongs to the sterner or the weaker sex. In the second sentence of the letter the repealed Acts are termed the "ghastly State regulation of prostitution." It has been shown over and over again that the State never proposed or attempted to regulate prostitution, but to prevent certain contagious diseases at certain military and naval stations. This jumbling together of vice and disease is a favourite device of the opponents of these Acts, since it has the effect of securing the support of that large number of members of both sexes who possess neither logical reasoning powers nor lucidity of argument. Men and women of the world who do possess these know that vice and disease are not necessarily cause and effect. A man who keeps a mistress is quite as vicious or immoral as a man who resorts to a prostitute, yet the former may commit deliberate fornication with impunity for a lifetime, while the man who yields to the wiles of a prostitute may contract a disease which will infect his constitution for years. If he be a married man he may infect his wife and unborn child; if a single man he ought to be warned against marrying for years to come; and in either case much annoyance and suffering are involved. Again, infection with

venereal disease is governed by certain circumstances which this confusion of terms wholly ignores. Some individuals of either sex are from natural conformation peculiarly liable to contract disease; others are not. The influence of circumstance as a factor in preventing infection is well known to those practitioners who treat venereal diseases. Hence the contention that venereal diseases are a heaven-sent punishment to vicious persons is not true. The Acts were applied to a very limited area, the localities in England being Aldershot, Canterbury, Chatham, Colchester, Dartmouth, Deal, Devonport, Dover, Folkestone, Gravesend, Maidstone, Plymouth, Portsmouth, Sheerness, Shorncliffe, Southampton, Walmer, Winchester, Windsor and Woolwich. In Ireland the operation of the Acts was limited to The Curragh, Cork and Queenstown. Now, if the effects of the Acts were so vicious as their opponents contend, we should have had both negative and positive evidence of this. The places just named would, during the application of the Acts, have been remarkable for an increase of flaunting vice; while the localities not subject to them would have presented a marked contrast in this respect. But what are the facts? The evidence of perfectly independent and thoroughly unbiased witnesses given before the Royal Commission and the Lords and Commons' Committees was that the effect of the Acts in reducing the number of prostitutes and in promoting better order in all the districts subjected to them was most marked. On the other hand, the condition of London and the other large towns and cities in England and Ireland to which these Acts have never been applied has altered but little as regards prostitution within the twenty-eight years which have elapsed since the first Act of 1864 was passed. Moreover, since the Acts were repealed the towns formerly subjected to them have not improved. On the contrary, so greatly has prostitution increased, and particularly in its worst form of juvenile prostitution, that the local authorities would welcome the re-enactment of these Acts. Turning again to the letter we find that THE LANCET is abused for its article of Jan. 23rd "praising the moral effects of the Acts, and speaking of their opponents as though they were enemies of morality and mercy." Various other journals, both professional and lay, come in for severe reprehension for defending these Acts. THE LANCET being alluded to no less than five times in the course of the letter, we may briefly recapitulate our reasons for the course adopted in these columns with reference to this legislation. We maintain that it made an attempt to deal with what religion and philanthropy had failed to do—the social evil in its worst aspects. What notice had been taken of the wretched women in Portsmouth and Plymouth, in Chatham and Windsor, in Cork and The Curragh? What attempt had been made either to cure their diseases or to attempt their moral reclamation? Either nothing at all or so little that it had not even scratched the surface of this great evil. By means of the Acts these women were brought under the kindly notice of the visiting and hospital surgeons, who examined them with every regard to their feelings and ministered to them in hospital until they were cured. Being gradually humanised, they became in a better condition to become reformed. By the kindly assistance of the chaplains, and matrons, supplementing the work already begun by the surgeons, these women in numerous instances forsook their previous wretched life and eagerly embraced the facilities afforded them of commencing a better one. All these are facts which cannot be disputed or denied, and so the term "State-regulated prostitution" simply recoils on those who use it, not from knowledge, but from ignorance of these Acts and their working. These diseases are acquired not from sin merely, but from sin committed with a diseased person. Those who are really virtuous and wish to remain so can do this whether the Acts are in force or not. No man or woman need sin against his or her will. For all these reasons we shall continue to support these Acts and to urge their restoration, amended as circumstances may require, to the statute-book of this country.

**PROPOSED ISOLATION HOSPITALS.**—At a meeting of the Epsom Local Board last week it was resolved that a permanent isolation hospital be built on land belonging to the Board at Kingston-lane, and that application be made to the Local Government Board to sanction a loan of £1000 for that purpose. The rural sanitary authority of Redruth is making arrangements for the erection of a hospital for the isolation of patients suffering from infectious diseases.

# THE LANCET.

LONDON: SATURDAY, SEPTEMBER 24, 1892.

IT is easy to be critical or even cynical over the instructions of the Royal College of Physicians for the treatment of "patients suffering from cholera, choleraic diarrhoea or diarrhoea"; but admitting, for the sake of argument, that the College was obliged to formulate some instructions (and as we said last week they appear to us to be plain and practical and in accordance with the line which we ourselves recommended to be adopted by the profession) we do not see that it could very well have done better than it has done. This is, however, a considerable admission. The College might have taken different ground and given different advice. We are disposed to think that it would have acted wisely in doing so. The Royal College of Physicians is a representative and responsible body. It is not entitled at a great crisis of national sickness to withhold its sympathy and its help from the people. When called on by the Local Government Board, representing the State, for its contribution of wisdom and counsel, it is under a very grave obligation to do its best. It must be admitted further that there is precedent for going into detailed prescriptions, though scarcely, perhaps, in such detail as in the suggestions just issued by the College. We have before us a report of the action of the College in similar circumstances in 1866. On that occasion the College was set in motion by the Lords of Her Majesty's Privy Council, as represented by their distinguished medical officer, Mr. (now Sir JOHN) SIMON. Sir JOHN SIMON'S request was limited and modest as compared with that of the President of the Local Government Board. It simply raised the question of the expediency of issuing instructions to *captains of merchant vessels* as to how they should act when proper medical attendance could not be procured so as to provide for the health of their crews against attacks of cholera. Their lordships wished particularly for the suggestions of the College—first, as to the necessity of avoiding purgative medicines, and, secondly, as to the measures to be adopted when cholera appeared on board ship. On the present occasion the Local Government Board propose to issue Regulations for the guidance of local sanitary authorities, requiring them, amongst other things, to provide and dispense without charge medicines and medical appliances for the sick, and they apply to the College for instructions and prescriptions, with the flattering remark that they believe the local authorities will attach great value to the medicines which the Royal College of Physicians consider best adapted to patients suffering from cholera, choleraic diarrhoea or diarrhoea. This is a much larger request than that of the Privy Council in 1866, and one which involves much more serious consideration. The reply of the College is perhaps a very natural one, and, as we have said, if it had to undertake instructions and prescriptions could not well be better. The instructions for the maintenance of general health indeed suggest that they were framed by practitioners who cater for that section of the community who command any number of meals they please, of any quality, including choice wines, and who are equally

able to select model houses for residence, with drainage and all appurtenances complete, rather than for the poor. The prescriptions are as good as general prescriptions for individual cases could be and fairly represent present therapeutic views as to the best measures to be taken for the prevention of cholera in cases of diarrhoea. We even admire the ingenuity with which the advocates of rival methods of treatment are conciliated, and with which the general indications of experience and common sense are respected. It is refreshing to see the ancient College alive to the virtues of coto, which has as yet no place in our pharmacopœia, and which, it may safely be assumed, is still an unknown drug to many chemists and even too many Fellows of the College. There are also cognisant of the still more recently discovered powers of enemata of tannin, of which a very interesting account will be found in THE LANCET of last week, p. 682. But the question still remains whether it is a dignified position in which to place the College of Physicians to ask it to be a party to, the preparation of two or three huge bottles or reservoirs of medicine out of which practically the whole community is to be doctored. There is no disease which can be treated with advantage in such a general fashion, and cholera especially defies all routine prescriptions. It may seem very natural to some minds that the State should undertake a general treatment of the cholera of the community, and that "without charge." The ease and cheapness of the scheme are fascinating, and so is the idea of bringing the humblest citizen into the advantage of being prescribed for by the College of Physicians. Still we gravely question the advantage. It is the undoubted duty of the Local Government Board to see that the poorest section of the community in the remotest parts is medically provided for at all times, and especially in times of great and urgent sickness. But it cannot discharge its responsibility by applying for a few prescriptions to the College of Physicians, to be dispensed mechanically for cases and in circumstances which the College never contemplated. The only efficient way in which the Local Government Board can secure medical aid to the poor is to use its influence over local sanitary authorities in the direction of perfecting the arrangements for procuring easy and early medical and nursing attendance. These arrangements should include provision for house-to-house visitation in poor neighbourhoods under any suspicion of harbouring the disease or the conditions favourable to it. What is wanted is not so much physic as physicians who can attend promptly to individual cases and give them the particular treatment which each case requires. We are confident that in this view we shall have the concurrence of the College itself. It is not only that general instructions applied in a routine way cannot be relied on, but the tendency of such action on the part of the College is to diminish individual earnestness and the sense of individual responsibility. The function of a College of Physicians is to qualify men to treat disease and then to throw the responsibility for its treatment on them—not to supply chemists and medical men with ready-made prescriptions. This is the way to hinder therapeutics rather than to help it. So much as regards even the poor. It is essential to supply them not so much with medicine as with medical men. One way in which the Local Government Board can best effect this supply without undue strain on the local authorities is to restrict it to the poor. We seem to see in the letter of Sir

HUGH OWEN an intention to take the whole community in hand and to cater for those who have their own doctors and the means of paying them—"to provide and to dispense, *without charge*, medicines and medical appliances for the sick." This is a large order, for which we see no need or justification. The addition of one word will remove all objection to the sentence as it now stands. But this addition is essential if such schemes are not to be demoralising. Instead of sick read "sick poor," and in addition to medicines and medical appliances say "and medical men," and all will concur in the enlightened and benevolent energy of the Local Government Board.

THE conditions under which clothing is made are at the present time exciting unusual interest, because it has been alleged that a member of the Royal Family has been exposed to risk of infection from circumstances which, in the tailor's trade, lead to clothes being made in the homes of the workers. It does not appear from the published statements that there was more than possibility of danger; it is not alleged that the clothes of this distinguished person were actually made in a room occupied by a case of infectious disease, but the reader is left to infer that what is possible for a prince is a matter of daily occurrence for those less highly placed, and that there is for the community at large a very palpable danger of infectious disease spreading from the tailor's workshop or the homes of his *employés*.

The channels by which diseases of this class may be conveyed from the sick to the healthy are so numerous that it is impossible to ensure with any certainty that any person, however well circumstanced, shall be entirely free from all risk. That every care should be taken to lessen the chances of accident will not be disputed; but in considering what is practicable, it is necessary to remember that the workers are unable to guard themselves against disease and that the public cannot insist on the adoption of more than reasonable precautions. The lesson that has to be learnt is that we are all members of one family and that it is only by safeguarding the poorer members against maladies to which all are liable that the richer can hope to secure their own protection.

We may recall with satisfaction the fact that as long ago as the year 1884 THE LANCET appointed a Commission to inquire into the condition of Jewish tailors in the East-end of London, mostly foreigners, the greater number of whom were Poles. Our Commissioners found them working in unwholesome, overcrowded houses, where girls and women were kept employed long after the hours prescribed by the Factory and Workshops Act. Such people were wanting in even the more elementary habits of cleanliness which are possessed by the poorest of English people. These aliens arrive in England usually entirely ignorant of the language, and become the slaves of those who choose to employ them for the most scanty remuneration. The insanitary conditions under which work was done showed that there was open defiance of the Factory and Sanitary Acts. It was, indeed, matter of great difficulty to get reliable information regarding the relations in which the workers stood to their employers and to each other, for upon the appearance of a stranger steps were immediately taken to mislead. The women and children were scattered all over the house, and if questioned the answer came readily that one was a niece, another a daughter and so on. It is not matter for surprise

that these poor people could know nothing of the dangers, to themselves or to those who wore the clothes they made, of infection from a case of fever or small-pox in their family.

Later, extending our investigations to Manchester, Liverpool and Birmingham, as well as to Glasgow and Edinburgh, we found that in these towns much the same conditions existed. The subdivision of work led to insufficient feeding, overcrowding and overwork; the poorest classes were employed at the smallest remuneration for work made under conditions which rendered the workers liable to disease which might readily be conveyed eventually to the wearers of the clothing. Undoubtedly some improvements have been effected since that time, and the necessity for more detailed inspection of the places in which work is done has been recognised, for it has led the Legislature to place the supervision of workshops and workplaces entirely under the control of sanitary authorities, with the additional precaution that in the event of these bodies being found to be negligent the Secretary of State has reserved to himself the power to send, to use Mr. MATTHEWS' expression, "an army of inspectors" to carry out the law.

It is too soon to judge of the result of this legislation. The sanitary authorities will now be held to be responsible not only for the condition of the places in which the workers dwell, but of those in which they are employed, and this latter in relation to the subject which we are now discussing is not the least important matter. It may be hoped that the object of this change in the administration will not be lost sight of. For any effectual protection of the public the staff of sanitary officials must be largely increased, and if the public require protection from dangers which have lately attained exceptional prominence, they must not begrudge the cost of the administration. Precautions such as those we indicate are in every sense reasonable; they are such as everyone has a right to expect; for while the well-to-do may, when paying a higher price for their clothing, demand that work shall be done on the premises of the master tailor, the multitude must rely for their own safety upon that more general protection against disease which the enforcement of the provisions of the Public Health Acts is capable of affording.

AMONG the COKE MSS. in the possession of Earl COWPER at Melbourne Hall are several letters from ANNE, Countess Dowager of ARUNDEL, to her son, the famous Earl THOMAS (who collected the Arundel Marbles), relating, among other things, to his children, who appear to have been mostly left in charge of their grandmother, sometimes at Arundel House in London, sometimes at Sutton, a country house on the north bank of the Wey, about three miles north-east of Guildford and three miles south of Woking. The Manor of Sutton in Woking belonged to the family of WESTON, one of whom (Sir HENRY, who died in 1592) had married a daughter of Sir THOMAS ARUNDEL of Wardour, her mother having been a HOWARD of Arundel. Perhaps that is how we should explain the fact of Lord ARUNDEL'S children residing at Sutton, near Guildford, with their grandmother. Several of these letters belong to the winter of 1613-14, when the Earl and Countess were in Italy; they contain various references to the health of the three boys, which need not detain us. It is in the following two letters, undated, but belonging to the month of

February, 1619 (not "about 1616," as the editor of them for the Historical Manuscript Commission says conjecturally), that HARVEY is introduced to us as a consulting physician. The fourth surviving child, CHARLES HOWARD, who was born subsequently to 1614, fell ill suddenly; whereupon his grandmother despatched a messenger to the Earl to "send with speed the best doctor may be had." The doctor sent was HARVEY, who would doubtless have ridden down from London, a distance of some twenty-five miles, crossing the Thames probably at Kingston. Whether he arrived in time to see the child alive does not appear clearly from the second of the two letters. He met Mr. RAYNER of Guildford in consultation, and it is pleasing to note that he took the same view of the case as that practitioner. He was to stay the night at Sutton, and it was hoped, when the messenger was despatched late on Saturday, that Dr. HARVEY would be stirring early next morning, so as to ascertain "the true inward occasion"—i.e., make a post-mortem examination. The first letter, dated "Sutton," is printed as follows in the Calendar of the COWPER MSS. :—

"Presently after the despatch of my footman we found that Charles was not after his usual sort, refusing breakfast. .... bath took nothing, but tossed and drank sometime in the night. .... His wind very short, and his pulse and heart worketh so extremely fast as I never knew the like .... I assure, sweetheart, the poor child is exceeding evil. I beseech you send with speed the best doctor may be had. I fear the child very much. God bless him and you all."

The next letter is dated

"Sutton, Satr. late.

"MY GOOD SONNE—About two houres after my servant's departure towards yr Lo. this morning the poore child continuing very sicke hee cast twice a littell quantity of darke tawny color. Some time after, being then about noon, he cast a good quantity together of black color, which did offer some time to come in littell quantity so long as he had life. It pleased our blessed Savyour to take him to himselfe something before 4 a clocke this after none, having suffered very sharp pains befor his ende. Mr. Doctor Harvy is of the same opinion that my Gilford neighbour Mr. Raner was to day when he did purseve what he did avoyde, which is, that some continued impostum caused his ende. I trust Mr. Doctore will so early be sturing as Mr. Ardern shalbe able to lett yr Lo. bee satisfied of the inward true occasion, and I beseech you for godsake to comforte your selfe and my good sweet daughter with the true good of the sweet soule of your littell sonne, for I am sure wee should all have hartily rejoyced if it had pleased God to have sent him health and strength of body....

"I ever rest, your Lo. faithfull loving Mother,

"ANNE ARUNDELL."

Any glimpse of HARVEY is of interest; and the fact that he was employed by the Earl of ARUNDEL as early as 1619 is of some importance. It was through Lord ARUNDEL that HARVEY came to make the anatomical examination of old PARR, in November, 1635, his lordship having brought that aged person from Salop to London, kept him in his own house, and presented him to the King as a wonder. Next year (1636) HARVEY accompanied Lord ARUNDEL as his physician, in the embassy to the Emperor to settle the affairs of the Palatinate. But, in the above letters, we have clear evidence of his attending the HOWARD family at a much earlier period of his London career. The letters are undated, but the incident to which they relate, the death of the youngest boy, CHARLES HOWARD, is known to have been in February, 1619. HARVEY had already been ten years

physician to St. Bartholomew's Hospital. The only ambiguity relates to the place called "Sutton." There were two Suttons near Guildford—Sutton House, which was the original manor house, and has long since disappeared, and Sutton Place, which was built for the WESTONS, a fine quadrangular edifice of HENRY VIII.'s time, entered by a great gateway flanked by towers, with a gallery in which Queen ELIZABETH was entertained, and a hall of spacious proportions. It is still there, all but the fourth side with the gateway, forming one of the architectural sights of the county of Surrey. It seems probable that this was the Sutton from which the Dowager Countess dated her letters: it belonged to the WESTONS, a Catholic family connected by marriage with the HOWARDS; it had a chapel in which Mass continued to be said without interruption from pre-Reformation times; and Father WILLIAM WESTON, a leading recusant priest, was the Dowager Countess's spiritual director. Her son, Earl THOMAS, had conformed to the Anglican rite, but he seems to have left his children to be brought up as Roman Catholics by their grandmother. In 1857 the Duke of NORFOLK printed from a family MS. a life of that pious and exemplary lady, along with a life of her husband, Earl PHILIP. The incident of the boy's death, as above, is brought in to show her religious resignation; but beyond stating that the child was four or five years old and that his education had been wholly remitted to his grandmother, the Life throws no further light on the event, and does not mention where it happened. Five years later, in 1624, the Dowager Countess was living at "her house at West Horsley," which is in the same neighbourhood, "her house" having been probably the still existing JAMES I. mansion there. She was of considerable wealth, and left money to found a college at Ghent. We shall probably not err in assuming that, in 1619, she was occupying Sutton Place, or perhaps one wing of it. If that be so, we can still point to a country mansion where HARVEY is known to have been called in consultation from London, where also he is known to have expressed his agreement with the local practitioner in the judicious diagnosis of a "continued impostum,"—probably peritonitis, and perhaps intussusception.

## Annotations.

"Ne quid nimis."

### THE PHYSICIAN'S INFLUENCE IN DIPLOMACY.

COMPILERS of social and political anecdote might put together an interesting and instructive volume on the share physicians have had in moulding the opinions and determining the policy of monarchs or statesmen or diplomatists to whom they were professionally attached. The published biographies of men high in official position teem with acknowledgments of what they have owed to their medical advisers, not in the matters of health only, but in the sphere of Statecraft. One of these which saw the light not so long ago—the charming "Memoirs of an ex-Minister"—contains a memorable passage in point. Lord Malmesbury, the Minister for Foreign Affairs under the Derby-Disraeli Administration, and the author of the memoirs referred to, makes particular mention of the professional visits of Dr. Fergusson—the Robert Fergusson who figures so honourably in two such diverse books as

Watson's "Practice of Physic" and Lockhart's "Life of Scott." His lordship had asked the doctor's opinion on the state of parties and the political outlook of the day, and, having got it, adds: "I fear he is right" [as undoubtedly he was], "for," proceeds Lord Malmesbury, "nobody is a better judge of public feeling than a doctor, who is constantly seeing all kinds of people." Another illustration, of a more dramatic though of a less satisfactory nature, meets us for the first time in a similar book just published, "The Diplomatic Reminiscences of Lord Augustus Loftus, P.C., G.C.B., 1837-1862." The Emperor Alexander of Russia, brother of the Czar Nicholas, inherited a good deal of the eccentric character of their common father, Paul, whose assassination is one of the most tragic incidents in the sombre page of Russian history. Alexander, it appears, had been privately informed of a conspiracy to take his life, and, acting on the information, had altered the route. He was then passing between Moscow and St. Petersburg. By shaping his journey homeward *via* Taganrog to the south he hoped to defeat the purpose of the conspirators. At that remote town he fell ill of "bilious fever," and in his suspicious frame of mind nothing would induce him to follow the advice of his excellent body physician, Dr. Wyllie. The doctor was reinforced by the entreaties of the Empress, but in vain. Alexander, seeming to court death, ordered a priest to be sent for, and meantime Dr. Wyllie and the Empress renewed their importunities to get him to take the remedy prescribed. This he finally agreed to do, and with the arrival of the priest renewed pressure was put upon him not to commit suicide by refusing the medicine. The priest, in fact, declined to do his part until the imperial patient acted on Dr. Wyllie's orders. To relieve local congestion leeches were applied to the head, and, after a time, the Emperor, sending for his consort and Dr. Wyllie, asked them if they were satisfied. They replied they were (for the time, at least); whereupon he tore off the leeches and by preventing their action seriously compromised his chances of recovery. The disease, in spite of the physician's efforts, had to run its course and the imperial patient died. Other anecdotes of Dr. Wyllie's association with the *via intime* of the Russian court represent him in a more successful light, extra-professionally as well as in his medical capacity, and must, if collected, form a favourable specimen of the volume we have suggested to the compiler—a volume which might have many an interesting counterpart drawn from the experience of others of his compatriots in their rôle as consultants to kings and their ministers.

#### HAMBURG WATER.

THE results furnished by a chemical analysis of the water supplied to Hamburg admit of but one interpretation—the water is highly polluted, and it has thus no doubt afforded an excellent channel for the distribution of the disease which is causing sad havoc in the city at the present time. A sample of water taken from the mains by an ordinary tap, just as it is supplied for drinking purposes to the houses, was recently procured by Mr. J. B. Coppock, F.C.S., who submitted it to analysis, the details of which appear in the current number of the *Chemical News*. The water is described as turbid and very yellow in appearance, as slightly unpleasant to the taste, as possessing little odour and containing a small and dirty-looking deposit. Microscopic examination revealed animal and vegetable matters as well as mineral particles. The total solids amounted to 81.25 grains, the chlorine to 33.04 grains, the free ammonia to 0.0746 grain, the albuminoid ammonia to 0.0205 grain, the sulphates to 2.37 grains, and the nitrates to 1.95 grain per gallon. Oxygen consumed in fifteen minutes was equal to 0.065 grain, and in four hours to 0.24 grain per gallon. The most striking item is perhaps the chlorine. It occurs to an enormous extent and may have been derived from the chlorides in animal evacua-

tions, as in urine, although on the other hand there is no evidence that it is not of mineral origin. The nitrates do not appear to have been estimated, neither are any observations recorded as to the behaviour of the solid matter on heating. This is regrettable, we think, as the presence of nitrites affords fair proof of the existence of putrefactive matter still undergoing oxidation, while the character of the odour evolved on heating the solid matter frequently indicates whether the contamination is of vegetable or animal origin. Cultivation in nutrient gelatine produced an abundant crop of bacteria—bacilli, micrococci and fungi—but the consumption of the water, Mr. Coppock adds, has not produced any choleraic symptoms in the case of a cat. The water-supply of Hamburg is drawn from the River Elbe. London, he it remarked, also derives her water-supply mainly from a river, and although that river has hitherto yielded water of surprising purity after suitable treatment, yet in view of the present enormous rate of increase in the population not only is this source of supply likely to prove inefficient within a few years, but, what is still worse, it will probably become less pure, in consequence of the increasing demands made upon an already overtaxed river by the present system of sewage disposal. A consideration of these facts, especially at this time, should lend fresh impetus to the labours of the Royal Commission, which will shortly resume its sittings.

#### MIND-BLINDNESS.

IN the last number of the *Neurologisches Centralblatt* appears an abstract of a paper by Dr. Wilbrand, in the *Deutsche Zeitschrift für Nervenheilkunde*. In this paper is given the sequel to a case of mind-blindness with hemianopia, published by the author in 1887. The completeness with which the case was recorded in the first instance and the accuracy with which it was observed give the highest value to the account which is now presented of the condition of the brain. The patient was a woman, aged sixty-three, who until the onset of her illness had been healthy and intelligent. She suddenly became unconscious, and for some weeks she remained so. When she regained consciousness she mistook animals for human beings, and her ideas as to her position in time and place were rather hazy. Even in well-known places, such as her own house and amidst her own furniture, she could not find her way about; but if she closed her eyes her power of regulating her movements was much greater. She was confused and excitable; she said that she thought "upside down," that she lead "a mechanical life," and that her sense of smell was much finer than usual. She also suffered from feelings of "explosions," which took place in her head without any noise, but accompanied by a sudden perception of light. There was no paralysis of ocular muscles and no change in the fundi; there was incomplete left homonymous hemianopia and a partial hemianopic defect in the lower half of both right fields. Inside the defective left half-fields there was a zone in which only light—not form or colour—was recognised. She read writing and printing fluently with the aid of convex glasses. She could write to dictation correctly, but in spontaneous writing she made frequent mistakes, omitting words or repeating them needlessly. Her symptoms varied but little during ten years, and she finally succumbed to an apoplectic attack within a few hours of its onset. At the necropsy the fusiform lobe on the right side was found to be depressed, and it had apparently been transformed into a loose-walled cavity which extended to the extremity of the occipital lobe. The occipital convolutions were reduced in size; the whole lobe was somewhat depressed but not softened. The hinder part of the cuneus was softened, its extremity being connected with the softened area of the fusiform lobe. The cortex of the calcarine fissure was a little altered; the precuneus was normal and so were the lateral aspects of the occipital lobe and of

the whole parietal region. On the left side there was a small cavity under the grey matter of the second occipital convolution, with a softened area in front of it, evidently an old lesion, and anteriorly this was continuous with a recent softening which had completely destroyed all the central matter of the hemisphere. It will thus be seen that the centre for the reception of visual impressions in the left hemisphere was intact, but the interruption of the subcortical associational fibres had resulted in permanent mind-blindness. On the other hand, by the destruction of the cuneus and the affection of the calcarine fissure on the right side, the function of the centre for the reception of visual impressions on that side was abolished, and as with closed eyes the recollection was scarcely impaired the symptoms of mind-blindness must be wholly ascribed to the lesion in the second left occipital convolution. The total blindness which was present at the commencement of the illness is to be ascribed to the permanent destruction of the area for visual perception on the right side and to a temporary abolition of the function of that on the left side through pressure on the fibres, which had not caused complete destruction. Dr. Wilbrand had previously suggested that mind-blindness was the result of a cortical lesion in an area in the left hemisphere, subserving visual recollection, and he confirms this by the anatomical condition which he has now described—viz., the destruction of certain associational fibres of the occipital lobe. On reviewing all the circumstances of the case under consideration, he is of opinion that the following propositions may now be laid down: (1) That mind-blindness may arise through destruction of certain connecting fibres—for example, by lesions which lie close under the surface of the first and second occipital convolutions; (2) that symptoms of permanent mind-blindness, with complete homonymous hemianopsia or with hemiachromatopsia alone, are due to lesions in each occipital lobe affecting either the cortex or underlying fibres; (3) that the area for visual impressions and the area for visual recollections of one and the same hemisphere are in direct connexion; and (4) that if, when the visual area in each hemisphere is affected, the area for visual recollection in one hemisphere is unaffected, the disturbances of optical perceptions vanish when the eyes are closed. The case, it will be seen, is an extremely important one, and it will no doubt be the means of throwing light on many hitherto obscure problems.

#### VACCINATION AND SMALL-POX MORTALITY.

IT is a regrettable fact in the vaccination controversy that the opponents of this salutary measure should in their zeal to depreciate its value lose sight of essential principles. Thus in a letter which appeared in *The Times* of the 19th inst. Major-General Phelps of Birmingham cites the fact, which he says he has verified, that each of the four fatal cases of small-pox occurring amongst adults in that town last year were of vaccinated persons, but that this fact was not noted on the certificates of death. We agree with him that such an omission is to be deplored, but his own letter shows that the evidence of vaccination was obliterated by the severity of the variolous eruption in at least two of the cases. Still, if he has been able to procure unequivocal evidence—no easy matter, especially for a prejudiced inquirer—from the relatives of the deceased, it might have been equally possible to gain this information at the time of the illness. It should not be inferred that because the fact of vaccination is not mentioned on the certificate these fatalities would be placed amongst the "unvaccinated class." There is a sort of feeling amongst the opponents of vaccination that the interests of truth are not regarded by the upholders of the practice! They also seem to think that the mere fact of vaccination having been performed at all is considered by the profession to be absolutely protective against fatal small-

pox during the whole of life. If the former can show a mortality from this disease amongst the efficiently vaccinated at all approaching that amongst the nominally vaccinated and the unvaccinated, then, indeed, we may begin to question the efficacy of the practice. This demonstration *cannot* be made. Vaccination, efficiently performed and reinforced by revaccination, is—in the healthy—almost absolutely protective against the ravages of small-pox. That has been proved up to the hilt. But it has also been shown that the conditions for producing so certain an immunity are not invariably observed—nay, even that unscrupulous persons encourage the poor and ignorant to obey the law in the letter, but to obviate the effects of vaccination by artifice. Year by year in this country the numbers of the unprotected are increasing, and they include not only the really unvaccinated, but the nominally vaccinated also. Lastly, mortality from small-pox, as from all infective diseases, is influenced by the previous habits, health and age of the subject, and when all such favouring conditions for severity are struck off from each column of the vaccinated and unvaccinated alike, the disproportion of fatalities and, indeed, of severity of attack between the two classes is so evident that no one not absolutely blinded by prejudice can fail to perceive where the safety lies.

#### LATER STUDIES OF TIZZONI AND CENTANNI ON THE PROPHYLAXIS OF RABIES.

To combat the infection of rabies, even in its pronounced stage, the Bolognese pathologists, our readers will remember, employed the serum of the blood of rabbits which had received such immunity from rabies as to withstand without injury repeated inoculations of the virus. The active substance of the serum may be precipitated by alcohol together with other albuminoid bodies, and the precipitate so obtained, when redissolved in water, shows itself capable of neutralising the virulence of the medulla of a rabid dog. Professor Tizzoni, in concert with Dr. Schwarz, had already sought to ascertain if the alcoholic precipitate manifested on the organism the same beneficent virtues as the directly injected serum. His results, however, as then obtained were too uncertain and could not claim a definite character, all the more that the method of inoculation had in more than one particular to be brought to greater perfection. To solve the question he made use, in recent researches, of serum taken from animals which had resisted repeated inoculations, hypodermic and intravenous, of the virus, the serum being combined with ten volumes of alcohol and the precipitate obtained being dried and desiccated. To ascertain if the solid substance separated from the serum possessed immunifying (*immunizzanti*) virtues, direct inoculation of the rabid virus was practised on the sciatic nerves of rabbits, and eight days after this inoculation the animals were further inoculated with an aqueous solution of the precipitate. The immunifying action of the precipitate was expected to manifest itself after the virus had invaded the central nervous system and after the first symptoms of the malady had appeared. The results, checked by repeated experiments, showed in every case that the animals inoculated with the precipitate withstood the infection admirably, while the animals which had been inoculated with the rabid virus, but had not been subsequently "vaccinated," died within twenty days of rabies. Which proves that, in analogy with the findings of Professor Tizzoni and Dr. Centanni with the anti-toxine of tetanus, by means of absolute alcohol we can get a precipitate which possesses the same immunifying power as the serum, for which, in fact, it can be substituted. The importance of the preceding fact, scientifically and practically, can scarcely be exaggerated. It confirms the immunifying virtues of the serum, it introduces us to a new property of the active substance contained in the serum;

and finally it admits of our getting this substance in a form which renders it capable of being kept easily and for an indefinite time. It is thus possible to collect by little and little from the serum of immunified animals considerable quantities of the active substance, so as to have it at hand in case of need; it is also possible to pack and forward it to places at a distance. Its mode of use, moreover, is of the simplest. Professor Tizzoni and Dr. Centanni concluded their interesting communication (made to the R. Accademia dei Lincei of Rome) by the avowal that they could not pronounce exactly on the minimum dose of precipitate necessary to cure a rabbit affected with rabies; in their experiments they say that from the desire to obtain positive results they perhaps exaggerated the doses required to produce immunity. In any case, even if this minimum dose were established, it would not have been possible, by simple proportion, to draw deductions applicable to the human patient. With respect to the organism of the rabbit, that of man is so differently conditioned for the infection of rabies that only from actual proof gained from the experience of the human patient can we hope to ascertain the effective minimum dose of the immunifying substance.

#### ACTION OF ALKALOIDAL POISONS ON LEUCOCYTES.

DR. E. MAUREL of Toulouse has performed an important series of experimental researches on the action of poisons on leucocytes. The results are published in recent numbers of the *Bulletin de Thérapeutique*, and an abstract will be found in the *Boston Medical and Surgical Journal* of August 11th of this year. With regard to strychnine, he finds that the toxic action of the alkaloid on the animal economy is in the ratio of its destructive action on the leucocytes. "In poisoning by sulphate of strychnine, the death of the leucocytes and that of the animal are simultaneous." The quantity of strychnine necessary to kill immediately all the leucocytes in 100 grammes of human blood has been found to be 5 centigrammes; this amount of blood may be said to represent 1 kilogramme of the weight of the body. A much smaller quantity of strychnine—2 centigrammes—is equally fatal to the leucocytes in 100 grammes of blood, though several hours are required for their complete destruction. The immediate effect of the poison on the white corpuscles is to arrest their spontaneous activity and fix the elements in the spherical state. In investigating the action of atropine on the white corpuscles Dr. Maurel found here, too, a complete concordance between the quantity of toxic material necessary to kill the animal and that necessary to kill the corpuscles. Struck by this concordance, which suggests a special rôle of the leucocytes in death by this toxic agent, Dr. Maurel experimented with the hare—an animal which eats belladonna with impunity—to ascertain if the leucocytes of the hare's blood are affected by atropine. He found that this alkaloid was almost without effect on the leucocytes of the hare. His conclusions are formulated as follows: In the dose of 5 centigrammes or more sulphate of atropine instantly kills the leucocytes contained in 100 grammes of human blood. In the dose of 2 centigrammes these elements can live but a few hours, and from the moment of contact they present sensible modifications in their activity and in their form. In the hare, on the contrary, the leucocytes can live in a solution of 2 grammes of atropine to 100 grammes of blood, and perhaps in a stronger solution. Lastly, considering the concordance between the quantity of sulphate of atropine necessary to kill a man and that which suffices to kill the leucocytes of human blood, or impress upon them important modifications, considering, moreover, that the immunity of the hare is closely associated with the immunity of its leucocytes, Dr. Maurel is led to the conclusion that it is probable that

the leucocytes have a principal part to perform in poisoning by that alkaloid. Similar investigations relative to pilocarpine have shown that it takes 10 centigrammes of that substance to instantly kill all the leucocytes in 100 grammes of human blood; 5 centigrammes will kill them in a few hours. In another series of experiments Dr. Maurel investigated the action of cocaine on the white globules, and he concludes that death by cocaine is the consequence of the death of the leucocytes or of modifications which the latter sustain under the influence of this agent. The quantity of cocaine which is immediately fatal to the leucocytes is 1 per cent. of the quantity of the blood or about 1 gramme per kilogramme of the weight. Thirty times as much cocaine is required to kill an animal when this salt is taken by the mouth as when it is injected into a vein. In death by intravenous injections of toxic solutions the death may be caused by the leucocytes suddenly killed being swept along the blood stream and acting as emboli. These elements, in fact, after their death, take the form of rigid discs, the long diameter of which exceeds by one-third at least the calibre of certain capillaries.

#### "THE POOR AND SHAM DOCTORS."

THE *Morning Advertiser* reports an inquest under the above heading on the body of a child, in whose case a "doctor" was fetched by the father, who placed a tube on the chest, and said it "was not dead." He then said he was not "the doctor," "the doctor was away." On hearing that he purported to come from "Dr. Morrison's" in Cannon-street-road, the coroner, Mr. Wynne E. Baxter, said, "I should think he is away; he has been dead and buried a long time." This disclosure led to some uncomplimentary remarks on the kind of assistants kept by some medical men. The foreman of the jury said the question was one of great importance to the working classes and should be reported to the Medical Council. Dr. George Hill Bartlett, who was called to see the child after the visit of the gentleman who said "he was not a doctor," expressed the belief that the child was dead in the first instance. The coroner agreed to report the case to the Medical Council. The question, as the foreman says, does deeply affect the working classes, but they have the remedy in their own hands. Every respectable working man should have an understanding as to medical attendance with a neighbouring practitioner. In every neighbourhood there are medical men who are willing to meet the case of the working classes on reasonable terms. The Medical Council has its own duties, however, in regard to the question of covering.

#### CEREBELLAR CYSTS.

IN the *International Journal of the Medical Sciences* for August of this year is an important paper by Dr. R. T. Williamson on this subject, with special reference to the occurrence of simple serous cysts in the cerebellum. He gives the details of two cases presenting the ordinary clinical features of cerebellar tumour, in each of which the necropsy revealed the existence of cysts in the cerebellum, which appeared at first to be simple, and only on very careful examination of numerous parts of the cyst wall were they found to be really the result of new growth—in the one case gliomatous and in the other sarcomatous. Dr. Williamson, while not denying the possibility of so-called simple or serous cysts originating in other ways, is inclined to think it more probable that these cysts have been tumours in which the cystic degeneration has been so marked and so extreme that the whole of the tumour growth has disappeared, or only so minute a portion has remained that it has escaped detection. His reasons for this view are briefly as follows:—That the clinical history in such cases is the usual one of tumour, and that the liability of intracranial tumours to undergo cystic degeneration, as is well known, is very great. In some cases also what have been regarded as

simple cysts have been shown on very searching examination to contain in the wall a small mass of new growth, and this mass in one case was so small as to measure no more than  $\frac{3}{8}$  in. by  $\frac{1}{8}$  in., a considerable portion of which consisted of bloodvessels. Further, Dr. Williamson urges that, if the cystic degeneration can be so marked that only a patch of new growth of these minute dimensions may remain, it seems not improbable that in some cases the whole of the tumour may disappear and only a cyst remain; or the portion left may be so small as to escape detection. The occurrence of such cysts in the cerebellum suggests the possibility of treating some of the supposed cases of cerebellar tumour by aspiration and drainage. Operations for the removal of cerebellar tumour are notoriously unsuccessful on account of the difficulty of the localisation and of the operation; and if there is any reasonable hope that a cyst is present, naturally the treatment suggested would be adopted. Nor is there any reason why such treatment should not be extended to the cerebrum, as was actually done in a case which Dr. Williamson quotes as recorded by Oppenheim and Köhler. This was a case of Jacksonian epilepsy in which at the operation a cystic glioma was found in the right motor area. The superficial part only of the growth was removed and the cavity drained, with the result that the left arm, which had been paralysed, regained power, and the patient otherwise improved so much that he was discharged in good health three months after the operation.

#### THE ISOLATION OF DIPHTHERIA IN BOOTLE.

WE regret to see that a proposal by the chairman of the health committee of the Corporation of Bootle has been rejected in the Town Council by a majority of one. We regret this the more as the opposition to so reasonable a proposal was led by a medical man, Mr. Wills, who moved an amendment that, in the opinion of the Council, the pavilion was unnecessary. In the course of his speech he characterised the report of the resident medical officer as "sensational," complained that the time of the Council should be taken up with such unnecessary propositions, and wound up by saying that diphtheria was not infectious. The chairman then disclosed that a diphtheria patient admitted into the fever hospital had taken fever and died. But Mr. Wills obtained the victory by one vote. The triumph is an unsatisfactory one and ill-founded. It is a grievous thing to take a patient with one infectious disease into a hospital meant for another, and to convey the second infection to him. To say that diphtheria is not infectious but contagious is to draw an unpractical and academic distinction. Besides, the question is not open for discussion. It has been settled by Act of Parliament, which has defined certain *infectious* diseases, of which diphtheria is one, and a very deadly one, which should be isolated as much as any disease of which we know. We venture to hope that Mr. Wills will reconsider his action on this very serious matter.

#### FLOWER CULTURE AMONG THE POOR.

WE lately touched upon the movement, now extending in our great cities, which has for its object to sweeten and brighten the bitter and sombre lives of our toiling masses, and we indicated more than one direction in which it had already resulted in good. The flower culture it seeks to encourage must, indeed, bring with it many more blessings than the moral and intellectual elevation and refinement it inspires, and among these the practical knowledge it tends to give of plants, their characters, their virtues, their uses, and also of their dangerous properties, is by no means the least. How often does ignorance of the nature and qualities of fruits and seeds, roots and leaves, incur illness and even death when these are incautiously tasted or

eaten in field or wood or byway? How often are not symptoms of the most alarming, even fatal, kind induced by the consumption of non-edible mushrooms, or by mistaking *Aconitum Napellus* (monkshood) for horse-radish? The other day five children narrowly escaped poisoning by eating the seed-pods of laburnum, and, almost in the same breath, we hear of fifty-eight boys in an industrial school in the south of England chewing laburnum roots for stick-liquorice, and shortly thereafter being treated in hospital for the symptoms of narcotic poisoning. A garland of laburnum flowers worn round the neck has been said to produce headache, and a correspondent tells us of a boy mistaking and eating laburnum seeds for green peas, with the result that but for prompt medical intervention he would have died. The knowledge by which such risks are avoided is one among the many advantages that must flow from the plant and flower culture now philanthropically promoted among the humble denizens of town and village and ought to be still further developed by the action of our Board schools in following up the initiative started in city court and street alley. We must not expect too much from our educational system in its present state, nor may we hope to find botany included in the programme of our elementary schools. But surely some practical familiarity with the names and characters and properties of our wild flowering or fruit-bearing plants might be given at that stage of education, in supplement of the knowledge now eagerly sought after—as we have seen—among masses of the population to which the joy of window-gardening was, till lately, but a dream.

#### GLASGOW UNIVERSITY CHAIR OF SURGERY.

THERE is a maxim in the Koran that "a ruler who appoints any man to an office when there is in his dominions another man better qualified for it sins against God and against the State." The principle of this maxim has unfortunately not always been followed in the appointments made to the chairs in the Scotch Universities. We need not refer to several in which political or religious opinions were apparently recognised as requisites for these appointments rather than the candidates' knowledge of the subjects they were called upon to teach, or their contributions to the advance of their special departments. Fortunately the vacancy caused by the lamented death of Sir George H. B. Macleod has been filled by the appointment of a Glasgow surgeon whose claims for the post cannot be excelled. A distinguished student and graduate of the University and a former assistant of Professor Macleod, Dr. William Macewen has for long been regarded by the profession in Glasgow in the west of Scotland as the future Professor of Surgery at Gilmore Hill. Dr. Macewen was formerly lecturer on Clinical Surgery at the Royal Infirmary, Glasgow. He has been laboriously working there with his students, not only as a clinical teacher, but in enunciating the principles of surgery, and for many years sacrificing mere money-making to the advancement of surgical knowledge by his numerous clinical and pathological observations in the wards and post-mortem theatre as well as in the laboratory. As a result of his continued labours his name will for ever be associated in British surgery with osteotomy, transplantation of bone, brain and spinal surgery &c. Referring to his paper read before the Royal Society in 1881 in regard to the unique case of bone transplantation, we wrote: "Great interest attaches to this case, which is the first of the kind recorded, and Dr. Macewen is entitled to warm praise for devising and carrying to such a successful issue the many details necessarily involved in its management." Dr. Macewen's name is perhaps best known throughout the world in connexion with osteotomy. His book is the standard work on the subject, and has been translated into most European languages. He is about to publish in con-

nexion with his researches on Brain Surgery an excellent and most complete atlas of Sectional Anatomy of the Head, which will throw considerable light on our present ideas of the relation of parts within the cranium and prove of great service in enabling surgeons to localise lesions which antiseptic surgery can relieve. We understand that Dr. Macewen was the first to be offered the Professorship of Surgery in the Johns Hopkins University, Baltimore, but he did not accept that distinguished honour. In 1888 at the meeting of the British Medical Association in Glasgow the ovation he received when he delivered the special lecture on his work in connexion with Brain and Spinal Surgery will not be readily forgotten. In acknowledgment of this work his *alma mater* conferred on him the honorary degree of LL.D., and now she is to be congratulated on his appointment to the Chair of Surgery.

#### "ARE MIRACLES UNNATURAL?"

It would be no simple matter, if indeed it were not absolutely impossible, for us to succeed where so many have failed, and to settle the vexed question as to how far miracles are or are not the effects of natural agency. In approaching the subject we are met first by the difficulty of evidence—viz., how far we may trust to the accounts given of reputed miracles. Doubtless these are in almost every known case capable of misrepresentation and especially of exaggeration. The mental attitude of expectant onlookers lends itself to this, and we should not therefore be disposed to admit in such cases any testimony but that of entirely dispassionate and accredited witnesses. Again, there is the question whether, if a miracle has occurred (the term is suggestive merely of a remarkable occurrence and not necessarily of something supernatural—that is to say, unnatural), it is not still permissible to ask if the method carried out in this wonderful occurrence did not consist in a stimulation, abnormal it might be, of natural activities. Wonders which fall within this category happen daily and hourly. They are true miracles. They are also natural. They exhibit, we might say, the mode of operation commonly preferred by the Divine Being. Therefore we would again suggest that there underlies the whole series of miracles a similar mechanism, perhaps undiscovered but always natural, and therefore more, not less, characteristically divine.

#### THE FUNCTIONS OF THE STOMACH AFTER GASTROSTOMY.

SOME important investigations as regards the functions of a stomach which has been subjected to gastrostomy have been made by Professor Ewald. His results are published in the *Deutsche Medicinische Zeitung* of March 24th.<sup>1</sup> In the case described by Professor Ewald the peptic activity of the stomach was entirely destroyed and the principal processes of digestion took place in the intestines. The movements of the stomach were lessened and a certain amount of stagnation of the gastric contents occurred in consequence of adhesions. Professor Ewald has therefore suggested that the fistula should be made near the pylorus, so that the food, or at least some of it, can be introduced by a tube directly into the duodenum. So long as the patient's strength is maintained gastrostomy cannot be strongly recommended. The prognosis of obstruction due to pressure from without is much the same as that due to tumour, unless the stricture be due to syphilis. The stricture may be caused by ulceration in the lower part of the œsophagus; this lesion is probably due to corrosion by the gastric juice, and occurs principally in anæmic subjects. The age is very important. Unlike cases of carcinoma, attacks of pain are noted first and obstruction later. The patient upon whom Professor Ewald made his

observations was a woman aged twenty, who had previously suffered from gastric symptoms, and then had enjoyed an interval of health lasting some months. About one year before the patient came under observation the pain began again, followed by difficulty in swallowing. A bougie could not be passed. There was wasting; no history of syphilis could be obtained. Gastrostomy was performed by Professor Oppenheim, and the opening into the stomach was made at the end of five days. The patient gained rapidly in weight, but the constriction did not relax sufficiently to permit of the passage of a bougie. The fact of dilatation of the stomach, with delayed passage of food favoured the diagnosis of a cicatrised ulcer near the pylorus as well as in the œsophagus. Through a speculum the cardiac end of the stomach appeared too red and the pyloric end too pale. The sound could be passed five inches upward and six inches downward, but it could not be made to pass into the gullet or duodenum. The pressure in the moderately filled organ was estimated by Professor Ewald at from 30 to 35 millimetres, and with moderate internal compression at from 80 to 100 millimetres. The pressure was increased by applying the faradaic current to the abdominal wall, but not by applying the current to the inside of the stomach. This was due to the presence of adhesions. Salol excretion was delayed, salicylic acid appearing in the urine two hours and a half after food, this being due to the dilatation of the stomach. If the stomach were washed out the night before, a fluid containing free hydrochloric acid and possessing peptic properties could be obtained on the following morning. The patient survived the operation five months.

#### MEDICINE AND THE STATE.

THERE can be little doubt that a sense of personal indebtedness has had something to do with forming in the mind of Mr. Gladstone that favourable opinion of the medical profession which he is known to entertain. We must, however, look for some other source of inspiration if we would rightly appreciate his latest reference to this subject. When we find him saying that the profession is in a state of absolute advance owing to the progress of its science, we recognise no more than the acknowledgment of an evident fact. When again he speaks of advance referable to particular features which connect that onward movement with the progress of modern civilisation, we note that he has been duly observant of the silent evolution which is daily recasting into newer forms the relations of the nation with its medical advisers. It has been reserved for a comparatively late period to witness the gradual absorption of much that is medical into the science of Statecraft. No longer do we think of this latter faculty as concerned merely with the maintenance of peace, commerce and justice between different communities. These purposes continue, but we have added to them much more that has to do with individual and public health and happiness. Politicians of less sensitive intelligence than the aged Premier, who is himself a monument of personal hygiene, would do wisely to reflect upon the character, duties, and legitimate public utility of the power which medicine exercises in the government of states.

#### THE MECHANISM OF BRAIN INJURIES.

In the last number of *Brain* Mr. Alexander Miles discusses this subject with reference chiefly to the causation of the condition which follows concussion. The subject has been investigated experimentally and elucidated by a consideration of the function of the cerebro-spinal fluid and of the various theories of concussion which have been brought forward. The effect of concussion on the heart and the general circulation, as well as on the circulation in the brain, has been considered and the important rôle which the corpora testiformia are believed to play in the production of vascular disturbance is

<sup>1</sup> Abstract in the Journal of the American Medical Association, July 30th, 1892.

discovered. Details of the various experiments are given and the resulting post-mortem appearances described. They are such as to lead Mr. Miles to lend his support to the theory of the important part played by the cerebro-spinal fluid in the mechanism of cerebral concussion. His conclusions, as given in the summary at the end of his paper, are that the group of phenomena commonly spoken of as "concussion of the brain" result from temporary anæmia of the organ consequent upon stimulation of the restiform bodies and perhaps other structures in the region of the bulb. The stimulation of these parts is supposed to be effected by the wave of cerebro-spinal fluid which rushes through the aqueduct of Sylvius and the foramen of Magendie and from the subarachnoid space of the brain to that of the cord when a severe blow is dealt over the skull. Such a wave will naturally disturb the equilibrium of the nerve cells throughout the central nervous system, and the hæmorrhages found throughout the brain substance and on its surface are to be ascribed to the recession of the cerebro-spinal fluid which supports the bloodvessels of the brain. He is further of opinion that the petechial hæmorrhages found in cases of so-called concussion are not to be regarded as the proximate cause of the symptoms of that condition, but rather as an index of the force producing the injury.

#### DRUNKENNESS AMONG WOMEN.

THE *Daily Telegraph* devotes a column to the discussion of what is called "A National Shame: Drunken Women." No one who has his eyes open can fail to see that women are fatally losing modesty in the way in which they enter public-houses. Our contemporary quotes evidence from coroners, magistrates, police-court missionaries and others, all with one consent agreeing that drunkenness among women is on the increase. Young women are not excepted, but included in the statement. Mr. Wynne Baxter has said that the question of drunkenness, directly or indirectly, enters into half the inquests he holds. In 1891, in London, 8373 women were taken into custody for being "drunk and disorderly." Of 2554 women appearing at Clerkenwell, 95 per cent. were the victims of drink. Magistrates and missionaries are convinced that prison does nothing to benefit drunken women, and that they should have the power of dealing with them quite differently from ordinary criminals. This is quite obvious, but we must aim at measures which check the creation of drunkards in homes and streets.

#### THE BIRKBECK PANIC: A MANIACAL EXCITEMENT.

THE saying that "apprehension kills and apprehension cures" is of the nature of a truism, for apprehension caused the Birkbeck depositors to withdraw their money and apprehension (of otherwise losing it) caused them to replace it. Panic arises from a more or less unreasonable disturbance of that sense of security which ought to rest in all social institutions, whether commercial or structural. The sanctions of civilised life have their highest expression in this sense of security, which is totally wanting in the methods of savage existence. But while, on the one hand, a sense of security is regarded as characterising the body politic, individuals have, on the other, to be careful to cultivate the faculty of self-control which forms, as Herbert Spencer has said, a chief distinction between the human being and the brute. The "possession" of the swine by a legion of devils and their subsequent self-destruction serve well to illustrate the outcome of muscular activity where this governing faculty is conspicuous by its absence. Panic in human beings is the counterpart of this condition of things; and it is neither more nor less than a maniacal excitement with, among other symptoms of derangement, loss of appetite, watchful and sleepless nights and a total

incapacity to think soberly on any subject, the whole mind being absorbed by the one idea which swamps all its ordinary activities and diverts them from a normal, healthful flow into an insane rush of selfish impetuosity. The evils of such a rush as that upon the Birkbeck Bank are not finished when the panic has been lulled, as in this instance, by the evidence of stability and safety. The injurious effects upon individuals are not easily surmounted, and the medical profession is only too well aware of the serious extent to which the resulting nervous exhaustion and prostration are now beginning to make themselves felt among those directly or indirectly concerned in the foolish and needless excitement. The full and ultimate chronicle of such panics is written in the case-books of our lunatic asylums; and although we are well aware of the futility of advice in dealing with actual panic, we nevertheless feel it to be our duty to issue a note of warning on the subject, and to impress upon all the great necessity of cultivating and exercising in every walk of life and under every circumstance in life the all-important moral attributes of self-control, self-restraint, self-government.

#### THE MUSCULAR SENSE.

AT the eighteenth annual meeting of the American Neurological Association, held in New York in June of this year, an interesting paper was read by Dr. G. F. Preston of Baltimore on some Contributions to the Muscular Sense.<sup>1</sup> Dr. Preston thought that it might be considered definitely proved that the muscular sense, or at least one part, was composed of afferent impulses which were entirely independent of general sensibility. The next step that suggested itself was the starting-point of these afferent impulses. Clearly, as several observers had noted, the muscles alone—that was, sensations coming from them—could not give us the information we required as to the position of our limbs. Undoubtedly the tendons, the joints and their coverings, and perhaps the bones, all aided in producing the posture sense, or rather from these proceeded nerve fibres conveying posture-sense impressions. The loss or impairment of posture sense was an almost constant symptom in sclerosis of the posterior columns of the cord. It seemed probable to Dr. Preston that the fibres conveying posture-sense impressions passed into the restiform body, thence to the cerebellum and on to the great brain. In three cases of tumour of the cerebellum in which necropsies had been made he had observed loss of posture sense without impairment of general sensibility.

#### FEVER IN LONDON.

THE embarrassment of the Metropolitan Asylums Board with the extension of the epidemic of scarlet fever is very great, and, judging from previous epidemics, more pressure is yet to be expected. As early as May 14th the Ambulance Committee reported the number of cases to be larger than on the same day in any previous year. Out of 3744 patients under treatment, no less than 3353 were cases of scarlet fever. The ages of the patients are instructive. Out of 7794 fever patients admitted to the Board's hospitals between Jan. 1st and Sept. 12th, 74 per cent. were between one and ten years of age, 16 per cent. between ten and fifteen, and only 10 per cent. over fifteen. The Asylums Board have reached the limit of their accommodation and have been obliged to decline a large number of cases. The chairman of the Board, Sir Edwin Galtsworthy, at the meeting on the 17th inst., severely and with much iteration reflected on the Local Government Board for its "lamentable" delay and indecision in agreeing to the proposals of the managers for plans for meeting the unprecedented number of cases. The public will await with anxiety the defence of the Local Government Board. Meantime it appears to us as if this wholesale reception of

<sup>1</sup> Boston Medical and Surgical Journal, Aug. 26th, 1892.

cases from all classes of the community was a mistake. It is interminable and it is of questionable utility. Anybody, in however good a house, who does not like the care, cost and trouble of isolating a case of scarlet fever may send it to the hospitals which were meant originally for the poor. The law has been altered so as to allow of this without the discredit of pauperism and for the bare cost of maintenance. Is this alteration of the law justified by the results? It seems a time for questioning whether the system is diminishing the number of cases, as it certainly seems diminishing the independence of the people. Of course we entirely approve the isolation of cases occurring in the houses of the poor.

#### THE CAPE MEDICAL ACT.

THE medical profession is petitioning the Cape Legislature for an amendment of the Act lately passed, and very reasonably so. One claim in particular, leaving the practice of midwifery to uncertificated women without pain or penalty, but subjecting certificated midwives and medical men to penalties for breaking regulations to be made by the Medical Council, gave great and just offence to the profession who claim, as educated and qualified practitioners, to be a law to themselves. It is said to have the effect of hindering medical men from taking obstetric practice, and may easily tell badly against lying-in women by leaving them to be attended by the unqualified and the ignorant. We would point out to Mr. Sauer and other promoters of this Bill that such penalties are for those who are under no obligation of honour and position. Medical men have their own reputation and that of their profession to maintain, and may be trusted to take those precautions which science and self-interest alike dictate.

#### CHOLERA NURSING.

WE would direct attention to an excellent little lecture to trained nurses by Dr. Heron, physician to the City of London Hospital for Diseases of the Chest, on some important points in cholera nursing, which has been published by the Royal British Nurses' Association. The lecture was given on the 1st and 5th of the present month to over 400 trained nurses. After referring very briefly to the history of the disease and giving a graphic description of its symptoms, the lecturer states in clear and precise terms what is known about it with direct relation to the practical bearing which Koch's discovery of the comma bacillus, as its cause, has upon our methods of dealing with persons suffering from cholera. From this point of view the lecturer lays down with much perspicuity the precautions that have to be taken, the disinfectants to be used and the method of using them, the dresses that should be worn, and the course which should generally be followed in regard to the patient and the nurse.

#### "ELECTROPATHIC" ADVERTISING.

IT is with painful surprise that we find the name of a member of our profession appended to a highly eulogistic letter addressed to the head of a firm that is now deluging the British public with advertisements of its wares, which are alleged to be panaceas for almost every ill. The medical practitioner in question is an M.D. of St. Andrews, a Fellow of the Edinburgh College of Physicians, a Licentiate of the London College, a Member of the College of Surgeons of England and a Licentiate of the Society of Apothecaries. Our contemporary, the *Electrical Review*, in its issue of this week, not only exposes the fallacies underlying the "experiments" upon which this precious recommendation was penned, but also speaks in no measured terms of the wrong done to the profession and the public by this advocacy of an "electropathic" appliance.

We may leave the electrical experts to judge of the scientific value of the grounds for that advocacy; but we cannot, for the honour of our profession, refrain from expressing our strong disapproval of the uses to which the physician in question has applied his knowledge. He cannot fail to be conscious of the infinite harm that may accrue from one in his position giving such warm commendation to a method of treatment that is so closely bound up with quackery. Nor could he doubt that an opinion so directly addressed to the firm would be made the most of, and that his *littera scripta* would be sent broadcast through the land in support of a speculative enterprise which feeds on the ignorance and folly of the multitude.

#### THE PUBLIC HEALTH OF ITALY.

AN Italian correspondent writes under date the 18th inst.: "La Direzione Generale di Sanità, having been informed of the reports in American and French journals as to the occurrence of cholera cases at Naples, gives a categorical denial to such reports. The public health at Naples and in the Islands of Capri, as well as throughout the Italian kingdom, is exceptionally good; above all, there has not been verified a single case of any malady which can awake the slightest suspicion of the presence of cholera. This satisfactory result is mainly due to the steady, thorough and effective surveillance practised at the frontier, without causing any inconvenience to the traveller. Only articles of personal use and actually soiled were subjected, and that immediately, to the disinfecting process."

#### SCARLET FEVER AND MILK.

A SOMEBWHAT sharp outbreak of scarlet fever is reported at Leyton in Essex. It has transpired that most of the sufferers were supplied with milk from a single dealer who obtains his milk from Ongar. It is further reported that at a farm at Ongar, from which this dealer obtains his milk, scarlet fever is prevalent in the family of the farmer. Urgent and careful inquiry into this outbreak will doubtless be made without delay.

#### SOME HORRORS OF QUACKERY.

THE old proverb "any port in a storm" has often found practical illustration in the empirical treatment of disease. Time was when even regular practitioners in the art of healing included in their professional armament, along with many simple remedies of real value, other matters the very mention of which might almost suffice to engender illness. We may feel thankful that we have now entered upon a later and more scientific era, and that such extraordinary drugs as weasels' gizzards, does' hoofs, snails and other even more repulsive horrors do not now find a place in any pharmacopœia. There still exists, however, a species of medical folk-lore, and some of its prescribed wisdom available for use in illness is of the most remarkable kind. Times of panic, by throwing a population to some extent on its own resources for treatment, are apt to create a demand for these survivals of a dark age. This happened lately in Germany where a toad cooked with much care was swallowed as a cure for cholera. As to the result we are not informed. Most of us would probably choose to suffer rather than thus attempt our own relief. One can easily understand how such remedies as these have gained their favourable reception among ignorant persons. Used first, in all likelihood, in some case of illness mistaken for an incurable disease, the nostrum has been followed by spontaneous healing, and has carried the stolen credit and the faith which goes with reputation to other sick bedsides, sometimes with like spurious results. It cannot be doubted that some such confidence in the horrors of empiricism lingers amongst our own poorer population, especially in country districts. In view of this fact the practice lately adopted by

local vestries of inculcating active sanitary measures as the true preventive of infection and impressing the necessity of obtaining prompt medical aid cannot be too highly commended.

#### SMALL-POX IN THE PROVINCES.

THERE have been some fifteen cases of small-pox reported at Pateley Bridge in Yorkshire and three persons are to be prosecuted for failing to notify the disease. The rural authority are endeavouring to secure an old workhouse building as an isolation hospital. Small-pox is also reported to be spreading in Manchester, where, however, extra facilities for vaccination and revaccination are being offered to the public by the authorities concerned.

#### CHOLERA AND CLEANLINESS IN RUSSIA.

THE article on this subject in the current issue of the *Fortnightly Review* affords a good deal of information about what may be termed the internal economy, social life and condition of the Russian population. The picture presented to us is a most unsatisfactory one in every way, and we hope that matters are not, after all, quite so bad as they are painted. The writer says the plain truth is that, from a hygienic point of view, there is not a sound spot in the empire; food, water, air, clothing, houses, streets are all contaminated to such a degree that a Russian newspaper lately remarked that a century of effort would not suffice to bring about a perceptible improvement.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Dorpat.*—The chair of Internal Medicine, vacated by Professor Unverricht, has been filled by the appointment of Dr. S. M. Vasilieff, editor of the Russian journal *Meditzina*.

*St. Petersburg (Medico-Chirurgical Academy).*—There are at least a dozen candidates for the chair of Special Pathology and Therapeutics, vacant by the resignation of Dr. Manassein, editor of the *Vrach*, amongst whom may be mentioned Professors Kurloff of Tomsk and Afanasieff of St. Petersburg.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Anders Anderson, formerly Professor of Midwifery and Gynæcology in the Carolin Institute, Stockholm. He was also at one time President of the Swedish Medical Society. He was seventy years of age.—Dr. Deck of Laisheff, in the Province of Kazan, a well-known cholera district medical officer, at the age of fifty-three.

IN connexion with the opening, a few days ago, of the temporary small-pox hospital at Warrington, a circumstance occurred calculated to direct attention to the necessity, during the prevalence of an epidemic, of increased care in ascertaining the reality of the death of any patient. An infant, three weeks ago, was supposed to be dead from small-pox, and hasty instructions were given to an undertaker to supply a coffin. In the meantime the child was placed in a shell to be taken to the mortuary preparatory to burial. Before, however, the preliminary steps attending inhumation were completed the infant began to show signs of animation, and it was not until some hours afterwards that the actual demise took place.

MR. G. Q. ROBERTS, M.A. Oxon., has been appointed House-Governor of the London Hospital, in the place of Mr. W. J. Nixon, who has resigned after forty-six years' occupancy of that post. The combined offices of house governor and secretary will now be held by Mr. Roberts.

THE patient on whom Dr. James Murphy performed gastrotrachy at the Sunderland Infirmary on the 9th inst. died on the 19th inst., thus having survived the operation ten days. After having rallied from the shock of the operation she continued remarkably well till the 17th, when she became very much exhausted and gradually sank. On post-mortem examination the abdomen was found to be quite dry and the wound in the stomach absolutely air-tight, having contracted an adhesion with the liver, but it was not cicatrised, and immediately opposite on the posterior wall of the stomach was another ulcer the size of a sixpence, in which the mucous membrane had been eroded, but the peritoneal covering had been strengthened by an adhesion to the pancreas.

DR. ADAMI, Fellow of Jesus College, Cambridge, and formerly of Owens College and of the Manchester Royal Infirmary, has been appointed Professor of Pathology in the University of Montreal, Canada.

THE Queen has been pleased to appoint Alexander Ogston, Esq., M.D., Regius Professor of Surgery, University of Aberdeen, to be Surgeon in Ordinary to the Queen in Scotland, in the room of Sir George H. B. Macleod, deceased.

AN anonymous donor has presented a Bank of England cheque for £1000 to the Essex and Colchester Hospital. A gift of £500 has also been made anonymously to the fund for providing a public park for Colchester, and a similar sum has been given by Mr. S. F. Harnard towards the erection of a public library.

THE Queen has approved the appointment by Sir George Trevelyan of Dr. William Macewen to be Regius Professor of Surgery in the University of Glasgow, in the room of the late Sir George Macleod.

PROFESSOR VIRCHOW'S friends on Wednesday last celebrated the twenty-fifth anniversary of his first election to the Prussian Parliament, in which he still represents the Third Berlin constituency.

MR. FIELD will deliver the Harveian Lectures this year, "On the Pathology and Treatment of Suppurative Diseases of the Ear."

It is announced that the examination in Sanitary Science at the University of Cambridge will be held from Tuesday, Oct. 4th, to Saturday, Oct. 8th next.

MATER MISERICORDIÆ HOSPITAL.—It is contemplated by the managing committee of this hospital to erect a building which shall be isolated and situated at a distance from the main building, for the reception of patients suffering from infectious diseases. It is further proposed to establish a convalescent home in connexion with the hospital. This will necessarily cause a considerable expenditure, and the authorities have appealed for funds to carry out the necessary improvements. There are now 311 beds available for patients and the daily average for the last ten months of 1891 was 291.6.

METROPOLITAN ASYLUMS BOARD.—The number of patients remaining in the several fever hospitals of the Metropolitan Asylums Board on the 20th inst. was as follows:—Eastern Hospital—416 scarlet fever, 63 diphtheria and 40 enteric fever; North-Western Hospital—414 scarlet fever, 88 diphtheria and 22 enteric fever; Western Hospital—302 scarlet fever, 47 diphtheria, 3 typhus fever and 11 enteric fever; South-Western Hospital—305 scarlet fever, 56 diphtheria and 24 enteric fever; South-Eastern Hospital—399 scarlet fever, 22 diphtheria and 11 enteric fever; Northern Hospital—801 scarlet fever and 20 diphtheria; Gore Farm Hospital—741 scarlet fever. On the hospital ship *Atlas* there were 3 cases of small-pox.

## CHOLERA.

### SOME CHOLERA COMMENTS.

THE epidemic of cholera is, we are glad to say, decreasing. The tide of cholera literature has consequently now begun to ebb. One thing seems absolutely certain, which was, however, well known before, and that is that the disease may be contracted in one place and carried to another or to several other places before it manifests itself. During the progress of the present epidemic we have had ample evidence of that fact as regards vessels from Hamburg, Havre and other ports. The epidemic has not manifested itself in any great force except in Russia and at Hamburg, notwithstanding that it has prevailed for so many months in the neighbourhood of Paris and the River Seine. The civilised world believes, and prudently acts on the belief, that there is such a thing as cholera infection and that a cholera patient is the source of it, specially so, by and through the micro-organisms contained in the discharges from his stomach and intestines; and we have taken a firmer grip, as it were, of the lessons taught by bacteriological science and its discoveries. It is possible, if it be proved that the comma bacillus is veritably and indeed the cause of cholera, that further researches into its life-history may show that the so-called cholera bacilli can assume a resting or spore stage and undergo certain changes of form under conditions which as yet remain to be demonstrated. Meanwhile, we can only adhere to the more exact scientific methods in the prosecution of our observations and researches.

There are still several points in the history of cholera epidemics which need further elucidation. While it is generally accepted that the disease spreads along the lines of human intercourse and has to be introduced into any given place, and can then only take root, establish and develop itself where it finds suitable nurseries and conditions, there are many persons who contend that it goes nevertheless by roads and methods of its own, pursues a definite course, advances in that area or province which for the time forms its natural limit, that it does not transgress such limits out of due season, even where the conditions as regards the movements of human beings seem favourable for its conveyance, and that it does not radiate equally in all directions from every given centre or outbreak, nor does it commonly take a retrograde course. The reply to this line of reasoning must be carefully sought for in a history of all the facts of the present epidemic. The very rapid extension of the disease on this occasion, for example, if attributable to the increased facilities for its transport, is an important consideration which requires to be thoroughly threshed out. On the other hand, it is quite conceivable that the introduction of its specific cause into any given place may not be at once followed by its active manifestation in epidemic force. This may follow later on, after a period of apparent latency or dormancy. Can any light be thrown on the causes or conditions under which an epidemic or outbreak stops? When the micro-organism on which the morbid phenomena in the affected individual depend is multiplied and reproduced at such an enormous rate it is difficult to explain the cessation of an outbreak without calling to our aid some such hypothesis as that it ceases from exhaustion of the suitable material, or that it dies out like a fire from want of fuel, in that the susceptible population have either fled from the sphere of its influence or been already attacked by it. It must be borne in mind that we are only acquainted with the presence of cholera by its manifestations in human beings—they supply, as it were, the test for it. But speculations of this kind, although they cannot avoid suggesting themselves to a reflective mind, are not likely to help us much at the present time. Some explanation sufficient to cover all the facts will probably be forthcoming one day if we only continue to observe and study the subject with logical candour from every point of view. It is curious, however, to notice the differences of interpretation and opinion regarding the history of the present epidemic. We notice in some of the Indian lay journals that they appear to be somewhat sceptical about the accuracy of the alleged origin at the late Hurdwar fair of the epidemic west-

ward. The cases which led to the breaking up of the fair and dispersion of the pilgrims were, it is asserted, very few in number, and there was no great violence in the outbreak. The course taken by the cholera this year was much the same as in 1829, 1831 and 1847, only the rate of its progress has been enormously accelerated if it had its alleged origin in March last. From the Indian point of view it is urged that it is by the overland route and not by the sea route that Europe is most susceptible to cholera invasions and that quarantine on shipping from Bombay and India is a measure aimed in the wrong direction.

Great activity is displayed on the Continent in efforts to stamp out or limit the spread of the disease by the prohibition or postponement of public fairs, fêtes and public gatherings; but the Czar, it is stated, while ordering General Gourko to report on the state of the cholera in Poland, has not countermanded the army manoeuvres this year. Telegrams from the Hague, Rotterdam, Antwerp, Havre and Berlin give returns of a small number of cases of cholera. The disease continues, but is decreasing at Hamburg, and it also still lingers in Paris and its suburbs, and has extended into Galicia. At New York the excitement regarding it has died out, but quarantine is rigorously maintained. The epidemic so far has gone to show that the populations of well-drained cities abundantly supplied with pure water are pretty well ensured an immunity from cholera, provided that a vigilant eye is kept upon the shipping and due precautions be taken against the sudden importation of cholera into their midst. The medical advisers of the Local Government Board in this country have formulated excellent regulations, and the port sanitary officers are to be congratulated on the success with which they have carried them out.

### CHOLERA AT HAVRE.

A very interesting contribution to the history of cholera at Havre is published in *La Normandie Médicale*, the writer being Dr. Gibert, the well-known physician and epidemiologist of that town. The first case of cholera in Havre occurred on July 14th, a second on the 28th, a third on Aug. 2nd, and two more on Aug. 4th. Thirteen more took place between the 9th and 13th, and up to this date no less than fourteen out of the eighteen persons attacked had died. After this the disease increased with rapidity and the severity was considerable. Indeed, Dr. Gibert states that of the first fifty cases received into hospital no less than forty-eight died. Between Aug. 16th and 31st 815 attacks and 255 deaths took place, and it was only with the month of September that any material diminution set in. Dr. Gibert's story only goes to Sept. 11th, and by that date a total of 1091 cases and 393 deaths had taken place in forty-two days—an amount and fatality of cholera that can best be judged of by the fact that had the population of Paris been smitten at the same rate there would have occurred in the same period 27,275 cases and 9825 deaths. The disease, as is well known, has been continued in Havre up to the present date, although at a diminishing rate, and hence the total effect of the epidemic on Havre has yet to be told. But perhaps the most interesting part of Dr. Gibert's straightforward narrative relates to the etiology of the disease. In the first place, he asserts that the introduction of the new term "diarrhée cholériforme" has had a most deplorable result from the point of view of prevention; it has, he says, been deceptive both as to the nature and severity of the disease, and in its clinical aspect it is altogether unjustifiable. Here it is that, according to his view, his Paris colleagues have fallen into a most unfortunate error. MM. Dujardin-Beaumetz, Brouardel and Proust declared the cholera around Paris to be a simple cholera on the ground that its diffusion was slow instead of rapid, and it was also announced that it was due to drinking Seine water. But not only were there many attacks—at Auber-villiers, for example—which were typical of true cholera in its worst form, but Seine water alone would not produce cholera. Contaminated waters have again and again been in maintained use, producing various ailments and diseases; but it is evident that Dr. Gibert holds to the view that, if water produces cholera, that water must have received the infection of cholera. These views coincide with the opinions we have all along expressed. From the first we contended that whatever the Paris disease might be called, it was for all etiological and preventive purposes what-

we term cholera; and though we have long known that the use of the Seine water was almost invariably associated with an excess of enteric fever in Paris, yet we were convinced that the cholera in the outskirts of Paris last May and June had not originated in the use of that water, whatever might have been the causes of its ultimate extension. Dr. Gibert takes up the argument from another point of view. He reminds his colleagues of all the attempts they have made at European conferences to set up a barrier in the East—namely, at the Suez Canal—against the westward advance of cholera; but if it be true that the consumption of water from a river which is polluted with sewage can in itself produce cholera, wherein lies the good of the eastern barrier? In short, Dr. Gibert has the courage of his opinions; those opinions coincide with the researches of modern science, and they are the only ones which free such occurrences as those in and about Paris from that which, more than any other cause, tends to obscure the true nature of the circumstances that have to be dealt with. As regards the Havre cholera, Dr. Gibert admits that its cause has remained undiscovered. Whether it was due to an unknown importation by means of travellers arriving from Russia and only suffering from the disease in a mild, but none the less infective, form may not now be ascertained. But the statement that the disease was imported from Hamburg by means of the steamship *Rugia* on Aug. 24th is altogether fallacious, for by that date 74 cholera deaths had already taken place in Havre. In point of time the reverse is far more likely—namely, that Hamburg received its cholera from Havre, where, notwithstanding Dr. Gibert's honesty, the disease was for a considerable time roused up. The narrative contained in *La Normandie Médicale* gives an excellent account of the energy which, under Dr. Gibert's advice, was displayed by way of prevention. The indigent poor inhabiting the worst dwellings were actually removed from their homes, and were housed, clothed, washed and fed pending the thorough disinfection and cleansing of their homes, and it was subsequently to the adoption of these amongst other measures that the diminution in the extent and fatality of the disease set in. In conclusion, Dr. Gibert states that the statistics of the epidemic which we have quoted fail to give a true idea of its severity, because other cases than true cholera were, for preventive purposes, included in the list of cholera attacks. But of those cases which were removed to hospital no less than 70 per cent. terminated fatally.

## THE CHOLERA IN FRANCE.

(FROM OUR SPECIAL CORRESPONDENT.)

### PRECAUTIONS ON THE FRONTIERS.

THE French Government has, it is now well known, finally abandoned all idea of establishing quarantine for travellers who enter the country by land. Instead of quarantine, a method of medical inspection and control was organised, which has been already described. I will therefore only briefly mention that everyone entering France from countries supposed to be infected passes a medical examination at the frontier, receives a sanitary passport, must have all dirty linen disinfected, and is placed under medical surveillance for five days. It was with feelings of keen curiosity that I approached the frontier station of Feignies, on the road from Brussels to Paris. When the train drew up on the platform all the doors leading to the station were carefully closed and guarded. Leading up to one door, where a gendarme stood in full uniform, a wooden balustrade had been erected, so as to enable the passengers to form a queue, as is done at a theatre, and thus prevent crowding and pushing. Railway porters examined every carriage so as to make sure that no parcels or bundles had been left in the train. As each passenger in turn approached the door guarded by the gendarme, he was asked to produce his card and to write upon it the name of the town he came from and to give in full the address of the hotel or house where he intended to stay. As soon as the door was passed the passenger found himself facing a table where two clerks were busily writing. On the left-hand side a com-

missioner of police dictated from all the passengers' cards the name and address. This was inscribed in a large book by one clerk and on a yellow card by the other clerk. The yellow card was then handed to the doctor who stood on the right-hand side of the passenger, and by whom the passenger had, it is to be presumed, been examined while these inscriptions were made. But as it does not usually take more than a few seconds to write out a name and an address, the medical examination was of the briefest. The doctor, who held a pen in his hand all the time, hastily scribbled his initials on the yellow ticket and handed it to the passenger. The passenger was now made to move on to the next room, where the porters were bringing in the luggage from the train. Thus the severest part of the ordeal was brought to an end. The only inconvenience is that some of the passengers have to wait a considerable time before they can get through; and, if they are heavily laden with bundles and parcels, this is somewhat fatiguing, as in the crowd there is no room for porters to assist. Then it must be borne in mind that if the medical examiner thinks fit he has the perfect right to detain any passenger. Fortunately no one as yet has been detained. Nevertheless the law does sanction the detention for the period of five days of any passenger who exhibits suspicious symptoms. Such symptoms, however, would have to be of a very marked character to be observed in so cursory an examination.

Having obtained my yellow card, or sanitary passport, as it is called, I was free to see after my luggage. The custom house officials, including a woman for women's clothes, showed much greater severity than usual, and caused a larger number of trunks and parcels to be opened than was the practice before the cholera epidemic. But they seemed far more concerned in preventing the smuggling of cigars than in detecting the presence of soiled linen. I was not even asked whether I had any soiled linen, but the custom house official made a very determined dive for a suspicious-looking box at the bottom of my trunk, being under the mistaken conviction of having discovered a goodly store of cheap Belgian cigars. I saw no soiled linen anywhere. Most if not all the passengers had been careful to cause their linen to be washed before starting. Whatever linen is found is taken away and disinfected by steam under pressure and forwarded to the owner by parcel post. What with the medical examination, the delivering of a sanitary passport to each traveller, and the rigour displayed by the custom officials, the delay at the frontier is from half to three-quarters of an hour longer than usual. But I fancy extra steam was put on when once the train started. In my case, when we arrived in Paris we were scarcely half an hour behind the appointed time.

On my sanitary passport I found a warning to the effect that if I did not report myself at the nearest town hall within twenty-four hours after my arrival at my destination I should, in accordance with Article 14 of the law of March 3rd, 1822, be subject (and this without the possibility of extenuating circumstances) to from three to fifteen days' imprisonment and to a fine of from five to fifty francs. It will be observed that there is no option between imprisonment and a fine, but that both fine and imprisonment are to be inflicted. Consequently I did not fail, on the morning of my arrival, to report myself at the Mairie of my district. Here my passport was stamped, and this is the proof that I duly reported myself, and therefore I need no longer fear imprisonment. But even before I had time to go to the Mairie an official had been round to my house and had inquired of the porter whether I had arrived and was in good health. Every day since this official has returned and renewed his inquiry. On being assured by the porter, or *concierra*, that I was up and about and apparently in good health the official went away satisfied. Had I failed to put in an appearance at the porter's lodge during the day he would have come up to my room to make sure that I was not suffering from cholera. This kind and polite solicitude on the part of the authorities as to the condition of my health will continue for five days, which, according to French medical opinion, is the period of cholera incubation. Assuredly this is the best of all the precautions taken. There is no harm in watching persons, so that measures of isolation and disinfection may at once be applied. So far, however, these precautions, though they necessitate considerable trouble and expense, have been taken in vain, and should be applied in the case of those who leave France rather than in that of those who enter France. The newspapers I was reading while travelling from Belgium to France recorded that there had been on the previous day three cases of cholera at Antwerp and not one at Brussels;

sea, in fact, is a great purifier; and though the sanitary conditions were forty cases in and about Paris and fifteen cases at Havre.

It was only at the end of the month of August that the decree ordering the application of the system of inspection and surveillance just described was signed. This decree was not actually put into execution before Sept. 3rd. As the first cases of cholera in Belgium occurred on Aug. 16th the French frontier remained unprotected for a good fortnight; and now that the decree is applied, from what I saw at the frontier station, it is quite certain that soiled linen can and does occasionally pass through. Thus, after all, the only real security against cholera is the internal sanitary condition of the country and not these precautions taken at the frontier. But even if no soiled linen did pass among the passengers' luggage the decree only applied to such luggage. The luggage that was not registered with the passengers, but was forwarded separately, came through without let or hindrance. Only a few days ago it was discovered that at the various railway stations of Paris there were several hundred boxes, cases and parcels that had been forwarded directly from Hamburg and other contaminated places to Paris. When claimed by the owners these boxes were handed over without any sort of sanitary precaution. Thus anyone travelling from Hamburg to Paris had only to send his luggage by goods train or by parcels express and it was delivered to him in France without undergoing any process of disinfection. One of the principal medical officers in the service of the Paris municipality, having made this discovery, hastened to inform the Premier, M. Loubet, who, as Minister of the Interior, is the highest sanitary authority in France. M. Loubet, who was not at the time at the Ministry, ultimately signed an order for all the parcels, boxes &c. that were at the stations, and which had been sent by goods and other trains, not to be delivered over to the owners, but to be opened by the owners when claimed, and all soiled linen and other suspicious objects to be taken out and disinfected. To do all this a special and novel service had to be organised at each railway and goods station. The whole was done with great rapidity, but of course a large number of boxes &c. had been delivered and introduced into Paris before this service was established. Therefore even if these measures can keep cholera out of the country, it is very certain that cholera has had ample opportunity of effecting an entrance before the measures were applied. All these incidents show how impossible it is to take thorough precautions for the exclusion of cholera. To be thorough, these examinations &c. should have been enforced on Aug. 16th, and they were only applied on Sept. 3rd. Then they only dealt with the registered luggage accompanying the passengers, whilst all luggage sent separately was allowed to pass freely.

After having neglected for too long to examine passengers' luggage a reaction in the opposite sense naturally ensued. The railway official became too keen and zealous. Thus, the other day a somewhat comic incident occurred. A large body of English tourists arrived from Homburg. They had, of course, passed the frontier without difficulty; but at the Paris railway station the officials thought they had made a terrible discovery and seized all the luggage, refusing to give up the smallest parcel. In vain the English tourists protested that they had come from a perfectly healthy country and that there was not a single case of cholera at Homburg. In vain the English tourists explained that Homburg was not the plague-stricken seaport town, but a peaceful inland watering-place; the railway official could make no distinction between Hamburg and Homburg. It was only after a great disturbance and the fortunate appearance on the scene of a medical man attached to the sanitary services, who had a better knowledge of geography, that the railway officials were made to recognise their error and restored the luggage to the English tourists.

While Paris is being thus protected from outside contamination the state of affairs within its walls has far from improved since my last visit. I have not yet had time to make many inquiries; but I have ascertained one fact, which in itself is sufficiently significant. From Aug. 1st to the 16th the municipal authorities performed 668 disinfections; from Sept. 1st to the 16th the number was no less than 1593. Of these latter disinfecting operations, 817 were due to cholera or choleric cases. In one single house where a case of cholera occurred no less than twenty-two apartments or separate tenements were disinfected. Certainly in this respect the authorities have shown the greatest energy, and no pains or expense have been spared.

Our Paris correspondent writes: "The cholera epidemic is, I am happy to announce, not making any sensible progress in this country. In Paris itself the mean daily mortality from this disease has descended from 32, the figure at which it stood for the first fortnight of September, to 12 for the second fortnight. Since the beginning of the outbreak at Havre there have been up to this date (Sept. 20th) 1197 cases and 438 deaths. The directors of the Paris hospitals are required to have the water consumed by the patients analysed, both before and after filtering, by the resident pharmacist. All nurses who succumb while on duty to cholera are to be buried free of expense at Père Lachaise, and such deaths are to be reported immediately to the Director of the Assistance Publique, the Prefect of the Seine and the President of the Municipal Council. The cholera wards at the Necker Hospital have been, since the beginning of the outbreak, under the charge of Dr. Peter. At yesterday's sitting of the Académie de Médecine this veteran disciple of Trousseau communicated the statistics of his cholera patients. He stated that from May to the 18th inst. 118 cases (including 10 of simple diarrhoea) came under his observation. Of these, 44 died, the mortality thus being 40.8 per cent. Thirty-five cases were closely watched, and it was seen that they could be split up into several categories. Thus in 4 the stools were simply diarrhoeic, in 6 they were simply bilious, in 14 they were bilious and contained besides rice-like particles, in 6 the stools were rice-water in appearance, and in 2 they were dysenteric; in 3 cases the pure comma bacillus was found, in 9 the pure bacterium coli, in 1 the comma bacillus of Finkler-Prior, in 4 this latter micro-organism was associated with the bacterium coli, and in 1 the bacterium coli was found with a diplococcus. No experiments were made with the comma bacillus, but the bacterium coli killed rabbits in from fifteen to fifty-two hours with all the symptoms of cholera. Rabbits were refractory to the diplococcus. Of 10 fatal cases, 4 had rice-water stools and 6 bilious stools with or without rice-like deposit. The total mortality as thus analysed stands: 66 per cent in cases with rice-water stools; 30 per cent in cases with bilious stools; 0 per cent in cases with common diarrhoeic stools. One of the characteristics of the present outbreak is that many patients die during the period of reaction, all vomiting and diarrhoea having ceased and cyanosis and algidity being absent. The hot weather seems to have had a malign influence on the mortality. Thus from the 22nd to the 30th of August, the temperature being low, 16 out of 27 patients succumbed. The temperature having risen on the 1st of September, 6 out of 7 cases died. As regards contagion, he considers cholera as less contagious than typhoid fever. Dr. Peter refers to the panic-stricken authorities of New York, whose stringent measures of precaution are, according to him, contrary to the dictates of common sense. As to treatment, he combats the premonitory diarrhoea with opium, and avows himself—forgive the Hibernianism—a warm partisan of the spinal ice-bag, which he finds relieves the cramps very promptly. Friction, injections of ether and caffeine, alcohol and mustard foot-baths complete Dr. Peter's armamentarium. He concluded his paper by refusing to acknowledge the existence of the varieties of cholera. This view was immediately opposed by Dr. Brouardel, who discovers such points of divergence between the Paris epidemic and true Asiatic cholera that he cannot admit their identity. The Paris form is sporadic, whilst the true Indian variety is epidemic. He points out that clinical and bacteriological observations cannot solve the problem. He rebuts Dr. Peter's assertion that cholera is less contagious than typhoid fever."

## THE CHOLERA IN BELGIUM.

(FROM OUR SPECIAL CORRESPONDENT.)

### THE DANGERS OF INLAND NAVIGATION.

WHILE great precautions are taken at seaports to prevent the importation of cholera by some sailing ship, there is a tendency to overlook the dangers of inland navigation. Yet it only requires a moment's reflection to show that a canal may be far more dangerous than the sea or a river. The

ditions that prevail on board seagoing ships are often far from perfect, there is more space and better air than on board a barge in a canal. Bad sanitation on board ship or barge is an important factor in the spread of cholera. The epidemic selects at least its first victims among those who sleep in badly ventilated, dark rooms. Though in the course of time the scourge may reach all classes of society, those who live in the worst sanitary conditions are always the first to suffer. When I mooted this phase of the question to members of the Scheldt Sanitary Commission, they urged there were special reasons to be watchful over those who travelled by water. There was always ventilation in a railway carriage. The doors were constantly opened. A ship had to be made air and water tight. This was not the case with a railway carriage. The rapid motion of the train forced the air through a thousand small fissures, so that even if the travellers were foolish enough to shut all the windows and ventilators, still there was some air. This could not be said of the steerage and the sailors' quarters on board ship. Whatever care may be taken to ventilate the saloons the fore-castle is too often neglected. Thus the sailors, by the fact that they sleep in dark, badly ventilated and often very dirty cabins, are more particularly susceptible to the danger of contracting cholera. These arguments were adduced as a sort of explanation of the contrast afforded between the severity of the quarantine regulations imposed at Doël-on-Scheldt, which I described last week, and the ease with which travellers by railway could enter Belgium. A traveller starting from Hamburg by sea would not be allowed to land at Antwerp till seven days after his departure. The same traveller, if he took the railway, could reach Antwerp in twelve hours. Of course such a traveller would be detained if just at the very moment he was passing the medical examination at the frontier he fell ill; otherwise there is no obstacle and no delay worth mentioning in the intercourse by land between Antwerp and Hamburg. Many a panic has been created in various business offices at Antwerp by the sudden arrival direct from Hamburg of some customer or business agent. Several merchants complained in my presence at having been compelled to receive and entertain customers from Hamburg whose presence at Antwerp, though usually very welcome, was scarcely desirable under existing circumstances. Certainly a prolonged habitation of the dirty, dark, ill-ventilated and crowded fore-castle of a seagoing ship is more likely to facilitate the development of cholera than a brief sojourn in a railway carriage; but this difference is not so great as to justify seven days' quarantine against travellers by sea and no quarantine at all against travellers by train.

Whatever may be said concerning insanitary conditions on board ship can be said with even greater force of the barges that glide along the stagnant and often foul water of a canal. The cabins inhabited by the bargemen and their families are extremely small, and if they appear to be clean this "cleanliness" is due to washing with the dirty water taken from the canal. There are no strong sea winds to send down gusts of purifying air into these cabins, and to impart health and vigour to those who are on deck. Also the character of the cargo taken on board a barge is often more foul than that received on board a ship. For instance, there are some very important manufactories of human guano in Belgium, which employ a fleet of barges that travel in all directions to collect the contents of cesspools. A year or so ago I saw some of these barges at Calais, where they came to fetch the contents of the cesspools which abound in that town. These barges would have to travel several days on canals to reach the guano factory in Belgium.

One very important grievance was pointed out to me by M. Vandervelde, the chemist of the Scheldt Sanitary Commission. There are actually in the docks of Antwerp some two or three hundred barges loaded with grain. It has become a regular practice to use barges as dépôts for grain. A corn merchant buys a cargo of grain which he is not able to sell at once. To put this grain into dock would cost a considerable sum of money, and there are difficulties in the way of sending labourers to stir this grain when in dock. The corn merchant therefore hires a barge, and when once in the barge the grain is ready to be delivered as soon as a purchaser is found. But it often happens that a considerable time elapses before the grain is sold. In the meanwhile bilge-water accumulates in the barge. The bilge cannot be pumped out for that would wet and spoil the grain. Then there is an invasion of rats and mice, which adds to the foulness of the barge, and fermentation sets in. Nevertheless the barge remains stationary in the docks, and the barge-

man and his family continue sleeping on board, breathing throughout the night the foul emanations of the dead rats, the fermenting bilge water &c. It has already been noticed that cholera is especially prevalent among bargemen, but M. Vandervelde is about to prepare statistics which will, he believes, show that, among the bargemen suffering from cholera, an exceptionally large proportion belong to the barges that have been made to serve as dépôts of grain.

Early in the history of the present epidemic it was found that bargemen were conveying the cholera from town to town. The sanitary authorities of Brussels were, I believe, the first to appoint medical inspectors to visit all the barges that came to Brussels. In the suburbs at Lacken and other places there had been cases of cholera on board barges coming from Antwerp. The other day a somewhat dramatic incident occurred. Dr. Huart and Dr. Matthys, who were inspecting the barges on their arrival at Brussels, found a bargeman suffering from cholera. The ambulance carriage was immediately on the spot, but a panic prevailed, and no one would help to take the bargeman out of the cabin and off his boat. The two doctors whose names I have mentioned had to perform this dangerous and difficult task themselves. They carried the unfortunate bargeman in their arms up the ladder from his cabin and on to the shore, where they soon reached the carriage. The bargeman's wife was also seized with terror; she completely lost her presence of mind, took all her husband's soiled clothes and threw them into the canal. It was with great difficulty and after a considerable loss of time that these various objects were taken out of the water. Together with the bedding used by the patient these clothes were burnt, but who shall say that they had not already contaminated the water of the canal. Apart from this peculiar and exceptional case, it is well known that the dejecta of the bargemen, whether suffering from cholera or not, are thrown into the canal. It is equally notorious that the bargemen not only wash their barges with the water from the canals, but also, and not unfrequently, drink this water. Thus, if statistics were forthcoming as to all the cases of cholera which have occurred in Belgium, it would be found that a very large proportion of the cases have occurred among bargemen and their families. It will also be found that at Malines, at Bornheim, and a number of other places, the cholera was brought to these towns by barges coming from Antwerp. So pressing has this danger become that a new sanitary post has been established at Vilbrooke, on the canal midway between Brussels and Malines. It is all the more necessary to protect the town and district of Vilbrooke as this locality suffered most severely during the last cholera epidemic. While the deaths from cholera at Brussels amounted in 1866 to 20 per 1000 of the population they were equal to 45 per 1000 at Vilbrooke.

At Brussels very severe measures are taken against the canal barges. On the slightest suspicion of illness the cabins are disinfected by the burning of sulphur. Notices are served on the bargemen urging them not to drink the water of the canal. At Antwerp a large number of barges have been disinfected as a precautionary measure, and efforts have been made to provide pure drinking water to the bargemen. Still, the bargemen constitute a rough, ignorant population and it is very difficult to make them understand the advantage of all these measures. The more the matter is studied the more necessary it seems to watch over the canal populations. The general public hears and knows a great deal more about ships and railways than about barges and canals, and there is consequently a tendency to overlook the latter. The development of the epidemic so far clearly shows that such neglect would be a fatal mistake, and that cholera may travel by canals and barges as surely if not as rapidly as by railway and ocean-going steamships.

#### CHOLERA IN GERMANY.

Our own correspondent, writing from Berlin, states that the numbers of the cholera cases and deaths reported in Hamburg on the 9th inst. were 350 and 150, on the 10th 213 and 113, on the 11th 390 and 175, on the 12th 333 and 142, on the 13th 344 and 148, on the 14th 283 and 108, on the 15th 306 and 128, and on the 16th 276 and 136. The number of cases in Hamburg down to Sept. 10th is authentically given as 13,238 and that of deaths 5805—that is, 44 per cent. of the cases ended fatally, a very favourable proportion when compared with the mortality

in former cholera epidemics in Berlin, which fluctuated between 60 and 67. The number of cases in proportion to the population of Hamburg is about 1 in 46, that of deaths 1 in 105. The corresponding figures in the Berlin epidemics of 1837 and 1849 were 74 and 113. The continuance of the epidemic will of course make the comparison still less favourable for Hamburg. Professor Koch went to Hamburg again on the 14th and was present at the meetings of the Cholera Commission there next day. On the 16th the Commission resolved to sink Abyssinian wells in many parts of the city and its environs. Dr. Koch returned to Berlin on the 16th, but declared his willingness to attend the meetings of the Commission at any time. The Hamburger Börsenhalle states that he and Privy Councillor Köhler, director of the Imperial Office of Health, inspected the hospitals and barracks, and all the arrangements for the transport, treatment and care of the patients and for dealing with the epidemic, and that Dr. Koch expressed his admiration of them in the highest terms. Such perfection, he said, had never been attained before. An Imperial Commissioner has been appointed for the hygienic supervision of the basin of the Elbe, and has divided it into eight districts, with an army doctor at the head of each. His name is Baron Richthofen. The Emperor has empowered the commanders of army corps to diminish the sentinel service, to forbid funeral parades, and to reinforce the staffs of the military hospitals from the reserve. In the Moabit Hospital, belonging to the city of Berlin, to which the few sporadic cases that have occurred here have been taken, special arrangements have been made for the disinfecting of the excreta. The latter are mixed with a 5 per cent. solution of permanganate of potash and then boiled for from four to ten minutes.

A correspondent writes from Hamburg: "There can be no doubt that the cholera in Hamburg was imported from Russia, but the exact source has not been traced and cannot now be found. It commenced on Aug. 16th, but it was not till 1 p.m. on Aug. 22nd that the foreign consuls were informed that cholera existed in the city, though 58 deaths had previously occurred; thus ships which may have been freighted with this deadly scourge were sent all over the world with clean bills of health. The most fatal days of the epidemic were Aug. 26th with 456 deaths, the 29th with 484, and Sept. 1st with 478. Up to the present time there have been probably 7000 deaths. Though considerable confusion occurred at first, now the sanitary stations, the disinfecting stations, the ambulance arrangements and the depôts for the dead are in perfect function. The cholera is all over the town, and it is reckoned that 28,000 citizens have left the place. The cholera is of a fatal character, at least 50 per cent. dying. It is of a type of disease not unusual in Europe, but not so very frequently seen in the East. The diarrhoea and premonitory symptoms are severe, rapidly followed by collapse, in which death usually occurs if the disease is fatal; but should that not happen, the reaction is comparatively mild, the typhoid fever condition not severe, and any high febrile state very rare indeed. Albuminuria is fairly common but by no means universal. Nothing worthy of remark is to be noticed in the treatment, the mild cases recovering without any complication, and those of a severe type dying rapidly in collapse, no treatment apparently making much difference. The evidence derived from the type of disease is strongly confirmatory of an importation through Russia. It is most earnestly to be hoped that the inhabitants of Hamburg will be thoroughly roused to the danger of drinking Elbe water that has gone through a mere farce of filtration."

#### CHOLERA IN AUSTRIA.

Our Vienna correspondent writes:—"The cholera has now made its appearance on Austrian territory, at Cracow. The first case is said to have occurred as early as on Sept. 8th, at Podgorze. Soon three other cases followed in the same quarter. Podgorze is a suburb of Cracow, separated from this town by the Vistula river, which is there spanned by a bridge. On Sept. 9th a case of suspected cholera had been admitted into the Cracow Hospital of the Samaritan Brothers (Barmherzige Brüder), a Catholic order of monks devoted to nursing and treating the sick. On Sept. 11th there was much talk about the occurrence of cholera cases in the town of Cracow, and similar rumours were also heard regarding Vienna. After a meeting of the highest medical council, held on Sept. 10th in Vienna,

nothing was set forth by the official organ of the Council, *Oesterreichisches Sanitätswesen*, and on the 15th inst. it stated that "no case of cholera had occurred in Austria up to Sept. 13th." The public were much surprised by an official statement of the probable outbreak of the cholera made by the official gazette on Sept. 17th, on which day also the Professor of Pathological Anatomy of Vienna (Professor Weichselbaum) was sent by Government to Cracow to make a bacteriological investigation. Precautions were thereupon taken to prevent the further spreading of the disease. In other parts of Austria the progress of the disease is watched with the greatest anxiety. Cracow itself, and especially its suburbs, Kasimir and Podgorze, are in a very bad sanitary condition. It contains a poor, filthy population, bad drinking water partly taken from the river, and an inferior system of treating the sewage. The province of Galizia, in which Cracow is one of the principal towns, with its 6,600,000 inhabitants, has only seventy-two hospitals, with 4257 beds. Most of the villages are too poor to build new hospitals. Even the number of physicians, especially in the rural districts, is too small in ordinary times to secure proper treatment of the sick people, and in the time of an epidemic a great number of physicians from the other provinces will have to be sent to Galizia.

"The circumstances under which the outbreak of cholera at Cracow occurred seem to teach the same lesson as in the case of Hamburg. In both towns the report of the outbreak of the disease has been considerably delayed by the claims of modern bacteriology, according to which the diagnosis of cholera Asiatica is only allowed to be made if the comma bacillus is stated by microscopic examination and by subsequent cultures to have been present. But regarding the cultures there seems to exist great difficulties. I believe that especially one point is easily to be overlooked by those engaged in such investigations—i.e., it is not to be expected that a culture could be easily obtained of such a micro-organism as the comma bacillus, whose vitality is so immensely lowered by most chemical bodies as soon as the patient has already undergone any medical treatment. The matter for the cultures should, if possible, be obtained from the dejections or vomited liquids before any medicine has been administered.

"By the strict system of quarantine maintained in this country the trade and the industry have already been interfered with. In the industrial districts of Bohemia and Moravia production has to be restricted on account of the want of raw materials which were imported from Germany. It is easy to understand that it is not possible to keep the population of the empire under good sanitary conditions at a yearly rate of expenditure of two and a half kreutzers, a halfpenny per head of population, and that is one reason why cholera phobia is now so prevalent among the people. Even now, in the time of imminent danger, parsimony prevails so much over common sense and humanity that local authorities—as for instance, the municipal board of Vienna—are disputing with the Government regarding the duty of erecting cholera hospitals at Vienna. Nor is it less interesting to learn that the Government is asking the hospital physicians to enter cholera hospitals, promising a salary of sixty-two florins (£5) monthly with board and lodging."

## THE SANITARY CONGRESS, PORTSMOUTH.

### PAPERS AND SECTIONAL WORK.

In the absence of Dr. J. Wright Mason, Medical Officer of Health for Hull, Dr. Groves read a paper by the former on the Sanitary Influences of Harbours and Exposed Fore-shores. He advocated the perfect sanitation of our first line of defence and mentioned the special risk of zymotic invasion by way of those ports in most constant and direct communication with the Continent.

Dr. Dawson Williams contributed a paper on the Route of the Cholera in 1892, and traced the disease from the north-west frontier of India, through Afghanistan, and along the Transcaspian railway, across the Caspian to Baku, the centre of European infection.

Dr. Lane Nottter pointed out that the strength of our first chain of defence was measured by that of its weakest link, and he asked if anyone could say what was being done in the smaller ports and along the coast generally.—

Dr. Thresh said that in the small port sanitary authority of Malden, in Essex, a hospital tent had been erected, and along the whole coast the coastguard officers had been instructed with whom to communicate should a case of cholera or choleraic diarrhoea come to their knowledge.—A Member remarked that the paper scarcely justified its title.—Dr. Lane Notter considered that yellow fever originated in slave ships, though the conditions favourable for its continued existence seemed to be associated with exposed foreshores.—Professor Cayley pointed out that in several recent epidemics of yellow fever there was no association with the slave trade.—Dr. Groves stated that cholera had often been said to follow the course of rivers. This had been observed in this country. When a young man he had assisted to investigate the cause of the outbreak in 1866, and showed how the *fons et origo mali* had been found to be pollution of the water supplied to a portion of the East-end of London.

A vote of thanks to Dr. Lane Notter, who had presided at all the meetings of the Section, was proposed by Dr. Thresh and seconded by Dr. Sandall.

In Section 2 Mr. James Lemon, the President, gave an interesting address on Engineering and Architecture. He gave the medical profession credit for having called the sanitary engineer into existence. He criticised adversely the metropolitan scale of drainage, and said that the question of dealing with rainfall should be determined by local considerations. He pointed out the care necessary in the management of sea outfalls, especially as regards the determination of the force and direction of currents, before discharging crude sewage. He also remarked upon the folly of insufficient drain ventilation, and said the ideal drain was an open one in the centre of the street, were it practicable. Finally, Mr. Lemon sketched the points to be borne in mind by the sanitary architect (a term of his own coinage) in constructing a model house.

Papers were read by Mr. Hubert L. Terry on the Smoke Clauses of the Public Health Act, 1875; by Mr. Hepworth Collins on the Pollution of Rivers and Canals by Manufacturing and Industrial Operations; by Mr. W. R. Maguire on the Causes and Prevention of Typhoid Fever; by Dr. H. Kenwood on Drain and Soil-pipe Ventilation; and by Mr. Henry Law on Apparatus for Softening Water.

#### *Visit to Haslar Hospital.*

During the afternoon about twenty medical members of the Institute visited Haslar Hospital, being conveyed across the harbour in a special launch. They were conducted over the building by Inspectors-General E. T. Mortimer and Macdonald. The hospital was erected about 150 years ago, and has had as many as 2000 patients within its walls at one time. At present there are about 500, but many of them are aged pensioners who were transferred from Greenwich. The complicated structure, absence of any artificial mode of ventilation &c. prove that it does not reach the level of modern requirements in an institution of this character. After inspecting the museum, which contains a large number of specimens of interest to the comparative anatomist, and which possibly would be of much greater service if properly catalogued and suitably housed in a more accessible situation, the visitors partook of afternoon tea and returned to Portsmouth. The weather was perfect and the trip a most enjoyable one.

#### *The Annual Dinner.*

The Congress dinner was held in the evening in the Mayor's banquetting-room at the Town Hall. Sir Charles Cameron was in the chair, and there were present the Mayor of Portsmouth (T. Scott Foster, Esq.), the ex-Mayor (Sir W. Pink) and a distinguished company. In proposing the loyal toasts, the President read a telegram from H. R. H. the Duke of Connaught regretting his inability to be present. Appropriate recognition was taken of the "Army, Navy and Reserve Forces," "The Mayor and Corporation of Portsmouth," "The President and Officers of the Congress," "The Borough Members," "The Sanitary Institute" and its "Local Secretaries," and finally "The Health of the Ladies" was proposed and duly honoured.

#### *Chemical History of the Air.*

On Friday, the 16th inst., Dr. W. J. Russell, F.R.S., the President, gave an address in Section 2 on the Chemical History of the Air, and traced rapidly and instructively the gradual evolution of facts and opinions in connexion with his subject from the days of Hero of Alexandria, "whoever he may have been," to the present time, giving a due meed of praise to pioneers such as Van Helmont, Hook, Boyle and Mayan, and

emphasising the great services of Bunsen in this matter. He gave the mean result of the quantitative analysis of air as regards oxygen to be 20.90 per cent., and stated that at the present time probably the most interesting results to be derived from the accurate determination of the oxygen in the air are in relation to this point, the using up of the oxygen, for it is difficult to suppose that two or three hundredths of a per cent. of oxygen can in itself produce any appreciable effect either on respiration or combustion. Ozone, he stated, is probably always present in normal air, but unfortunately we have no accurate method of determining its presence. Dr. Russell inclined to believe its formation was probably due to electrical action and directly or indirectly to evaporation. He then dealt with the question of solids suspended in the air, and said that the great Krakatoa eruption of 1883 had shown how dust on a large scale may be ejected into our atmosphere, and how persistently it may abide there and circulate round and round the globe.

A vote of thanks was passed to the President for his able paper.

#### *Chalk Area and the Water-supply.*

Mr. W. Whitaker, F.R.S. &c., read a paper on Maps showing the Area of Chalk suitable for Water-supply in the Central and Eastern Parts of the London Basin, and stated that the whole area coloured as chalk was not available as a gathering ground, and described the following chalk formations in the order of their permeability—namely, bare chalk, chalk covered by permeable beds, chalk protected by beds of mixed or of varying character, and chalk protected by impermeable beds.

#### *Sewage Treatment.*

Mr. C. H. Cooper then read a paper on Sewage Treatment.—The Hon. F. A. Rollo Russell discoursed on Exhalation of Vapour from the Earth, and, from a series of interesting experiments, drew conclusions the practical lessons taught by which were the importance of securing an impervious flooring and ventilation in houses and tents, of paving in towns, of avoiding "made soils" and the vicinity of graveyards, of drainage of damp and organically polluted soils, of widely separating cesspools from wells, and of preventing the exposure of articles of food and drink to night air near the ground.

#### *Entomology.*

Mr. T. B. Goodall, F.R.C.V.S., read a thoughtful and philosophic paper on Entomology as a Sanitary Science, and, sketching the life-history of the drone fly and the gnat, showed how usefully these myriads of "scavengers of nature" aided sanitation by the consumption of putrefactive matter.

#### *Organic Matter.*

Mr. W. C. Young contributed a paper on the Determination of dissolved Organic Matter in Water, and described a process which gave satisfactory results, and which was first introduced in a paper by the author before the Society of Chemical Industry in November, 1891. The process, he stated, was extremely simple in practice, required little personal attention, and was completed within four hours.

#### *The Purity of Stable Air.*

Veterinary Captain F. Smith, M.R.C.V.S., then read a paper on a Method of determining the Purity of Stable Air by a Comparison of the Temperature within and without the Building. "When we remember that the warming of stable air is derived from the bodies of the animals which live in it we can understand the *rationale* of the observation."

#### *Excursions.*

On Saturday two excursions took place, one to the New Forest and the other to the Isle of Wight. Neither was so well attended as had been anticipated, but the weather being perfect, both were completely successful.

#### *Exhibits.*

At the Health Exhibition held in connexion with the Sanitary Congress at Portsmouth, Messrs. Humphreys' Iron Isolation Hospital for Infectious Diseases attracted much interest, a special feature of the exhibit being the presence of a few children from the Portsmouth Hospital and a complete staff of nurses. These hospitals are more sanitary than hastily constructed brick buildings, and while it is possible to erect them in a few days, they are capable of lasting forty or fifty years.

A medal has been awarded to Messrs. Burroughs, Wellcome and Co. for their exhibition of medicine chests at the Portsmouth Health Exhibition, and a certificate for Kepler's Extract of Malt.

## A PLEASURE CRUISE.

(FROM A HOLIDAY CORRESPONDENT.)

THE latest development of the holiday is the pleasure cruise and there can be little doubt that if those who are interested in shipping industries adopt an intelligent and spirited policy this form of holiday-making is destined to increase. A reference to the advertising columns of any daily paper will show that already there is a fair choice of cruises for selection by those who like to take their holidays upon the great waters, and the time is within measurable distance when the whole world will be, so to speak, at the feet of the pleasure-seeker. The luxury of a pleasure cruise was formerly the exclusive privilege of millionaires, who could afford to keep vessels of their own, but by coöperation persons of comparatively modest means are now enabled to go whithersoever they will in greater comfort and greater safety than the wealthy owner of his own pleasure yacht.

A pleasure cruise has certain obvious advantages over other forms of travelling which make it a very desirable kind of holiday for those who are seeking repose after harassing professional duties, or for convalescents who wish to completely re-establish their health after an attack of acute illness. From the point of view of "change" nothing can be more effectual than a voyage which brings change of air, change of scene, change of food, change of companionship, change of daily routine.

The pleasure cruise enables the voyager to see a great deal without the daily worry which attends ordinary travelling. The packing, and unpacking, the slavery of a relentless punctuality and the fretting restraint of the *sallas d'attente*, the indifference of landlords who have more guests than chambers, and the tyranny of Ober-kellners under analogous circumstances, have none of them any necessary place in the well-managed sea voyage. Then again the air is pure and uncontaminated and has that peculiar quality of "freshness" concerning which our noses never make a mistake, although the chemist can tell us little concerning it. On the deck of a ship the traveller is sure of inhaling air of maximum purity, and the difference between sea air and land air is never better appreciated than on returning to the ship after a summer's day spent in investigating the lions of some maritime town. Apart from the initial purity of sea air, there is the most important fact that it is constantly being changed. If there be a breeze anywhere it is felt on shipboard, and if the ship be under way the air is renewed independently. It is true that between decks, and especially in foul weather when the scuttles are closed, the air of a ship may be the reverse of fresh, and it is probable that the fore-castle of a ship is of all places that in which may be found the smell of humanity in a state of maximum concentration. The purity of the deck seems, however, to compensate for the foulness of even the fore-castle, as the hard, ruddy look of the sailors tells clearly enough; and it can only happen very occasionally on a pleasure cruise that it is impossible to get on deck. On board ship the pleasure seeker is at least free from that bugbear of modern travel and monster hotels—the sewage difficulty, for every form of refuse is cast directly into the sea; and in no well regulated ship ought it to be possible to contract filth disease of any kind. The observant traveller, especially if he be a sanitarian, cannot fail to be struck by the enormous amount of refuse matter which is constantly being cast forth from a big ship into the ocean. Cinders, kitchen waste, packing cases, tins, "empties" &c. constitute the incessant "droppings" of an ocean steamer and enable him to understand the foulness of harbours and the serious nature of the houseboat question as it affects the Thames. It is of course highly advisable that organic refuse and litter should not be suffered to remain on board ship to encourage putrefaction and increase the danger of fire; but in point of view of the fact that a large proportion of what is thrown overboard is combustible, it seems to be rather a thriftless course not to make use of such combustible matter for raising steam.

There are certain points connected with a sea voyage which medical men who recommend such a course to their patients will do well to bear in mind. In the first place it is worse than useless to recommend a voyage to anyone who is not at least a tolerable sailor. There are those who become giddy and nauseated with the least move-

ment of the ship and to such as these a voyage is mere labour and sorrow without any compensating advantages of any kind. To those who can tolerate the movement of a ship the sea air acts as a vigorous tonic and causes a marked increase of appetite. This constitutes one of the dangers of a sea voyage, because with the increase of food there is a decrease of exercise and often an increase of sleep. There is often also a tendency to constipation, and thus the normal balance between intake and output is disturbed and biliousness results. Hence it often happens that during the first week at sea landmen deteriorate in appearance and the complexion shows some pallor, or sallowness, or duskiness. This condition of things is to be avoided by the judicious use of laxatives, and no one should ever embark without being provided with such laxatives as they have found by experience most serviceable. It is common to hear the remark that "sea air is too strong for me," and I think the meaning of such a phrase is that the increase of appetite and assimilation is not compensated by increase of work or increased excretion by the bowels. After the initial disturbance compensation is soon established, metabolism apparently proceeds with great vigour, and ruddy cheeks and increasing weight must be taken as the surest evidence of the benefit which the traveller is getting from the change. It would be interesting to learn with what frequency gouty people suffer from a paroxysm during the early days of a voyage. On theoretical grounds such an occurrence might be looked for; but such an accident is not very frequently heard of, and my experience at sea, which has been considerable, does not supply me with many instances.

Another precaution which it is necessary to observe at sea is to wear rather warm clothes. The deck of a ship in motion is usually colder than the shores of the same latitude, and it is customary to keep an awning continually spread to keep off not only the rays of the sun, but sooty and other particles which may escape from the funnel. This awning, useful as it is, produces a considerable draught and necessitates the provision of rather warm clothing. The mid-day sun is occasionally very powerful, but after sunset chilliness may be the predominating feature of the weather, and as the evenings are spent upon deck and in the fresh air, it is always advisable for the traveller to considerably modify his evening attire.

In the selection of a pleasure cruise the season of the year must assert its influence. The Mediterranean is perhaps the most enjoyable and most interesting cruising ground, studded as it is with places made memorable by historic events, but the Mediterranean is always too hot during the summer months and liable to be more or less unwholesome. Those who wish to take their autumn holiday on shipboard should not go to latitudes which are materially south of the British Islands. The choice of a cruising ground for the late summer thus becomes rather restricted, but the beauties of the coasts of England, Scotland, Ireland, Norway and the Baltic are so great and so varied that it would take many months of continuous voyaging to exhaust them.

My experience has been of late gained upon one of the ships of the Orient Company's well-known fleet, and the cruising ground has been the fjords of Norway and places adjacent to them. A few details of the cruise may not be unacceptable. In selecting a boat it is of course advisable to choose a big one, for, *ceteris paribus*, the comfort will be proportioned to the size of the ship. The fjords of Norway are so deep that vessels of the largest tonnage are able to penetrate to the extremities of most of them and to anchor close to the shore, so that there are no drawbacks in large vessels, and these have obviously great advantages for the transits of the open sea. The cabins of the vessel I travelled in, as arranged for these cruises, contain, none of them, more than two berths, so that if the traveller be accompanied by a friend he is secure against the intrusion of a stranger. By paying a fare and a half the single traveller can secure two berths, but this is a luxury which is not within reach of all. It should, however, be found possible to give to every traveller practical privacy without increasing the cubic space allotted to each. I remember seeing a common lodging-house in Glasgow where the beds were arranged in bunks as on board ship; and by the very simple plan of giving access to the top and bottom bunk from opposite sides privacy was secured to the occupant of each, and the confusion of articles of clothing, which is almost inevitable under existing arrangements, was avoided. The ingenious naval architects of the Clyde should visit this establishment when designing a ship intended to be used

solely and entirely for pleasure cruises, for it is certain that if the practical privacy of each traveller could be secured without additional expense the popularity of pleasure cruises would materially increase.

A word of praise must be found for the food, the cleanliness of the ship and the ample supply of clean table and bed linen which was provided, and also for the service and the general management of the steward's department which was all that could be desired. These matters are, it need not be said, of the greatest importance, and no cruise can really be pleasurable unless they receive due attention. It may be well to give a word warning to the effect that the little details upon which our happiness so much depends all cost money, and it is absurd for the traveller to expect comforts and luxuries without paying for them. A voyage such, as the one in question, costs, in one of the best cabins, inclusive of the necessary incidentals, about £2 a day, and although the sum in these days of cheap excursions is not small, it serves to keep away the crush and enables the company to perform their part of the contract with absolute thoroughness. Nobody who has not tried it knows the discomfort, not to say danger, of an overcrowded ship, where the obtaining of daily necessities means a constant struggle. My advice to intending pleasure cruisers is to select a first-rate ship, owned by persons of repute who have a character to lose, and to be ready to pay a fair sum for thoroughly good accommodation. The daily life on board the boat by which I travelled began with a cup of tea and a biscuit brought by the steward at 7 A.M. or earlier, and this was followed by a refreshing salt-water bath and a rub which set one all aglow. After the toilet a walk on deck, and at 8.30 breakfast, at which meal many of the younger men were ready (in the phraseology of the day) to "tackle" the *menu* of porridge, fish, cutlets, bacon, eggs, cold meats, preserves and fruit. After breakfast the time till the luncheon hour was spent upon deck, gossiping, reading or playing deck games. Between luncheon and dinner the hours were devoted to similar forms of busy idleness, with an interval for afternoon tea, a ceremony at which nobody was absent. After dinner there was generally a dance upon deck to the strains of an excellent band.

It is not necessary to give the details of our cruise or to descant on all the objects of interest and beauty which are to be met with in the towns and fiords of Norway; suffice it to say that dulness was impossible, and that our voyage of twenty-five days came too quickly to an end. A life of relaxation remote from the worry of that post-office cataract, which is the bane of modern existence; a life of gentle exercise and amusement in the purest air obtainable; a life in which none of us objected to take that full complement of sleep which our old adage accords only to the fool; such a life can be productive of but one result—a result which was plainly apparent in the majority by increase of weight, rounded cheeks, a ruddy colour and a bright eye, with a power of laughing at trifles which a month previously would have merely roused a half contemptuous smile—these were the characteristics of our party when we landed, albeit that it was with regret that we exchanged the pleasure ship for the galley, where (as we but too well knew) a certain oar and chain were awaiting our return.

## CONGRESS OF OBSTETRICS AND GYNÆCOLOGY AT BRUSSELS.

(FROM A CORRESPONDENT.)

### *Thursday's Proceedings.*

IN my last letter I gave a report of the proceedings up to Wednesday afternoon. The President (Dr. Kufferath) gave a dinner at the Hôtel Mengelle to about seventy or eighty members of the Congress. It was marked by being a good dinner and the commendable shortness and cordiality of the after-dinner speeches.

On Thursday morning I again visited Dr. Jacobi's hospital to see Professor Sünger operate on a case of so-called cystocele and rectocele. He first of all marked a central line down the front vaginal wall, dissected off a flap of about a finger's breadth on each side, and, cutting them off, stitched the gap up with fine silk sutures. He then drew up the uterus, and with a finger in the rectum cut a line along the posterior vaginal wall right down to the edge of the fourchette, and

dissected off similar flaps on either side, making a transverse cut along the boundary line of the vagina and vulva. He then dissected off a semilunar patch round the posterior fourchette and continued a slight nick down on the perineum. He put in some twenty fine silk sutures till he came outside the vagina, finishing with four silver wire sutures. These operations are all done at eight o'clock nominally.

At two o'clock the Congress met to hear Dr. Segond's paper on the Treatment of Pelvic Suppuration. After him the following spoke: Professor Péan (Paris), Dr. Willems (Ghent), Dr. Travers (London), in favour of abdominal operation; Dr. Jacobs (Brussels), who thought that Dr. Segond's operation should be tried as offering the best results; Professor Goubaroff (Moscow), and M. Richelot (Paris); who contended that the abdominal operation was more difficult, whereas in hysterectomy by morcellement each stage was more easily seen; also that there was even occasionally secondary hæmorrhage, showing that the uterus remained active even after the removal of tubes and ovaries, but if the uterus were removed the ovaries became inactive. Professor Sünger (Leipzig) was of opinion that Péan's operation should be exceptional. Dr. More Madden (Dublin) drew the distinction between intra-peritoneal and extra-peritoneal suppuration, saying that of old the treatment of pelvic cellulitis, which was mainly puerperal, was to leave it to nature and the cases generally got well; that in the light of modern research intra-peritoneal suppuration should be treated by abdominal section and extra-peritoneal by aspiration. M. Goulliond (Lyons) advocated puncture and draining; Professor Picheoni (Paris), Professor Delgénérière (Mans), Professor Vuillet (Geneva) puncture after careful examination. M. Walton (Brussels), M. Doyen (Rheims), M. Rouffart (Brussels), M. Duret (Lille), M. Tournay (Brussels), M. Lebec (Paris) M. Deghilage (Mons), and M. Félix (Brussels) spoke; Dr. Heywood Smith (London) agreed with Dr. More Madden in dividing pelvic suppuration into intra-peritoneal and subperitoneal. He maintained that in abdominal section the abscess could be more carefully examined and treated; he objected to Péan's operation as necessitating either the leaving of the uterine adnexa, or, on their removal, the opening of the peritoneum, which had better be done from above. Professor Mangiagelli (Milan) and Professor Chéron (Paris) also spoke, after which Dr. Segond replied.

About 2.30 the King came in and sat in his box in the Palais des Académies, where the meetings are being held, and remained listening to the discussion for about half an hour. At 3.30 the sitting was suspended to enable the members of the Congress to proceed to the Palace, where the King held a reception. The members were received in a spacious room, and were grouped according to their several countries. When the King came in each member was presented to him. He was very agreeable and gracious and spoke to each, after which tea, coffee, wine, cake &c. were served in another room. The staircase is of marble and is very elegant, and in one room are some excellent portraits of former occupants of the throne, reminding one of our own Royal Palaces. In the evening Dr. C. Jacobs, the general secretary, gave a dinner in the Hôtel Mengelle to some members of the Congress.

### *Friday's Proceedings.*

On Friday, the 16th inst., Dr. C. Jacobs removed two diseased ovaries and tubes by abdominal section in the usual way, with every aseptic care, but without any antiseptics.

Dr. Martin (Berlin) opened the discussion on Extra-uterine Pregnancy. He contended that most frequently the ovum was implanted in the tube, that ovarian attachment was less rare than was recently supposed, that the diagnosis of ectopic gestation was one of probability, and that the evolution of extra-uterine pregnancy rarely ends in retrograde metamorphosis without any intervening accident. Cases of development to term are so rare that to respect the interests of the child is to neglect those of the mother; consequently operative interference undertaken as soon as possible was advocated. Mr. Alban Doran drew attention to the fact that in so-called ovarian pregnancy what happened was that the ovary was flattened out over the sac. Professor Dimitri de Ott (St. Petersburg) urged operation in all cases.

M. Damion (Paris) read a paper on the Mechanism of Hæmorrhage in Fibrous Tumours of the Uterus and the Action of Electricity. He considered that electricity was of the greatest use for the arrest of the hæmorrhage, and that such arrest was not due to any caustic action, but to the

electro-dynamic action. Dr. Apostoli (Paris) gave a new contribution to the electric treatment, both faradaic and galvanic, in diagnosis in gynecology, and read a Note on a New Application of the Sinusoidal Alternative Current.

Dr. Murdoch Cameron (Glasgow) described his method of performing the Cesarean section. He demonstrated his use of a flat pessary, pressed over the uterus so as to avoid hæmorrhage while making the incision into the uterus, and recommended the use of Hagedon's needle to pass the stitches through the uterus.

Dr. More Madden (Dublin) submitted a communication in which he reviewed at considerable length the various diseases of the endometrium in which direct treatment was called for, and the methods by which this might be accomplished in each case. He then exhibited a set of adjustable instruments for intra-uterine work which, in accordance with his suggestion, had been made for him by Messrs. Arnold of London. Dr. More Madden, having demonstrated the method of using these instruments, concluded by urging a wider and earlier resort to endo-uterine treatment in all morbid conditions of the endometrium, by which he believed the extension of inflammatory and other lesions from the uterus and its appendages might in many instances be obviated, and the consequent necessity for grave laparotomy operations might, he ventured to think, be largely diminished.

During the course of the meeting the chair was successively taken by, among others, Dr. Barnes, Dr. Macan, Dr. More Madden and Mr. Alban Doran.

#### *Saturday's Proceedings.*

On Saturday, the 17th inst., we again visited Dr. Jacobs to see Dr. Martin of Berlin perform hysterectomy for the removal of a large fibroid, which he did with the greatest skill. He tied all the vessels as he went along with chromicised catgut, and finally dissected down carefully with scissors till he got to the os uteri, so that he removed the whole uterus; he then passed a pair of forceps up through the vagina, caught all the ligatures and brought them out through the vagina. He then sewed the peritoneum over the aperture from the abdominal aspect and closed the wound. The operation lasted about fifty minutes.

At the meeting at ten o'clock Dr. Berry Hart opened a discussion on Placenta Prævia. He maintained that our knowledge of the anatomy of the lower uterine segment is still defective, and it is in that segment that the placenta is situated in placenta prævia. He showed by a cast of the uterus taken from a frozen section of a case at the eighth month the situation of the two segments, and from diagrams and a section the anatomy of the spongy layer where the separation takes place.

Dr. Robert Barnes addressed the meeting in French. He commenced by expressing the pleasure he felt in hearing the instructive demonstrations of the anatomy of the subject by Dr. Berry Hart. He then showed that there were two methods of research: (1) the anatomical, pursued on the dead body; and (2) the clinical and physiological, pursued on the living. Dr. Hart's was an example of the anatomical method. His own, based, as he believed, upon unsurpassed experience, was the true clinical method. This it was that had led him to the true theory of placenta prævia and its treatment. At the same time he had not neglected opportunities of studying the subject on the cadaver. These anatomical observations confirmed the physiological and clinical experience. Dr. Barnes then drew attention to the fact that the division of the uterus into three zones—upper, equatorial and lower—had been described by him in THE LANCET in 1847 and again in 1857 in his Lettsomian Lectures, and that he then showed that the lower segment of the uterus was divided from the middle zone by a distinct "boundary line," thus marking out the lower segment of the uterus as the seat of placenta prævia. He contended that the whole treatment was not summed up in bipolar turning after the hæmorrhage ceased spontaneously and after artificial detachment. This had been shown long ago by Puzos, Wigand, R. Leo, Mercier, Cazeaux and others. Gellé (Provence), Verrier (Paris), Auvard (Paris), Gottschalk (Berlin) took part in the discussion.

In the museum there were exhibited a great number of useful and elegant instruments and preparations: Martin's instruments for hysterectomy, electrical machines, apparatus for the sterilisation of dressings and milk, and a machine for the relief of neuralgia by freezing. There was also a most convenient table for operations from Sweden, made with hollow tubes so that it could be warmed. Among the prepara-

tions I noticed a good one of exalgine in solution and also an elegant solution of sublimate, slightly coloured green, in a bottle marked off in divisions of five grammes for dilution; so that it could be easily measured. These were exhibited by the Société d'Hygiène Appliquée.

## CYCLING AND VITALITY.

### III.—ADVANTAGES.

IN previous articles we have exposed without any reserve certain of the evils of cycling. In that labour we have extenuated nothing nor set down aught in malice. Everything has been intended for the good of the cycling world, not a syllable for or towards its disparagement. We are willing, indeed, to admit that even in the extreme tricks with fortune which enthusiastic cyclists play there is a certain measure of good, and when they reveal to us, as they have so recently done in Mr. Shorland's ride of 367 miles in twenty-four hours, that man is, indeed, physically the strongest and most enduring as well as the most intellectual animal in creation, we are not so blind as not to admit the force of a lesson as interesting on its physiological as on its social and athletic side. It is a new truth of human possibilities, showing what in emergency a man can do and what the body can be trained to perform. Our advice to competitors like Mr. Shorland would be simply to be content with success, and not to continue to repeat great efforts until mischief is done to such fine and exceptional organisations as he and others like him possess.

Our task this week leads us to another and different subject. We are intent now on pointing out that cycling has many and signal advantages extending to the nation as a whole when, as an exercise, it is properly carried out.

The first advantage of it is that it relieves great and crowded communities of much bad air. It takes men, although in a small proportion, out of the close room or office into the open, leaves them free for ventilation and ventilates the cyclists themselves. Everyone who thinks on this matter will, even though he may have some prejudices upon it, concede so much. In such a city as London distance from the country had, so to speak, crippled healthy exercise. How could the busy youth, engaged from nine or ten in the morning until four or five in the afternoon, reach before the day was over even the borders of such places as Hampstead Heath, Barnes Common or Epping Forest? He would be wearied before he received the first breath of country air. He might go by rail; but there was the expense, the closeness and bustle of the station, the worry of a return journey, and the difficulties of so measuring out time as to catch the out-going and the in-coming trains. The result was that he was driven to remain in town month after month and year after year without change. He was by this necessity deteriorated. He might go to the billiard-table or to the bowling-alley; but his physical wants were not supplied. Man is an animal of out-door activity, and as such he demands scope for action like the strongest animals, and here he was cooped in like a bird in a gigantic cage. To such a prisoner the cycle has practically given wings. He learns to travel four times as quickly as he can walk. He learns the shortest roads into the country, and when he reaches his destination he can, without altering his mode of progress, enjoy the change he has passed into with the keenest sense of emancipation from an unnatural confinement. In addition, the exercise itself has for him its pleasant varieties; it brings into play muscles which, being long idle, add only weight to the body and become the storehouses of dead products—rusts which the eliminating organs have to dispose of by one or two channels alone which after a time are overtaxed and deranged in function. The exercise of cycling came in then opportunely for the physical wants and desires of a large and oppressed community—a community which could not ride on horseback and could not walk at such an advantage as would do good service; so far cycling rendered a service that was of really priceless value.

Something more has to be said in favour of the exercise. By it the mind is benefited as well as the body. The mind not less than the body pines under the penalty of home imprisonment. It must have freedom if it is to develop and

become sound and good. Let it rest day after day all through life, feeding on the same fare; let its eyes rest upon the same pictures, its ears receive the same grinding sounds, its nostrils absorb the same persistent odours, and how can it become anything more than a cribbed, wearied, discontented and dwarfed mind. The mind of the youth buried in the confined community was of this kind. It knew no expansion, felt no elasticity; became timorous, obstinate, feeble—what was called by the country folk the mind of Cockaigne, the cockney mind—afraid of the sight of every domestic animal, from a cow to a lapdog; frightened at sounds out of the range of Bow bells, and feeling the country to be a wilderness in which it was unpleasant and possibly dangerous to wander alone.

Cycling has changed these conditions as if by a magic spell. There are hundreds of Londoners now who know the English country better than the country people themselves, who have their road books and maps and tables of distances and lists of resting places in their pockets, who are so much master of their literature on these points that they can go everywhere, and who understand every turn they may have to make better than the yokel whose path they cross or the hotel-keeper whose house they visit. We heard one eminent military authority say quite recently that if he wished to place military scouts all over the kingdom for strategic purposes, or for the laying of electric lines, or for the conveyance of despatches from one distant place to another, he could find an efficient volunteer army of the sort in London alone within twenty-four hours in the corps of cyclists with which it is now provided. All this has been accomplished within—what shall we say!—a period of some sixteen years. Our memory carries us back to that time when Charles Spenser, in a little work called "The Modern Bicycle," introduced a charming account of a cycle journey from London to John o' Groats performed in fifteen days. We thought that a wonderful feat, and so it was, a feat as remarkably done as it was ably told. It opened the way to what is now commonplace in feats of skill and endurance; but it did more—it opened the way to that general scouring of the country by poor town dwellers, to which we have referred with so much gratification. To everything that favours the interests of health and usefulness THE LANCET has always held out a helping hand. It does so still. It has been admitted, not by us alone but by opponents of the cycling fraternity, that a complete revolution for good of mind as well as of body has been brought about by the cycle. In the work of the physician the exercise of cycling has become a prescription, and in many cases—those of melancholic dyspepsia especially—a prescription of great value. Our wish is that every good result from cycling, physical or mental, may be obtained by the exercise. It is only when we see it perverted and strained, when we see it becoming physically a cause of organic evil, that we venture to tender our admonitions. Morally everything seems good about cycling; at all events it has led to no special vice or crime. To its credit be it said that if it has excited competitive efforts, it has not done so in any spirit of gambling. It has encouraged and taught temperate habits and actually proved by hard contested trials their value. In short, whatever great evils it has called forth have been physical evils, affecting that vital mechanism which it is the duty of the medical profession to study and comment upon. Hence surely even the most enthusiastic cyclist will allow that we need no excuse for pointing out and strongly deprecating evils which our knowledge and experience have shown us to undoubtedly exist.

## TUBERCULOSIS IN THE CANINE SPECIES.

THE world-wide scourge of tuberculosis is daily attracting more attention and receiving closer investigation from the pathologist and sanitarian in regard to both man and animals. It is now a well-ascertained fact that a large number of the domesticated species have a receptivity for and are affected with this infectious disorder, and comparative pathologists are now not only engaged in finding out what species may be exempt, but the relative proportion of those likely to be infected in each species, the frequency of the lesions in different organs or tissues, the modes of infection, and the channels by which the virulent agent can obtain admission to the living body. Of course the ultimate aim of all this research is the limitation or absolute suppression of this serious devastating plague of man and beast.

It is probable that there is a unity in nature in the

tuberculosis of the various species of animals liable to the disease, the differences in the morbid anatomy and experimental results being due to differences in the soil in which the germ develops or other influences to which it is exposed during development, and that avian, bovine, equine, canine, porcine, caprine, and other forms of tuberculosis, as well as the human disease, are all one and the same in their nature, are spread and maintained in the same way, and depend for their origin and development on the same agent. We are in doubt, however, as to the species in which the disease primarily originates or originated, whether in man, the ox or other animal; but the notion has been lately started that the human race is infected from the bovine species, and that it is only among people who largely consume the milk and flesh of cattle that tuberculosis most frequently and seriously prevails.

It has been stated that bovine tuberculosis is a disease of domestication—of overcrowding and bad ventilation; but though insanitary conditions may, and doubtless do, tend to the propagation and maintenance of the malady, it must not be overlooked that there are other influences in operation in its development and extension, or why should famous and valuable herds, which are kept in the most healthy state amid the most perfect sanitary surroundings that can be devised, be decimated by this disorder? And in Queensland, which possesses one of the finest climates in the world, there is heavy loss among cattle from tuberculosis, though these have spent the whole of their existence in the open air, in the scrub or other fastnesses of the Australian bush, and have never even been in a yard except when being branded as calves. Here the majority of cases of outbreaks have been clearly traced to pedigree stud-cattle which had been imported from England, and which were doubtless infected before being exported; so that heredity might be invoked as an influence largely instrumental in keeping up and extending tuberculosis.

However this may be, the fact that the malady affects dogs can be no longer denied, and the subject has been well discussed at a meeting of the Société Centrale de Médecine Vétérinaire of Paris on July 13th, when Professor Cadiot of the Alport Veterinary School brought it forward for the second time. He had already in November last communicated three observations relative to tuberculosis in the canine species, and in these cases the range of the disease was limited to the lungs and pleura. Since that time he had continued his inquiries, with the result that he had discovered eight more cases; in these he found the localisation of the lesions variable; in some of them the lesions were generalised. He gave a minute description of two of the cases; one of them in particular was interesting from the point of view of morbid anatomy, the other being valuable on account of the manner in which a diagnosis was arrived at. In the first case, the lesions were found to be chiefly seated in the thoracic and abdominal serous membranes, and they were of such a character that a superficial observer might easily have mistaken them for malignant neoplasms. In the second case the disease appeared in the form of pleurisy—a form which is relatively common in the dog; as in twelve cases of pleural inflammation which Professor Cadiot had met with in this species during one year, six were of a tuberculous nature. In this instance, as the animal only exhibited symptoms of intra-thoracic effusion, though tuberculosis was suspected, recourse was had to a test for the presence of the disease, two guinea-pigs being inoculated by having a certain quantity of the fluid withdrawn from the dog's chest injected into their abdominal cavity. One of them died some days afterwards, and the other was killed before the dog succumbed; in both of them generalised tuberculosis was well established. In this way a correct diagnosis was arrived at in a very obscure case during the life of the affected animal.

An analysis of the cases of canine tuberculosis observed in France and elsewhere shows that the disease presents itself in all the forms observed in the other domesticated animals. The relative frequency of the tubercular localisations in the different organs is shown in the following table, which was compiled from 49 observations, 28 of these being made by Jessen, of the Copenhagen Veterinary School, and 14 by Professor Cadiot himself:—

Tuberculosis of the lungs ...	...	...	31 cases.
" " kidneys ...	...	...	17 "
" " spleen ...	...	...	6 "
" " prostate ...	...	...	4 "
" " bladder and urethra ...	...	...	1 "
" " epididymis ...	...	...	1 "
" " ovary ...	...	...	1 "

In nearly a moiety of these cases the liver, peritoneum and pleura were invaded by tubercle, and in nearly all there were multiple lesions of the lymphatic glands. Intestinal ulceration was rarely observed, even in the cases of mesenteric and peritoneal tuberculosis; from which it may be inferred that the bacilli, when they penetrate by the intestine, do not usually leave any trace of their passage through the mucous membrane. In the case of a dog, the body of which was examined by Müller, and which had been affected with pulmonary tuberculosis, there was a large cutaneous, tuberculous ulcer at the upper part of the neck; this sore had indurated margins, was covered with fine granulations, and a greyish, very fluid pus escaped from it. The adjacent lymphatic glands were indurated. These observations clearly establish the fact that in the canine as in the human species the pulmonary lesions predominate, so far as frequency is concerned, and that they are often primary—a fact in perfect accordance with the results derived from experimentation.

In the dog the ingestion of tuberculous matter only rarely yields positive results, while the inhalation of virulent dust is nearly always followed by pulmonary tuberculosis. With this animal, as with man, it would seem that infection through the air passages is the rule and inoculation by the digestive mucous membrane the exception. In the case of pet dogs, which are so frequently the inseparable companions of phthisical people, we can readily understand how infection by the lungs may easily occur; but this mode of infection could be effected in other circumstances, for dogs which frequent certain places—such as public-houses, cafés &c., where the sputa of phthisical persons are likely to fall on the floor and become dried—might become infected from inhaling dust that the sweeping of the ground raises in the lower strata of the atmosphere whence the dog derives the air it breathes.

## THE LONDON POST-GRADUATE COURSE.

THIS course has for its object the extension of post-graduate teaching in London and the utilisation of the clinical material not required by the medical schools. The year is divided into three terms, each of eight weeks' duration. The spring term commences about the middle of January and ends in March. The summer term includes May and June, and the winter term commences about the middle of October and ends in December. The teaching is essentially practical in character and the demonstrations and lectures are fully illustrated by cases.

Practitioners can enter for any single course or for a half term or for a whole term at a composition fee. The single courses consist of either eight or sixteen lectures, and the fees are £1 1s. and £2 2s. respectively. There will be twelve separate courses in the next winter term, and the composition fee is £15 15s. Arrangements have been made with the associated hospitals, so that members can enter for practice at any hospital at the rate of £1 1s. a month, and ample time is allowed for this part of the work. The demonstrations and lectures of the winter term, which will commence on Monday, Oct. 10th, and end on Saturday, Dec. 3rd, will be given by the following members of the staffs of the associated hospitals and institutions—viz.:

*Hospital for Consumption and Diseases of the Chest, Brompton.*—By Dr. Pollock, Dr. Green, Dr. Mitchell Bruce, Dr. Percy Kidd, Dr. Biss and Dr. Sidney Martin. Wednesdays and Fridays at 4 P.M.

*National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury.*—By Dr. Buzzard, Dr. Gowers, F.R.S., Dr. Ormerod, Dr. Beevor, Dr. Tooth, Mr. Victor Horsley, F.R.S., Mr. Brudenell Carter and Dr. Taylor. Thursdays at 2 P.M.

*Hospital for Sick Children, Great Ormond-street, Bloomsbury.*—By Dr. Sturges, Dr. Barlow, Dr. D. B. Lees, Dr. Lubbock, Mr. J. H. Morgan, Mr. Arbuthnot Lane, Dr. Colman and Mr. Wagstaffe. Thursdays at 4 P.M.

*Royal London Ophthalmic Hospital, Moorfields.*—By Mr. Marcus Gunn, Mr. W. Lang, Mr. Quarry Silcock, Mr. Lawford and Mr. J. S. Morton. Mondays at 1 P.M. and Wednesdays at 8 P.M.

*Hospital for Diseases of the Skin, Blackfriars.*—By Mr. Jonathan Hutchinson, F.R.S., and Dr. Payne. Tuesdays at 4 P.M.

*Bethlem Royal Hospital for Lunatics.*—By Dr. Percy Smith, Dr. Theo. Hyslop and Dr. Corner. Tuesdays at 2 P.M. and Saturdays at 11 A.M.

*London Throat Hospital, Great Portland-street, W.*—By Dr. Woakes, Mr. Stoker, Mr. W. R. H. Stewart, Dr. Law and Mr. Wilkin. Thursdays at 8 P.M.

*Bacteriological Laboratory, King's College.*—By Professor Crookshank. Fridays from 11 A.M. to 1 P.M.

*Pathological Lectures at 101, Great Russell-street, Bloomsbury.*—By Dr. Galloway. Mondays at 8 P.M.

*The Parkes Museum, 74A, Margaret-street, Regent-street, W.*—By Dr. Louis Parkes. Mondays at 4 P.M.

*Midwifery and Diseases of Women, at 101, Great Russell-street, Bloomsbury.*—By Dr. Dakin, Dr. Herman, Dr. Braxton Hicks, F.R.S., Dr. Potter and Dr. Amand Routh. Tuesdays at 8 P.M.

*Central London Sick Asylum, Cleveland-street, Mortimer-street, W.*—By Sir Alfred Garrod, F.R.S., Dr. Ord, Dr. Wilks, F.R.S., Mr. Bryant, Mr. Timothy Holmes, Mr. Jonathan Hutchinson, F.R.S., and Mr. Hopkins. Thursdays at 5.30 P.M.

A prospectus may be obtained on application to J. Fletcher Little, M.B., Secretary, 60, Welbeck-street, London, W.

## THE METROPOLITAN ASYLUMS BOARD.

### STATEMENT BY THE CHAIRMAN.

AT a meeting of the Managers of the Metropolitan Asylums Board, held on the 17th inst., the Chairman, Sir Edwin H. Galsworthy, referred to the complaints made that, notwithstanding the Board possessed all information as to the prevalence of disease in every part of the metropolis, and that the financial resources of London were at their call, they had failed to keep pace with the demands made upon them for hospital accommodation. He said that to completely vindicate the Managers it would be necessary briefly to review the events of the past few months. As early as May last the Ambulance Committee reported that the number of patients under treatment exceeded by 473 the greatest number on the corresponding day in any previous year, and estimated that the Managers would have to provide at least 1000 further beds, a large portion of which, to be of any use, would have to be ready before the middle of August. In less than a fortnight preparations were being made for no fewer than 994 patients, but the committee pointed out that at the then rate of increase this extra accommodation would be occupied in less than eleven weeks. All necessary steps were taken for the temporary accommodation of patients, and instructions were given to their architects, Messrs. Harstons, to look out for suitable land for hospital purposes, temporary or permanent. The consent of the Local Government Board to use the Gore Farm Hospital for convalescent patients was also obtained. The Managers were now nearing the end of their resources. They did not wish to erect temporary buildings at the Northern Hospital or at the Gore Farm Hospital unless absolutely compelled to do so. On being applied to, the Local Government Board expressed their regret at not being able to allow the Managers of the Asylums Board to utilise any of the London workhouses for the reception of fever patients. The statement of the chairman contains reference to the tardy action of the Local Government Board regarding the erection of a new Fever Hospital at Tottenham. Sanction was eventually obtained and he hoped the hospital would be ready for patients by the end of the month. Taking into consideration these circumstances, he thought the Managers could not be blamed for the deplorable fact of the sick poor lying in their crowded homes without proper accommodation or care and without the means of alleviating their sufferings which could be obtained in a hospital. The statement concludes: "The Metropolitan Asylums Board accepts no responsibility for a state of things which they condemn and deplore, but which they did all that it was in their power to do to avoid. The responsibility is with the Local Government Board—that body which it is expected will use its extensive powers to protect the public health and to alleviate the sufferings of the poor; the body on which the Managers, with their limited and crippled powers, ought to be able to rely for all due assistance in the performance of their arduous and responsible duties. The Local Government Board for three weeks—three precious weeks—left the

Managers' earnest application of June 22nd unattended to, or at least unanswered, and then caused still further delay by holding what, under the pressing necessities of the case, would seem to have been a formal and unnecessary inquiry before they gave their consent to the purchase of the Tottenham land, and it is in consequence of these delays that the hospital is not ready and that the Managers have been and are from day to day compelled to suspend the reception of many fever patients."

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6442 births and 3643 deaths were registered during the week ending Sept. 17th. The annual rate of mortality in these towns, which had been 19·8 and 18·9 per 1000 in the preceding two weeks, further declined last week to 18·6. In London the rate was 16·9 per 1000, while it averaged 19·9 in the thirty-two provincial towns. The lowest rates in these towns were 9·7 in Huddersfield, 12·2 in Plymouth, 13·6 in Halifax and 13·8 in Bristol, to 23·4 in Hull, 23·5 in Gateshead, 25·0 in Derby, 27·7 in Preston and 30·1 in Salford. The 3643 deaths included 747 which were referred to the principal zymotic diseases, against 984 and 899 in the preceding two weeks; of these, 463 resulted from diarrhoea, 65 from scarlet fever, 59 from whooping-cough, 54 from measles, 54 from diphtheria, 50 from "fever" (principally enteric) and 2 from small-pox. The lowest death-rates from these diseases were recorded last week in Brighton, Wolverhampton, Huddersfield, Bristol and Halifax; and the highest rates in Leeds, Oldham, Hull, Salford and Preston. The greatest mortality from measles occurred in West Ham, Salford and Oldham; from scarlet fever in Salford, Cardiff, Oldham, Gateshead and Preston; from whooping-cough in Salford, Swansea and Birkenhead; from "fever" in Sunderland; and from diarrhoea in Manchester, Bolton, Gateshead, Derby, Sheffield, Leeds, Hull and Preston. The 54 deaths from diphtheria included 36 in London, 4 in West Ham, 3 in Liverpool and 3 in Cardiff. A fatal case of small-pox was registered in Leicester and one in Halifax, but not one in any other of the thirty-three large towns; four cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 3 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3412, against numbers increasing from 3088 to 3339 on the preceding four Saturdays; 349 new cases were admitted during the week, against 461 and 414 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 114 and 125 in the preceding two weeks, further rose to 142 last week, but were 35 below the corrected average. The causes of 70, or 1·9 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Portsmouth, Cardiff, Sunderland, Newcastle-upon-Tyne and in six other smaller towns; the largest proportions of uncertified deaths were registered in Wolverhampton, Norwich, Liverpool and Huddersfield.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 15·7 and 16·6 per 1000 in the preceding two weeks, further rose to 17·0 during the week ending Sept. 17th, but was 1·6 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 8·6 in Perth and 11·2 in Leith to 18·8 in Glasgow and 19·0 in Greenock. The 474 deaths in these towns included 26 which were referred to diarrhoea, 13 to scarlet fever, 12 to measles, 7 to diphtheria, 7 to "fever," 5 to whooping-cough and not one to small-pox. In all, 70 deaths resulted from these principal zymotic diseases, against 67 and 61 in the preceding two weeks. These 70 deaths were equal to an annual rate of 2·5 per 1000, which was 1·3 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhoea, which had declined from 34 to 24 in the preceding two weeks, rose again to 26 last

week, of which 16 occurred in Glasgow and 4 in Dundee. The deaths referred to scarlet fever, which had been 14 and 10 in the previous two weeks, rose again to 13 last week, and included 7 in Glasgow, 2 in Edinburgh and 2 in Aberdeen. The 12 fatal cases of measles exceeded by 6 the number in the preceding week and included 7 in Edinburgh and 4 in Glasgow. The deaths from diphtheria, which had been 4 and 6 in the preceding two weeks, further rose to 7 last week, of which 3 occurred in Glasgow, 2 in Dundee and 2 in Perth. The 7 fatal cases of "fever" also showed a further increase upon recent weekly numbers and included 3 in Glasgow and 2 in Paisley. Four of the 5 deaths from whooping-cough were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 57 and 59 in the preceding two weeks, further rose to 71 last week, and exceeded by 18 the number in the corresponding week of last year. The causes of 44, or more than 9 per cent., of the deaths in these towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the preceding four weeks from 19·5 to 28·3 per 1000, declined again to 23·3 during the week ending Sept. 17th. During the first eleven weeks of the current quarter the death-rate in the city averaged 23·5 per 1000 against 17·4 in London and 16·3 in Edinburgh. The 156 deaths in Dublin during the week under notice showed a decline of 34 from the number in the preceding week, and included 18 which were referred to diarrhoea, 4 to "fever," 1 to measles, 1 to whooping-cough, and not one either to small-pox, scarlet fever or diphtheria. In all, 24 deaths resulted from these principal zymotic diseases, equal to an annual rate of 3·6 per 1000, the zymotic death-rate during the same period being 2·8 in London and 2·2 in Edinburgh. The fatal cases of diarrhoea, which had increased from 9 to 28 in the preceding three weeks, declined again to 18 last week. The deaths referred to different forms of "fever," which had been 2 and 4 in the preceding two weeks, were again 4 last week. The 156 deaths registered in Dublin last week included 39 of infants under one year of age and 22 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from those recorded in recent weeks. Only one inquest case and no deaths from violence were registered during the week; and 48, or nearly a third, of the deaths occurred in public institutions. The causes of 19, or more than 12 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

### MOVEMENTS OF THE MEDICAL STAFF.

Surgeon-Colonel Markey has embarked for Madras on the termination of his leave of absence. Surgeon-Colonel Preston has resumed duty as Principal Medical Officer at Belfast. Surgeon-Captains Bean and Addison have embarked for Bombay to perform a tour of duty in India. Surgeon-Captains Westcott and James have embarked for Hong-Kong, and Surgeon-Captain Allport for Ceylon. Surgeon-Major Franklin has joined for duty at Eastbourne, and Surgeon-Captain Cocks at Brighton. Surgeon-Major Stevenson has been granted leave from India. Surgeon-Captain Woods has arrived in Alderney for duty. Surgeon-Lieutenant Hughes has rejoined at Preston, and Surgeon-Lieutenant Holt at Gosport. Surgeon-Captain Magrath has rejoined at Portsmouth from trooping duty and Surgeon-Captain Elderton from Portland. Surgeon-Captain Mumby is on leave prior to embarking for India, and Surgeon-Captain Gubbin is on leave awaiting embarkation for Bermuda. Surgeon-Captain Leishman has been granted sick leave from Bengal. The undermentioned officers of the Army Medical Staff who are at present serving on the Bombay Establishment have, on completion of their six years' tour of Indian service, been selected to return to England during the trooping season of 1892-93:—Surgeon-Lieutenant-Colonel W. F. Burnett; Surgeon-Captains R. J. A. Durant, J. W. B. Buchanan, S. J. W. Hayman and R. J. D. Hall.

### INDIAN MEDICAL SERVICE.

H. E. the Governor in Council is pleased to appoint Surgeon-Captain H. W. Stevenson to act as Medical Officer on his

Excellency's staff during the absence of Surgeon-Major H. Martin, M.B., on privilege leave. Surgeon-Lieutenant W. E. A. Armstrong, I.M.S., to do duty in the Southern district. Surgeon-Lieutenant-Colonel D. D. Cunningham, Officiating President of the Committee of Management of the Zoological Garden, Calcutta, is confirmed in that appointment, vice Sir John Edgar, K.C.I.E., C.S.I., resigned. Surgeon-Major H. K. McKay, Officiating Civil Surgeon, Nagpur, is appointed to be Honorary Surgeon, Nagpur Volunteer Rifle Corps, vice Surgeon-Major G. F. A. Harris, I.M.S., on furlough, and who has been placed on the rolls as a supernumerary. The Queen has approved of the retirement from the Service of Surgeon-Lieutenant-Colonel John Edwd. Charnock Ferris, Bengal Medical Establishment (dated Aug. 1st, 1892).

#### NAVAL MEDICAL SERVICE.

The following appointments have been made:—Staff Surgeon Alfred Thomas Corrie has been appointed to the rank of Fleet Surgeon in Her Majesty's Fleet (dated Sept. 8th, 1892). Surgeons: Herbert P. Shuttleworth to the *Pembroke*, additional, to be lent to the *Briton* for the training season, from Sept. 26th; Richard A. Fitch, to the Royal Marine Artillery, Portsmouth; Charles J. Fyfe to the *Pembroke*, additional, for disposal; Edward M. Dobinson to the *Wildfire*, additional, for service at Walmer Depot; Octavius S. Fisher to the *Defiance*, additional, for disposal; and William M. Craig to the Plymouth Division Royal Marines (all dated Sept. 15th, 1892); A. M. Page to Plymouth Hospital, and Daniel J. P. M'Nabb to the *President*, additional, for three months' study (both dated Sept. 22nd, 1892). M. W. Roe to be Surgeon and Agent at Helford Passage (dated Sept. 20th, 1892).

#### VOLUNTEER CORPS.

*Artillery*: 1st Lancashire: Surgeon-Lieutenant T. M. Dawson to be Surgeon-Captain (dated Sept. 17th, 1892).—2nd Glamorganshire: Surgeon-Lieutenant J. H. Rees, M.D., to be Surgeon-Captain (dated Sept. 17th, 1892).—*Royal Engineers*: 1st Lancashire: John Morgan Whiteford, Gent., to be Surgeon-Lieutenant (dated Sept. 17th, 1892).—*Rifle*: 2nd Volunteer Battalion, the Sherwood Foresters (Derbyshire Regiment): Surgeon-Captain J. Knox to be Surgeon-Major (dated Sept. 17th, 1892).—5th (Ardwick) Volunteer Battalion, the Manchester Regiment: Brigade-Surgeon-Lieutenant-Colonel J. Armstrong resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated Sept. 17th, 1892).

#### THE SICKNESS AND MORTALITY AMONG YOUNG SOLDIERS IN INDIA.

Our Indian contemporary, the *Pioneer* of the 31st ult., gives some information on this point, to which we may briefly refer. It had recently instituted a comparison between the Gordon Highlanders, a seasoned regiment, and the Argyll and Sutherland Highlanders, who arrived in India last Christmas. Both regiments are in the Simla Hills. Since the latter regiment arrived at Dugshai on March 21st last there have been seventy-four cases of enteric fever, nine proving fatal. In a detachment of 115 men of the Derbyshire regiment, living a little lower down the hillside than the Highlanders, there have been only two cases of enteric fever. The soldiers of this detachment are alleged to have been acclimatised by residence in India. The West Yorkshire regiment, which went out to India in 1878, was last year stationed at Dugshai and had only ten or eleven cases of typhoid fever. Although it has been abundantly shown that new arrivals in the country are very liable to be attacked with this disease it does not follow that the station, Dugshai, is not responsible, from some cause or other, for the outbreak this year; and it would, in our opinion, be well worth undertaking a thorough investigation into everything connected with the conservancy, water and milk supplies, and the sanitary condition of that station.

#### DESIGNATION OF MEDICAL OFFICERS.

The designation of the Principal Medical Officers of Her Majesty's Forces in Madras and Bombay is to be altered to Principal Medical Officer of Her Majesty's Forces in the Madras Army and Bombay Army respectively, so as to distinguish them readily from District Principal Medical Officers located in the towns of Madras and Bombay.

Surgeon-General Longmore's treatise upon Ambulance Transport has, we understand, been undergoing revision, and will shortly appear in its revised form with all the modifications and improvements effected up to date.

## Correspondence.

"Audi alteram partem."

### "THE LANCET COMMISSION ON SANITATION IN RELATION TO THE LAW AND PRACTICE OF HOUSE-LETTING."

To the Editors of THE LANCET.

SIRS,—I have lately read with great interest the articles and correspondence which have followed the publication in your issue of Aug. 20th of the very admirable report of THE LANCET Special Commission on the above subject. To the supreme importance of this matter the Teignmouth Local Board is keenly alive, and a system of inspection, certification and registration, conducted on lines very similar to those in force at Eastbourne and Folkestone, has for some time been satisfactorily working in this district. A thorough and exhaustive inspection is performed by the sanitary inspector in person on receipt of written application from the householder. This is done gratuitously, and the inspector advises as to the works necessary to secure a certificate, which is only granted when the requirements enumerated in Dr. Sherwood's article are complied with. The incorporation of these requirements in the printed certificate is an improvement for which I owe a debt of gratitude to Dr. Sherwood, and which I shall endeavour to persuade my board to adopt without delay. The register of certified houses is kept in the clerk's office and is open to inspection, a conspicuous painted notice-board to that effect being affixed to the wall of the market-place. Further, every medical practitioner and every house agent in the district are provided with a list of certified houses, corrected quarterly, in the clerk's office. The advantages of this plan are too obvious to call for comment. This system was inaugurated in Teignmouth in 1889, and the earliest certificate bears date Nov. 28th of that year (so that we may justly claim to have anticipated Eastbourne in this much-needed work of reform by a few months), and numbers of private householders, in addition to a large majority of the lodging-house keepers, have gladly availed themselves of the facilities thus offered for ascertaining with certainty the sanitary condition of their homes.

The following brief statement of facts will help to emphasise the urgent necessity of extending the above or some similar system to all towns. From October, 1889, to the end of 1891 the sanitary arrangements of 232 houses were carefully examined. Taking the results of the smoke test alone, in only eighteen of these 232 were the drains found smoke-tight; in other words, 92.25 per cent. of the houses were liable to contamination with sewer gas. As I am not aware of any very cogent reason for believing that the condition of house sanitation in my district is markedly inferior to what prevails in other parts of the country, I am inclined to suspect that 90 per cent. may fairly be supposed to represent the proportion of insanitary houses in the average watering-place. It would be interesting to know whether the experience of Eastbourne and Folkestone supports this idea, which, as I am well aware, is a generalisation on very insufficient data; it seems to me, however, not unlikely to be true, and if true, can anything be more appalling? Short of parliamentary action on the lines of Dr. Farquharson's Bill, the only remedy for such a condition of things is that all municipal bodies and individuals alike, should realise that a positive knowledge, a certainty, of the perfection of his house sanitation is a duty which each man owes not only to himself but also to his neighbour. Moreover—and this is likely to be a more generally convincing argument—attention to the aforesaid duty is, at any rate in watering-places and health resorts, a form of honesty which is most emphatically "the best policy."

I am, Sirs, yours faithfully,

F. CECIL H. PRIGGOTT, M.D., B.C. & B.A. Cantab.,  
Medical Officer of Health.

Teignmouth, South Devon, Sept. 10th, 1892.

P.S.—One expects, with reason, before many years are

past, to observe a diminution in the incidence and mortality of zymotic disease in towns where the registration system is widely extended and efficiently carried out.

### THE NOTIFICATION OF DISEASE.

To the Editors of THE LANCET.

SIRS,—There is a point concerning this subject that I should like to ventilate, as it is an important one to a large section of medical men. Some months ago a medical gentleman in the parish of St. George's, Hanover-square, asked me to see a case of diphtheria with him and I did so. The child was choking, and the only thing that could be of any avail was tracheotomy or intubation; and I left the house after giving that opinion, and I believe that a surgeon was applied to and that an operation of some kind was performed. Some few weeks afterwards I was much surprised to receive a curt official note from the office of the medical officer of health for the said parish, inquiring why I had not notified the case to him, as I was bound to do. I replied that I never did notify; that I always left that duty to the medical man in charge. The answer I received to this was that the Act requires everyone who is called in to a case of any infectious disease scheduled under the Act to notify, and I was pointed to the wording of the Act, which reads that "everyone attending or called in to visit shall" &c. I was further politely informed that as I had sinned in ignorance no action would be taken on this occasion. In other words, I must not be a bad boy again, or I should receive a whipping.

Now there is no doubt that the strict letter of the Act is in accord with the contention of the medical officer of health of St. George's, Hanover-square, but it is obvious to me that this strict interpretation of it was not intended by its framers; for see what it leads to. In the case I have given three of us saw the case and we all were in duty bound to notify. In another instance the gentleman who first saw the case notified it as scarlatina; I came next and thought it was enteric fever; a friend who saw the gentleman in my absence did not know what it was, and after a few days it turned out to be influenza. Take one other illustration. I saw in consultation a bad case of scarlatinal nephritis in the fourth or fifth week after the fever. The boy was peeling freely. He was infective enough certainly. According to the medical officer of St. George's, Hanover-square, I ought to have notified. If so, there would be no end to the work of the medical officers of health. Their energies would be eaten up in finding out who was who and what was what. But, Sirs, I would interpret the letter of the law thus: everyone "*attending or called in to visit*" is a legal periphrasis deliberately intended by the draughtsman to cover his man—*viz.*, the doctor first called in to see the patient—and very wisely so worded, in my opinion, for there are many cases where there is no *attendance*, the doctor is merely called in to say what a disease is, and he never sees the case again. The only instance in which I have myself notified was a case of this sort. There was no one in *attendance*, but I was covered by the Act, being "*called in to visit*," so I notified. I venture to urge, Sirs, most strongly, that this is the reasonable and right interpretation of the Act as regards the duty of those called in as consultants, and indeed I have reason to know that a large number of medical officers of health do so construe the meaning of the Act; but there is at any rate one, and he unfortunately no mean authority, who thinks otherwise. The matter requires ventilation.

I am, Sirs, yours faithfully,

Weymouth-street, Sept. 20th, 1892.

J. F. GOODHART.

### THE CHOLERA SCARE AT EYEMOUTH.

To the Editors of THE LANCET.

SIRS,—I beg to forward you the particulars upon which, so far as I am aware, the report of the cholera scare in Eyemouth has been founded. When recently it became known here that the schooner *Spray* was chartered to Eyemouth with a cargo of old empty herring barrels from the cholera-infected port of Hamburg the inhabitants became greatly alarmed. For weeks past, however, in accordance with the Infectious Diseases Act, everything has been done in the way of sanitation and general precautionary measures, and the local authority, acting on instructions from the Board of Supervision, had promptly devised means to have all ships from foreign ports boarded by the medical officer of health

as soon as they should be reported to him. On the 13th inst. the *Spray* was reported in the offing and immediately intense alarm took possession of a considerable portion of the inhabitants and the opinion generally prevailed that if she came into port the risk of disseminating the choleraic virus would be by no means inconsiderable. Being unable to secure a boat and board the *Spray* outside, she was allowed to come into the harbour, and so soon as a berthing was obtained I got aboard, accompanied by the Customs officials. There was, or had been, no sickness on board, and so she was accordingly passed. The tanks were empty and no bilge-water had been made, and beyond ordering her hold to be fumigated nothing more was done. Nevertheless, a brisk controversy has taken place in regard to the disposal of the cargo, many people asserting that a public danger would be occasioned to health through the landing of this possibly infectious material. A meeting of the local authority was held to consider the situation, and it was at first resolved to ask of the captain five hours' notice of the landing of the cargo. It seems, however, that no purchaser could be found, so strong was the feeling in the town; as the result of later deliberations between Captain Wilson and the local authority, however—in view of the intense public opposition, and as remuneration for any loss the master of the *Spray* might sustain—a number of townspeople subscribed and made a present in money to him, at the same time stating that the vessel should leave this port by the next tide. Owing to some of his crew having left, the schooner *Spray* only put out to sea this morning.—I am, Sirs, yours faithfully,

JAMES FORSYTH,

Medical Officer.

Eyemouth, Sept. 17th, 1892.

### "THE ETHICS OF OPIUM AND ALCOHOL."

To the Editors of THE LANCET.

SIRS,—With reference to Dr. Mouat's very interesting article on the "Ethics of Opium and Alcohol," I should like to point out that I have had very similar experiences of the pick-me-up action of opium and have also given what I believe to be a very complete explanation of the way in which it produces the effects in question. Shortly stated, my explanation amounts to this: that opium, by clearing the blood of uric acid, frees the circulation in the small vessels throughout the body, and the effect of this on the nerve centres and muscles, for instance, is to bring about a state of affairs in which all their functions are performed with the greatest ease and smoothness, doubtless because their metabolism is well and easily maintained. But if the opium is not continued there comes what I have called a rebound; the urate begins to find its way back into the blood in greater quantity than before, because the amount previously cleared out of the blood was stored up in the body and not eliminated. The arterioles are now contracted just in proportion to their previous dilatation, the pulse is slow, the tension high, the circulation through the brain and muscles is deficient and lethargy of mind and body results.

I have often used opium as a pick-me-up and it is most efficient, and I have pointed out that many well-known persons appear to have had similar experiences and that it is a great fallacy to suppose that men are seeking for oblivion when they take opium, cocaine and drugs of similar action; but I know also that it has a rebound, and that just as my mental and bodily powers are, say, 50 per cent. above normal during its primary action, so will they be 50 per cent. below normal during its secondary action (rebound). During the primary action I may have been able to perform feats of body or mind which were otherwise, as far as I was concerned, impossible. The Sikh infantry regiment mentioned by Dr. Mouat might by their magnificent march under opium have saved their own lives and those of many others. Were they wrong in resorting to it to enable them to do this? I have also pointed out that when a small dose of opium has been taken as a pick-me-up the rebound can be almost completely averted by taking one or two doses of salicylate, as this eliminates the urates stored up during the primary action of the opium, and, the subsequent excess of urate in the blood being thus prevented, there is no rebound. This action of a salicylate affords a further proof that the action of opium first as a pick-me-up and then as a depressant is entirely due to its effects on the alkalinity of the blood, which in turn determines the amount of urate it can hold in

solution, and so the relative contraction or dilatation of all the arterioles of the body.

I am, Sirs, yours faithfully,  
Brook-street, W., Sept. 10th, 1892. ALEXANDER HAIG.

*To the Editors of THE LANCET.*

SIRS,—I should be glad if Dr. Mouat would specify the sentence in which occurs "the insinuation that the corruption of the subordinate agents of the prisons caused the smuggling of opium in such quantities as to cause a prejudicial influence on death-rates." Dr. Pringle, I observe, suggested that the smuggling exerted an opposite influence. What is Dr. Mouat's explanation of the apparent discrepancy in his vouching "absolutely for the correctness of the returns themselves," and yet saying of one of them, "This record again I believe to be inexact"?

Dr. Mouat says "the diseases chiefly influenced by opium were dysentery and diarrhoea," and that one-fourth at least of the whole mortality was due to dysentery alone. Is this an approval of the suggestion that opium predisposes to dysentery?—I am, Sirs, yours faithfully,

J. BARCROFT ANDERSON, M.B., B.Ch. Dub. Univ., &c.  
Dublin, Sept. 20th, 1892.

### THE MIDWIVES' REGISTRATION BILL.

*To the Editors of THE LANCET.*

SIRS,—In THE LANCET of Sept. 17th you publish a letter from Dr. Alderson relative to "Midwives and Abnormal Cases." Will you allow me to point out some of the errors he has fallen into? He opposed the late Midwives Bill, he says, because it would have certificated hopelessly incapable people; but he has forgotten that there was a clause requiring proof of a fair amount of knowledge before registration. In the case he gives, supposing the hopelessly ignorant woman who assumed the name of midwife had had her name placed on the Midwives' Register, it would have changed the verdict into one of culpable negligence; and even if she had succeeded in persuading the jury that registration did not imply necessarily knowledge, she would still have had her name removed from the Register and have experienced that amount of punishment now noticeable by its entire absence. He thinks that "midwives should only be allowed to act under the eye and responsibility of a medical man," and that a poor patient should be attended by the club or parish doctor. This might be desirable. These women have the opportunity of so doing now, and will not have the one while they either cannot or will not have the other; at any rate, they do not have doctors to attend them, and indeed it would be quite impossible for doctors to do all the "cheap" work thus thrown on them and live on the results. I would ask him why a medical man should bear the misdeeds of an "obstetric nurse" on his shoulders merely because he was engaged by a patient in case of the requirement of his services. He would have to wait till sent for and then be responsible for not having come sooner. Who is to pay the expense of this arrangement, for which alternative Dr. Alderson has thrown his weight against the Bill? The patient can hardly pay the midwife, let alone paying retaining fees or fees for services rendered. The fact is that the poorer classes, in their very laudable endeavours to be independent, prefer, in their ignorance of the risks they run, to be attended by a person whose charges come within their means. It cannot be denied that an immense number of poor people are attended by incompetent or untrained women. I have in front of me letters just received from two medical men practising in a manufacturing town of 60,000 inhabitants, mostly poor, and these are nearly all attended (so they tell me) by untrained women because they cannot pay doctors' fees. Dr. Alderson has opposed a much-needed Bill for fear of a provision in it which could not have been left out and which would have been remedied by lapse of time in a few years.

I am, Sirs, yours faithfully,

F. ROWLAND HUMPHREYS.  
Fellows-road, N.W., Sept. 20th, 1892.

### THE SANITARY CONDITION OF WELLINGTON, NEW ZEALAND.

*To the Editors of THE LANCET.*

SIRS,—In THE LANCET of June 11th appears a critique upon the sanitary condition of Wellington, in which the writer states that "dirt, disease and death have given this

city an unenviable notoriety among the cities of the colony." This is painfully unjust, as my report most clearly proved. Previously to 1890 there was comparatively little typhoid fever. During that year there were 109 cases, 50 of which occurred in a small area of several blocks of buildings in the Te Clio end of the town. In 1891 there were 107 cases and 57 came from this same area; while during the first quarter of 1892 there were 62 cases and 56 came from exactly the same locality, leaving 6 only from the remaining part of the city. The area under notice covers a space of about 100 acres, while the populated area of the city is 1500 acres. It is obvious therefore that only one little spot, one-fifteenth of the town area, deserves the severe criticism of your correspondent; the rest of our town enjoys comparative immunity from all forms of zymotic disease. My report clearly shows this; and of all the things said of Wellington, sanitation was the most just and at the same time the most complimentary, for it freed fourteen-fifteenths of the city from the cloud that hung over it. New arrivals who have read the scathing criticism of this our empire city must be very pleasantly surprised at the general cleanliness of our streets, the elevation of our houses on the hill-side and the ample space around each, admitting light and air and sunshine in rich abundance and surpassing purity. The affliction of a prince, not the zymotic mortality, has given Wellington a reputation almost wholly undeserved. Defects in house and town drainage may occur anywhere and at any time. Local house-drain defects caused the illness of Lord Cranley and local town defects caused the epidemic of Te Clio. The former of these have been successfully remedied and the latter are being remedied by the Council, who, despite the aspersions cast upon them, have overcome many difficulties and accomplished much in sanitary reform.

I am, Sirs, yours faithfully,  
Wellington, N.Z., Aug. 11th, 1892. W. A. CHAPPLE.

### THE PATHOLOGY OF DROPSY.

*To the Editors of THE LANCET.*

SIRS,—At the present time, when the pathology of dropsy is being so much discussed, the subjoined case of dropsy without albuminuria following scarlet fever may be worth recording:—On Sept. 5th I was called to see L. M—, a little boy aged six, who was suffering from well-marked scarlet fever; throat, tongue and rash were all typical; the temperature was 102°. The case ran an ordinary course, and by Sept. 9th the temperature was normal and the rash had almost disappeared. I had tested the urine daily as a matter of routine, but had found nothing abnormal. On Sept. 10th when I called I found considerable swelling of the whole face, especially marked on the upper lip, and the complexion pale and rather waxy-looking; there was also swelling of the left leg and slightly of the scrotum; the temperature had run up to 100.4°. I expected to find the urine highly albuminous, but was surprised to see, on testing by boiling, that there was no precipitate, nor was there any reaction with either nitric or picric acid. The amount of urine passed was unfortunately not measured, but the patient's mother stated that he had not passed nearly as much as usual. I ordered a mixture containing digitalis, and on the next day (Sept. 11th) the swelling had nearly disappeared, while to-day (Sept. 12th) there is none discoverable and the waxy complexion has given way to a more healthy colour. I have examined the urine at different times, before and after meals, but have quite failed to find any albumen. I offer no explanation of these facts, but content myself with recording them.

I am, Sirs, yours faithfully,  
Southend, Sept. 13th, 1892. W. A. MURRAY, B.A., M.B.

### THE RADICAL CURE OF INGUINAL HERNIA.

*To the Editors of THE LANCET.*

SIRS,—If it were admitted that a particular method of obtaining a definite result was the best, then I take it many methods of attempting to do so would not be recommended; but for the radical cure of hernia several operations are advocated, and no one has been adopted as the best. In drawing attention to another, the peculiarity of which is the introduction of a new principle, I hope I have not done injustice to any other procedure. I congratulate Mr. Burghard upon the success of his eight cases of radical cure by Bassini's operation, but I still think that by Halsted's recurrence is less

likely to occur than by any other plan with which I am acquainted. Naturally I cannot expect Mr. Burghard to agree with me, as he is enthusiastically in favour of another operation, but I should be very much gratified if I could persuade him to give Halsted's a trial.

I am, Sirs, very truly yours,  
Newcastle-on-Tyne, Sept. 19th, 1892. FREDERICK PAGE.

### "PSYCHO-THERAPEUTICS."

To the Editors of THE LANCET.

SIRS,—In Dr. Robertson's article on "Psycho-Therapeutics" in THE LANCET of last week he corroborates my views on the subject, as stated in the summing up of my article which he criticises. For speaking of certain occult power which some few persons possess over the minds of others through suggestion, he says "the possession of this power by one or two members is of very little value to the profession as a whole." Just so. He might have added—and there are few upon whom this power has any influence. I stop at "relics," "magnetic healing" and tricks with "cold water," "bread pills" &c., believing that in the end they can only do harm. Nor have I any faith in hypnotism, which is merely another form of the miserable farce, mesmerism, which in my youth wrecked poor Dr. Elliottson's reputation. But in the observations in Dr. Robertson's article respecting certain "physicians of celebrity" and family doctors and their success in the treatment of disease I think he corroborates my views; for by their tact and personality that "faith and hope" of which I have spoken are created in their patients which will enable them "to make at least a brave stand against their foes." I still believe, therefore, and regret that "he who expects more than this from the influence of the mind on the body in treating disease will be disappointed."

I am, Sirs, yours obediently,  
Bishop's Tselgton, South Devon, Sept. 20th, 1892. WM. DALE.

### "OUR DUTY TO OUR PATIENTS."

To the Editors of THE LANCET.

SIRS,—In the last issue of THE LANCET I notice a letter on this subject signed "Spes," which calls attention to the desirability of having some simple common-sense rules printed for circulation on various health subjects which would educate the working classes on matters pertaining to the health and comfort of their children and themselves. It is not so generally known as it ought to be that there is an institution whose special work is in this direction—viz., the Ladies' Sanitary Association, of 22, Berners-street, W. They publish a large variety of leaflets, cards, tracts, &c. on all health subjects, including those which "Spes" mentions as most needed: "The Care of Mothers recently Confined," "How to Wash and Dress the Baby," "How to Feed the Baby." A list of these useful and inexpensive publications can be obtained by application to the Secretary, Miss Rose Adams.

I am, Sirs, yours truly,  
J. SINCLAIR HOLDEN, M.D., M.O.H.  
Sudbury, Suffolk, Sept. 20th, 1892.

### ADULTERATION AND THE INSPECTION OF MEAT: RECENT BELGIAN LEGISLATION.

(FROM OUR SPECIAL CORRESPONDENT.)

THE Belgian Government has been working quietly but very earnestly during the last few years, with the result that the laws framed to ensure the wholesomeness of alimentary substances have been considerably improved and strengthened. It is a difficult and tedious matter to analyse the legislation of a country, even if such analysis is limited to one single subject. Considerations of space make it impossible to give a complete synopsis of the Belgian law on markets, slaughter-houses, and on the adulteration of food. But in the laws recently enacted there are such good points that these improvements at least merit full notice. For ample information the reader must consult the text of the laws. Thus the entire law on the adulteration of alimentary substances, published in the

*Moniteur Belge* of Aug. 18th and 19th, 1890, might be studied with advantage. For the present purpose, however, it may suffice to merely point out the more important clauses. Article 1, Clause A, authorises the inspection of the preparation and the manufacture of substances intended for food. In many countries inspection only is permitted of objects actually offered for sale, whereas it is the process and methods of manufacture, the utensils and materials employed, which should be carefully watched. Article 2 states that: "The burgomaster and the agents of the Government whose mission it is to see to the execution of the duties prescribed by the present law may freely examine the shops, warehouses and any place whatsoever where alimentary or medical substances are sold during the whole of the time that these places are open to the public. They may also examine during the same hours the depôts annexed to these shops or warehouses, even if these depôts are not open to the public; such places as serve for the manufacture and preparation of alimentary substances destined to be sold, though these places are not open to the public, are equally subject to such visit or inspection, and that at all hours."

This clause embodies a very important innovation. On discussing the matter with some of the authorities the latter expressed the opinion that the clause gives inspectors the right to visit the kitchen of restaurants and see how the food is cooked and whether it is in good condition. It is precisely in restaurants that the law up to the present day has failed to protect the public. Meat, fish &c., when sold in the market, may be in a perfect condition, but when these things have sojourned some time in a high-class restaurant and then, not having been utilised, are sold at a discount to the owner of a cheap restaurant, where they may be kept for some considerable time longer before they are cooked, their condition is far from offering that security to health which they possessed when first purchased. It is now actually proposed to organise a service of inspectors to control and watch the kitchens &c. of restaurants. If resistance is offered to inspection and the taking of samples prevented, a fine of £2 to £3 can be inflicted; and if within the following two years the offence is repeated a fine of £20 can be inflicted, with a term of imprisonment of from eight days to two months. The last clause of the Act is also an innovation and important in its way. It states in Article 8: "Every two years the Government shall present to the Chambers a report of measures it has taken to ensure the execution of this law and the effects that have resulted therefrom." This last clause is a prudent precaution to prevent the law remaining a dead letter. This Act is known as the Law of Aug. 4th, 1890.

The *Moniteur Belge* of Dec. 17th, 1890, contains a report to the King by the Minister of Agriculture, Industry and Public Works, who is the highest sanitary authority in Belgium. This report, dealing with the application of the above law, comments upon the difficulties arising from the trade in margarine, the use of saccharin, of colouring materials and of dangerous utensils and substances for packing, cooking and preserving food and drink. M. Léon de Bruyn, the Minister of Agriculture, in his report, remarks that "it cannot be said public health suffers, for margarine is not in itself an injurious alimentary substance; but the material interests of the consumers suffer, since they pay the price for natural butter and receive in exchange only butter mixed with grease of inferior value. From this it results that our agriculturists also suffer serious injury, for the farmers find that one of their principal products is driven out of the markets by a disloyal competition."

In the same way, with regard to saccharin, though this may not be a poisonous substance, it is a fraud on the public to sell sweets, pastry &c. apparently made with sugar when in reality they are sweetened only with saccharin. In response to this report another law or decree, bearing the date of Dec. 10th, 1890, was signed by the King. This law defines margarine as any sort of butter which has not been manufactured exclusively with milk. Then there follows a stipulation similar to the English Margarine Act, by which all margarine offered for sale must be labelled very distinctly, both in Flemish and in French, with the word "margarine." All cases or barrels containing margarine must also be inscribed with the name and address of the manufacturer. On all bills of lading, invoices &c. the denomination "margarine" must be employed. The same penalties as those mentioned above as the punishment for offering resistance to inspectors apply to any neglect in the observance of those regulations governing the margarine trade.

Another decree, bearing the same date, quotes the opinion of the Royal Academy of Medicine:—"Saccharin is not an alimentary substance, consequently it does not possess for the consumer the useful properties of sugar. It is necessary that the manufacturer or tradesman in substances sweetened with saccharin should inform his customers that he has employed this substance."

On the strength of this opinion the decree orders that all articles—beer, pastry, sweets, liquors, syrups, jams, chocolate &c.—sweetened with saccharin or any similar substance shall bear a large label indicating the fact. That similar announcements shall be displayed on the shops and counters where such objects are sold; and, in fact, the same measures are taken and penalties enforced against the substitution of saccharin for sugar as are enacted to prevent margarine being sold instead of butter. Then follows a third decree by which the employment of any injurious colouring matter in the preparation of articles of food is absolutely forbidden; and all manufacturers selling coloured articles of food, liquors, sweets &c. must affix to such articles their names and addresses. Finally, a fourth decree, also bearing the date of Dec. 10th, 1890, forbids the employment of any utensil, vase, coloured paper &c. in contact with any edible substance if in any way likely to poison such substance. Article 2 states that "it shall be considered as notably harmful and injurious to health and as opposed to the present decree to employ lead, zinc, alloys, soldering, enamels containing these metals, or arsenic, antimony and its compounds, or poisonous colours." Exception is made in the case of tin boxes used for preserves if the soldering is done externally and if the alloy does not exceed 10 per cent. of lead. All apparatus used for cooking purposes, such as metallic and enamelled saucepans &c., must bear in large, ineffaceable characters the name and address of the manufacturer, and it is absolutely forbidden to sell any such utensil if it is made with toxic or poisonous metals &c.

The next law to be noticed deals with the trade in meat. It was published in the *Moniteur Belge* of Feb. 11th, 1891, and is known as the Law of Feb. 9th, 1891. It establishes special enactments to regulate the slaughtering of animals and the trade in meat and poultry. All animals, including pigs, destined to provide butcher's meat must be examined after they are slaughtered by an expert inspector nominated by the communal administration, or, in default, by the Government. Veterinary surgeons are to be selected in preference, but in districts where the services of such qualified persons are not available the expert inspector who is not a veterinary surgeon must call in a veterinary surgeon in all but certain specified cases. Local authorities may also decide that animals shall be examined before as well as after they are slaughtered. A slaughtered animal must be examined not later than twelve hours after its death in summer and twenty-four hours in winter. If the flesh of the animal is unwholesome a written certificate must be given to this effect. If the meat is wholesome various parts of the carcass must be stamped by the inspector. This practice, prevalent in France as well as in Belgium, affords a good and practical guarantee to the public. The purchaser on entering a butcher's shop has only to see if the meat bears the inspector's stamp. The purchaser then knows that the meat has been examined by an impartial and competent authority. When, on the contrary, the meat is condemned, no stamp is affixed, and it must at once be given over to those entrusted by the local authority with the duty of destroying such substances. But if the owner of the meat disputes the verdict of the inspector, he may call in a veterinary surgeon and have a counter-examination. In case of disagreement between the two experts a third expert shall be appointed by the mayor of the locality to decide the matter. The fees and cost of such counter-examination are to be paid by the parties who are ultimately proved to be in the wrong. No cattle are to be slaughtered outside the slaughter-house, except in cases where a horse, mule or donkey has met with an accident that renders its conveyance to the slaughter-house difficult. For horseflesh the inspector shall use a special stamp with the word "horse" distinctly engraved upon it. All meats imported from abroad must come in entire carcasses or half carcasses, but with the lungs adhering. Such foreign meats must be examined and stamped by a veterinary surgeon before they can be sold. A record must be kept and produced whenever required stating who sends and who is to receive the meat in question; and, when such meat is sent from one district to another, the local

authorities may again examine the meat &c. before they allow it to be sold.

A Royal Decree, bearing the date of Feb. 28th, 1891, further elaborates and strengthens the laws mentioned above. The chief purport of this decree is to indicate in a more precise manner what precautions are to be taken to prevent the substitution, the subtraction or addition of some foreign matter to the specimens seized for analysis. The tradesman, by this decree, is allowed to affix his own mark or seal on the sample seized. In the same manner, whenever it is possible, the tradesman may demand that a third sample should be left in his own possession. It is important to note that it is distinctly stated that this shall be done only where possible. There are some things that cannot be divided into three portions, and because such subdivision has not been possible magistrates, in England at least, have refused to convict. Once the sample has been brought to the laboratory the work of the inspector is terminated. The director of the laboratory will proceed to make the analysis, but he will not know whence the sample came. It must only bear a sign, a number by which it can be recognised, and not the name of the person from whom it has been taken. Thus the analyst will escape all accusation of partiality. The articles seized for examination are to be paid for by the local authority if they prove to be unadulterated.

On Feb. 25th, 1891, the Minister of Agriculture sent a circular to the local authorities pointing out that the Government preferred leaving to each locality the organisation of the inspection of meat, unless this duty was neglected, in which case the Government would interfere. The Minister urges that the cost of inspection should be very moderate. In communal or public slaughter-houses the cost, including the inspector's fee, varies from 5*d.* to 1*s.* 3*d.* per 100 kilogrammes of meat. Calculated per head, the following are the maximum and minimum tariffs: For a horse, from 1*s.* to 4*s.*; a bull, 10*d.* to 4*s.* 10*d.*; a bullock, 10*d.* to 3*s.* 6*d.*; a cow, 10*d.* to 2*s.* 6*d.*; a heifer, 10*d.* to 2*s.*; calves, 5*d.* to 10*d.*; pigs or sheep, 5*d.* to 1*s.* 3*d.*; lambs, goats, sucking pigs, 2*d.* to 5*d.* The local authorities must submit their tariffs to the provincial authorities, and these will be sanctioned by the king for a period of five years.

On the 15th of September, 1891, there was a Ministerial circular issued, giving model forms of certificates which veterinary surgeons are to fill up when they inspect meat; and another circular followed on the 26th September, giving advice as to the best methods of destroying condemned meat. On the 10th of January, 1892, and on the 4th of March further circulars followed. These deal more particularly with the internal administration of slaughter-houses, and opportunities of referring to them will occur when describing the public slaughter-houses of Brussels.

Brussels.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *The Recent Case of Hemorrhagic Small-pox in Newcastle.*

It is only right that I should, in the first place in this letter, inform you that at a recent meeting of the Sanitary Committee of the Newcastle Corporation, at which reference was made to the circular of Dr. Whamond of Jarrow criticising the action of our city officer of health with respect to his statements about the recent case of small-pox, it was resolved "that after hearing the allegations contained in the circular, and seeing the certificate given by Dr. Armstrong, the committee were unanimously of opinion that the statement of Dr. Whamond was not correct." There is evidently some mistake in this matter.

### *A New Infirmary for Newcastle.*

The infirmary question has become rather complicated. A meeting was held on Monday night last, presided over by the Mayor, to reconsider the decision come to at a public meeting held in June last at the Guildhall, "that a new infirmary be built upon the present site." The meeting was also one for the promotion of the building of a new infirmary wing in memory of the late Dr. Bunce. The feeling of the meeting was best expressed by the motion of Professor Philipson, which was unanimously accepted—namely, "that having recognised that a difference of opinion exists in the public mind with regard to the site of the new infirmary the whole question be referred to a committee

representative of the infirmary and the general public." At the same time it is felt here that the sooner the public mind can come to a decided opinion on the matter the better it will be for the public and for the general interests of the infirmary.

#### *Sunderland.*

The Heatherdene Convalescent Home, which has been acquired for the Sunderland Infirmary, was opened at Harrogate last Thursday by the Mayoress of Sunderland, Mrs. Stansfield Richardson. The fund, which consisted of several thousand pounds, was the residue of that evoked by the wave of sympathy set in motion by the dreadful Victoria Hall disaster some nine years ago, when some 187 children were suffocated in descending the stairs on the occasion of a juvenile entertainment in the Victoria Hall. It has thus taken a long time to utilise this money, but at last it has been well spent in acquiring this building and grounds at a cost of about £3000. The home will be principally for children, and will be under the direction and management of the committee of the Sunderland Infirmary, and it will also be supported out of the funds of the infirmary.

#### *Miners' Testimonial to their Medical Officer.*

An interesting meeting took place in Eston, near Middlesbrough, last Monday, the occasion being to present Dr. W. Allan Smith, who is leaving the district, with a case of instruments costing over ten guineas. The amount was collected in small sums among the miners and their friends. Several of the miners were on the platform to congratulate the recipient of the testimonial.

Newcastle-on-Tyne, Sept. 21st.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Preparations for Cholera.*

A CIRCULAR LETTER has been issued to the medical men practising in the city of Edinburgh to the effect that amongst the precautions to be taken in view of a possible outbreak of cholera in the city it has been resolved by the Public Health Committee that cases of British cholera and choleraic diarrhoea be required to be notified, in addition to those diseases at present notifiable. The medical officer of health for the city, Dr. Littlejohn, has drawn up instructions for nurses who may be called upon to undertake charge of cholera patients. Last week, at the Queen Victoria Jubilee Nursing Institution, a lecture on Cholera was delivered to about sixty nurses by Dr. John Thomson.

#### *Leith and Cholera.*

Leith has been inspected and reported on by an official from the Board of Supervision. The report has only in part been made public, but so far as its terms are known it shows Leith to be neither well protected against cholera nor fully alive to the critical position she occupies. She has no compulsory notification of disease and she has no infectious diseases hospital. The authorities have taken one wise step in giving the local medical officer an assistant to help in the inspection of ships arriving at the port, and Dr. Purvis has been appointed to attend to this important measure.

#### *The Annual Report of the Scottish Commissioners in Lunacy.*

The thirty-fourth annual report by this Commission for the year 1891 is now in print. On Jan. 1st 1892, there were 12,799 insane persons in Scotland, of whom 10,770 were maintained by the parochial rates, 1972 from private sources and 57 at the expense of the State. As regards the distribution of patients amongst the various institutions, there are no noteworthy points when compared with the preceding year. During the year there was an increase of registered lunatics to the number of 189, 165 of whom were paupers and 24 private patients. The number of persons admitted as voluntary patients has increased, and the Commissioners regard favourably the provision for such cases. The recoveries per cent. of admissions for the year are in Royal and district asylums 35, in private asylums 28, in parochial asylums 42 and in lunatic wards of poorhouses 13. The number of deaths for the year was 152, and the percentage mortality was 9.0 in private patients and 9.6 in paupers. The Commissioners recommend the judicious extension of the provision for allowing patients out on probation. There continues to be a large change amongst asylum attendants, and this, as pointed out in the report, is not favourable to the interests of the patients. There were only 117 accidents

reported during the year, and of these only 11 proved fatal. The Commissioners whose duty it is to visit lunatics accommodated in private dwellings continue to report very favourably on the system. Dr. Fraser says, after fourteen years' experience, that his work has led him "to appreciate the happiness which may accompany humble surroundings, to form a high opinion of the intelligence, integrity and kindness which are to be found amongst the peasantry, and to satisfy myself that, when reasonable care is taken in the selection of patients and of guardians, a large number of the pauper insane who are harmless and incurable can be more suitably provided for in private dwellings than in any other way." The merits claimed for the system are: "(1) home life with its domestic surroundings and interests; (2) individualisation; (3) liberty and contentment; (4) opportunities for remunerative employment or for becoming self-supporting; and these are obtained in conditions favourable to physical well-being and to mental health." The report deals at considerable length with the increased recognition of the importance of hospital accommodation in asylums, and favours the arrangements being made in the new asylums for hospital accommodation for a third of their inmates. The idea in this comparatively new departure is that every patient requiring exceptional treatment, however temporary, should be an inmate of the hospital so long as exceptional treatment is needed. The provision made in the Royal asylums for the reception of the poorer classes of private patients is favourably referred to. As regards the daily cost to a county of its paupers, the Board gives 1s. 1½d. as the lowest and 1s. 9½d. as the highest when they are in asylums, it being lower in poorhouses and private dwellings. Since 1858 there has been an increase in the number of lunatics from 5824 to 12,799. The causes of this increase are discussed at some length, and the Commissioners think that a great variety of causes have co-operated to bring this about, one of which is "the widening of medicine and public opinion as to the degree of mental unsoundness which may be certified to be lunacy." The Commissioners further consider that there is no evidence that any considerable contribution to the increasing mass of lunacy has as yet been made from the wealthier strata of society, from which certified private patients are drawn. The report concludes by various suggestions as to the ways in which the burden of pauper lunacy may be diminished in amount or at least checked in growth.

#### *Health of Aberdeen.*

The medical officer's report for August shows that the death-rate for that month was 15.84 per 1000 per annum, as against 15.47 in July. The average for August during the past ten years was 15.48. There were 63 cases of measles reported during the month, as compared with 116 in the preceding month. The number of cases of scarlet fever during the month was 86, as against 65 in July; whooping-cough 45, as against 82; diphtheria 11, as against 8; typhoid fever 7, as against 6; and typhus fever 4 (one fatal), as against 6. The daily average number of patients in the City Hospital (Fever) was 94.35.

#### *Refusal of Site for the Deer Fever Hospital.*

At a meeting of the Deer District Council of the Aberdeen County Council the chairman announced that the hospital committee had met at Strichen and had agreed as to the construction of the hospital; they had selected an architect and fixed on an excellent site near the Parsonage, Strichen. The proprietor, however, had absolutely refused to allow an infectious hospital in or near the village of Strichen. In these circumstances matters had come to a standstill. Another attempt would be made to obtain the site, and if it were unsuccessful a position might be obtained on an adjacent estate.

#### *Glasgow University Chair of Surgery.*

The appointment of Dr. William Macewen of the Royal Infirmary to this chair, in succession to the late Sir George H. B. Macleod, has given unmixed satisfaction in Glasgow, in lay as well as in professional circles. It is seldom that a State dispenser of patronage has so easy a task as Sir George Trevelyan had in this case, for from the first Dr. Macewen's claims to the post were unquestioned. The University is to be congratulated on having found a teacher who will shed lustre on his *alma mater* and maintain worthily the best traditions of the chair of Surgery.

#### *Medical Education of Women.*

The managers of the Glasgow Royal Infirmary have, as was expected, rescinded their former resolution to exclude women

as students from the wards of the Infirmary, and have decided to afford to female students facilities for clinical and pathological instruction separately from male students. It remains to be seen how this will be received by the fifty-three male students who recently sent in an ultimatum demanding the exclusion of ladies, under threat of withdrawal to some other school. The governors of St. Mungo's College and the directors of the Infirmary are in an awkward predicament. It is really a pity that they departed from their first resolution to exclude ladies. It is quite clear and universally admitted that it is neither practicable nor desirable to carry on the clinical teaching of both sexes in mixed classes; it is also absurd to suppose that the clinical education of women can be satisfactorily carried on in sets of wards set apart for them. To have a thorough, all-round education women must have the same privileges as men—that is, they must have the free run of an entire hospital in all its departments. All the cases suitable and valuable for purposes of instruction cannot be seen in one or two "sets" of wards. The difficulty experienced by Queen Margaret's College students in keeping up their clinical study in an institution so far removed from the scene of their systematic and theoretical work will continue as great as heretofore. The only sensible and permanent solution of the trouble is the adoption of some such scheme as that suggested a few weeks ago in these columns—namely, the amalgamation of the Medical Faculty of Queen Margaret's College with the Muirhead Trust, and the appropriation of their combined funds to the building and endowment of a school near the Victoria Infirmary, to which the entire medical faculty of Queen Margaret's College might be transferred, a proper arrangement having first of all been come to with the governors of the Victoria Infirmary, securing that hospital for the clinical instruction of women exclusively.

#### *Notification of Diarrheal Diseases.*

The Glasgow local authority has issued an order to the effect that British cholera and choleraic diarrhoea are to be regarded as diseases which must be notified on the usual infectious diseases forms, this order to remain in force till the end of November next. This is doubtless in view of the possible appearance of cholera amongst us. Meantime the city remains clear of the disease, the two patients (Russian Jews) who suffered from it a week or two ago having been dismissed well from the fever hospital. The passengers who were associated with these patients were isolated, and all of them escaped the disease.

Sept. 20th.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

#### *Suspected Case of Cholera at Queenstown.*

ON arrival of the Eppleton steamer at Queenstown on Sunday last considerable excitement was created when it was stated that a case of choleraic diarrhoea was on board. The vessel was placed in quarantine, and Dr. Hodges, medical officer for the port of Cork, visited the steamer and found the patient was suffering from choleraic symptoms not of a dangerous character. The case was isolated and removed on the following day to the Queenstown Intercoasting Hospital.

#### *Outbreak of Fever in Kilkenny.*

The county gaol has been closed by sealed order of the Local Government Board in consequence of the epidemic of fever alleged to prevail in the prison. Surg.-Lieut.-Col. Magee has recommended the closing of the James-street police station, inasmuch as several constables have contracted fever and have been removed to the fever hospital—a suggestion which has been adopted by the Urban Sanitary Board.

#### *Kerry Lunatic Asylum.*

The monthly meeting of the board of governors was held last week, presided over by the Earl of Kenmare. The governors had under consideration the appointment of an assistant resident surgeon, as recommended by the Privy Council, at a salary of £100 a year, with rations &c. amounting to about £80. After some discussion the following was adopted: "That the medical superintendent apply, on behalf of the Board, to the Privy Council as to whether, by the new rules 46 and 47, the appointment of a second medical officer is mandatory on the Board before a vacancy occurs in the office of visiting physician."

#### *Suggestions for the Early Treatment of Cholera.*

The Royal College of Surgeons in Ireland have furnished, amongst others, the following suggestions for the use of the public as to the treatment of early or suspicious symptoms when cholera is threatened or epidemic: The College advise no alteration in the habits of living where these have previously been moderate and regular. All excess should be carefully avoided, especially in the use of alcoholic drinks, as it is well known that the intemperate most certainly fall victims to the most fatal type of cholera as of other epidemic diseases. All debilitating causes should be carefully avoided, such as excessive and long-continued fatigue and fasting, overcrowding, exposure to moist, stagnant air, or to air loaded with organic effluvia. During the prevalence of cholera any person affected by any of the following complaints should at once obtain medical advice: (1) Diarrhoea or looseness of the bowels; (2) vomiting or sickness of stomach; (3) pains in the stomach or bowels; (4) pains or cramps in the legs. While such aid is being obtained the patient should be put to bed immediately and warmth should be encouraged by the application of heat to the body and limbs. Also, in case of sickness of stomach, a large mustard poultice should be applied over the abdomen. In the event of cramps ensuing diligent rubbing of the limbs should be resorted to.

Sept. 21st.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *A New Treatment of Oophoro-salpingitis.*

EVERY practitioner is aware of the unsatisfactory means at our disposal (short of abdominal section) for the treatment of the above condition. At the best, in most cases, the patient is relieved of the acute symptoms, leaving the disease in a chronic stage for a weary length of time. Dr. Auvar of Paris announces the successful treatment of two cases by means of intermittent pressure, which he applies in the following manner: A Gariel's air pessary is introduced into the vagina and a bag filled with shot is simultaneously maintained over the site of the abdominal induration. The weight of the shot is gradually increased from 750 to 1500 grammes and the bag is kept applied for from two to three hours every morning and evening. During the interval (the pessary being also removed) hot vaginal injections and a cold enema are administered. In one case quoted, where a very tender swelling the size of a hen's egg could be felt in the right broad ligament, the tumefaction had completely disappeared after ten days of this treatment, and in three weeks the woman was well. In another case of oophoro-salpingitis induced by intra-uterine exploration, internal and external intermittent pressure, by means of a Gariel pessary and a shot-bag weighing one kilogramme, practised once daily for an hour and a half, relieved all the suffering and greatly reduced the swelling.

#### *Toxicity of the Serum in Cases of Eclampsia.*

Puerperal convulsions are now generally regarded as the outcome of auto-intoxication. Bouchard has demonstrated the lessened toxicity of the urine passed, often only in diminished quantity, by such patients. It occurred to Dr. Chambrelent of Paris to supplement these observations of Bouchard by examining the serum of the blood drawn during the attacks. Taking as a basis the fact already established by Rummo that 10 cubic centimetres of healthy human serum is the quantity necessary to kill one kilogramme of rabbit—i.e., 10 cc. to each kilogramme of body-weight—he found that this degree of toxicity was greatly exceeded when eclamptic serum was employed, and that there was a constant relation between the poisonous properties of the serum and the gravity of the case. Six patients were the subjects of the above experiments at the Obstetric Clinic of the Paris Faculty.

Paris, Sept. 21st.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

#### *First Appearance of Cholera.*

THE steamship *Moravia* left Hamburg on Aug. 18th (the day on which cholera was discovered in that city) with 358 emigrant passengers. Cholera appeared on the first day out and con-

tinued to prevail until the ship arrived at this port on the 31st of the same month. The total number of deaths was twenty-two. The vessel is in quarantine, the sick being transferred to one of the islands and the healthy to another. Four days later the *Normannia* and *Rugia* arrived, each having cases of cholera on board, and they were detained in quarantine. New cases are occurring daily at quarantine and all of the vessels are now detained. The result is that the station will soon be overcrowded if the policy of detention be pursued. From Sept. 1st to the 12th no less than 15,000 immigrants were expected to land in the harbour of New York.

#### *Proclamation of Quarantine by the President.*

One of the most extraordinary events in the history of quarantine in this country is the proclamation of a twenty days' quarantine of all vessels from foreign ports carrying immigrants, approved by, and issued under the sanction of, the President. This circular, so called, is the more remarkable because the quarantines at the immigrant ports are all under the exclusive control of the States in which they are situated. Again, an absolute rule of twenty days' detention of all vessels from foreign ports carrying immigrants is an anomaly in our quarantine system, and is, in fact, a return to the practice of the middle ages. It ignores all that we have learned of sanitary disinfection and cleansing, and makes time the chief element in eliminating an infectious disease from ships, persons and baggage. Under this proclamation our quarantines, instead of being aids to facilitate travel and commerce, will become what they formerly were—most annoying and unnecessary obstructions. Indeed, this circular, approved by the President and carrying the weight of his high authority, is very properly introduced as "quarantine restrictions upon immigrations to aid in the prevention of the introduction of cholera into the United States." If carried into effect it will certainly result in stopping immigration, or of overpopulating our quarantine stations with healthy persons.

#### *Quarantine at the Port of New York.*

Fortunately the port of New York, the great entrepôt of immigrants, has a thoroughly organised and equipped quarantine station which is exclusively under the jurisdiction of the State. The laws of this State relating to quarantine have been perfected by experienced medical health officers until they illustrate the most advanced views of sanitary officers. The quarantine station is located on two artificial islands in the harbour, one of which is devoted to the sick and the other to the healthy. Disinfection of baggage and vessels is by superheated steam. Every needed provision is made for the care of the sick, for observation of the healthy and for the disinfection of baggage and vessels. The health officer is clothed with ample powers and at his discretion the entire establishment is managed. He may detain vessels, persons and things one day or one year. As a result of this wise arrangement our quarantine has been regarded by the travelling public, by steamship companies and by commercial men as an aid rather than an obstruction. It has also proved most efficacious in preventing the introduction of foreign pestilences into this country.

#### *General Preparations for Cholera.*

The country was never so well prepared for an epidemic of cholera. Health organisations now exist in every State and municipality and the authorities are unusually well equipped for the work in hand. On every side we hear the note of preparation. Sanitary cleansing extends to every city, town and family. The general public is in a high state of alarm owing to the enormous amount of newspaper reporting, but this alarm leads to precautionary measures and tends to make the people receptive of the advice of health authorities.

New York, Sept. 6th.

## EGYPT.

(FROM OUR OWN CORRESPONDENT.)

#### *Fungous Foot of India.*

SEVEN cases of this tumour, now believed to be actinomycosis, have been seen at Kasr-el-Aini Hospital and were recognised by Mr. Milton from published descriptions of the Madura foot. The first case was that of a young girl seen in 1888, but the remaining six have all been young men, either Egyptians or negroes. The disease has not yet been met with in any other part of the human body or in animals. No light can yet be thrown upon the cause of the disease and only one case has yet shown the black variety of mycetoma.

To the naked eye and under the microscope the Egyptian cases exactly resemble the disease as seen in India.

#### *Resection of Intestine.*

This operation has lately been done here for the first time by Mr. Milton. An Italian woman was operated upon some months ago in a European hospital for strangulated hernia. The gut was gangrenous and an artificial anus was made in the groin and the patient discharged cured. However, she lost weight, and it was easily proved by watching the new anus that it existed too high up in the small intestine to allow complete digestion of eggs and other simple food. After some successful experiments upon dogs the patient's abdomen was opened and the severed intestine clamped, pared freely and sewn together upon a gelatine tube some two inches long.

#### *Alexandria Native Hospital.*

Beyond tents in the desert no accommodation has ever existed in Egypt for infectious diseases, but now a hut for six patients has been constructed in the grounds of the Alexandria Hospital to accommodate such diseases as small-pox, relapsing fever and leprosy. A disinfecting machine, specially modified by Professor Koch, has also been purchased by the municipality. As a proof of the good work done by the hospital staff the number of European patients is constantly increasing, in spite of the presence of several European hospitals, and the 170 beds are always full, even in winter, when the public health is more satisfactory. Natives come from the surrounding towns and villages for treatment. The garden is now very well laid out, and the produce, consisting of peaches, apples, strawberries, mulberries, grapes and figs, is jealously kept for the patients.

#### *Hotel Accommodation in Cairo.*

For the last ten years every winter has seen either some new hotel opened or some existing ones enlarged, and yet for two months at the height of the season Cairo has always seemed over-full. But though there is no lack in the number of visitors, it would appear that enough accommodation has now been provided. Shepheard's Hotel has been completely rebuilt at a cost of £65,000, of which £4000 was expended on sanitary fittings alone. This dry climate permits building to be carried on very rapidly and without any apparent drawback. On April 27th, 1891, they commenced to demolish the old caravanserai so well known to travellers, and the new building was completed between June 7th and Oct. 1st, so that guests were received during October. This celerity was partly aided by electric light and partly by a clause in the contract which fined the builders £70 every day after Sept. 30th. The sanitary arrangements were carried out by an English firm, who employed fifteen English plumbers to fix forty-two v.c.'s, twenty fixed baths, ten slop sinks, two hot-water circulating systems, five urinals and lavatories, and, until the drainage scheme for the town is completed, five cemented cesspools, away from the house, which are emptied by pneumatic tubes. Lifts have been introduced for the first time for passengers, luggage and servants, electric lighting throughout, special ladders for fish, vegetables and poultry; twelve water tanks on the roof in case of fire, and a dozen of Pasteur's filters for all drinking water. Seven European cooks and ten chambermaids are among the 192 servants provided for some 350 or 400 guests. The proprietors have spared no pains to render the new building healthy, and fully deserve the honour of being the first hotel possessed of a sanitary certificate in this country. To prevent all ground damp, some five feet of hydraulic concrete has been used for foundations, besides an asphaltic damp course, and the whole of the garden soil to three feet deep has been changed for clean mould from the bed of the river. The Continental Hotel is having all its sanitary arrangements perfected, and, in addition to a lift and dancing hall, has provided three hansom cabs for the comfort of the guests. The same management is now rebuilding on a new site the Hôtel d'Angleterre, with every comfort for those English visitors who wish to avoid the noise and expense of larger buildings.

#### *Heliouan Hotel.*

The sulphur springs in the desert near Cairo were lately opened up to the public by a new railway line, the owners of which have now started a large and luxurious hotel of two storeys with some 85 rooms for 100 guests. In order to rival existing hotels in Cairo and at the Pyramids, there are electric lighting, English beds and sanitary fittings, lawn tennis, croquet &c. In a detached casino there are reading and billiard rooms, and occasionally balls and concerts are given. Cairo, Sept. 1892.

## NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

*Counter-prescribing.*

AT the last annual meeting of the New Zealand Medical Association the following motion, among many others, was brought forward: "That in the opinion of the New Zealand Medical Association it is undesirable for the members practising in the four large centres in the colony to dispense and send out medicine from their houses, except in cases of emergency. Further, that in the opinion of the Association such a practice is not necessary in the interests of patients, and that its tendency is to lower rather than to raise the status of the profession in the colony." Counter-prescribing is very plentiful in New Zealand. As a matter of fact, medical men here are, in some of the leading centres, compelled to prescribe and dispense their own medicines for their own protection. Now what has brought this state of things about, and how is it to be remedied? Let us look at it from the chemist's point of view. He says he is almost compelled to prescribe over the counter, because as a business man he is called upon to cater for the wants of the public, and because certain sections of the public will not call in a medical man until the patient appears to be *in extremis*. Again, he has an active antagonist in the shape of the herbalist, who is ready and willing to prescribe and dispense for any and every complaint, and there is no law to prevent the quack, who has received no training and passed no examinations, from doing so. Under these circumstances the chemist states that if he refused to prescribe and referred his customer to a physician, he would in all probability find his customer emerging from the herbalist's with a supply of medicine. It can be laid down as a maxim that the more ignorant the quack the more he endeavours to gull his customers. It is a fact that some five years ago there was exposed for sale in a herbalist's window in a leading thoroughfare in a principal town in New Zealand a bottle labelled "Medesin' for Sekret diseases." Within the last few months another herbalist dubbed himself M.B., and explained that it represented "Medical Botanist." The herbalist is ignored. Further, it is stated that medical men by prescribing and dispensing their own medicines compel chemists to prescribe, since if they did not do so they would only have the sale of the patent and proprietary medicines as a means of livelihood to fall back upon. The only means of remedying the present very unsatisfactory state of things is to pass an Act introducing the German mode of conducting medicine and pharmacy; but such an Act is not likely to be brought forward in this colony at the present time. I feel that dispensing is degrading to the profession, for in the majority of instances the patient is under the impression that it is the medicine he is buying from you and not your advice and consideration of his case. In a district where medical men reside who do not dispense their own prescriptions there is no possible excuse for a chemist to act as a consultant. I should like to see the New Zealand Legislature take the initiative and adopt some such general principles as those which seem to work so well in Germany.

*Leprosy among the Maories.*

A very interesting article from the pen of Dr. Martin of Wellington appears in the July number of the *New Zealand Medical Journal*. It describes two undoubted cases of leprosy, and does much to decide the many contradictory opinions which exist as to the prevalence of the disease among the Maories. Two cases are described: those of a full-blooded male Maori, aged about forty, and his nephew, aged about fifteen. The elder patient was, according to the natives, supposed to have been bewitched by a Maori who had acquired this evil power from a "tohunga" who was proficient in the art and who lived on the borders of the Hauraki gulf. The cause of his exercising this power was due to a quarrel, and they state that the malady soon developed—in fact, would have one believe almost immediately. The onset was numbness of the extremities, ending in complete anaesthesia with coincidence of lumps through the skin. Dr. Martin describes in detail the present condition of these two lepers, which goes to show that this disease exists among the Maories in the immediate vicinity of the hot lakes. The family history of these cases shows that neither in the parents nor in their ancestors had the disease appeared. Case 1 had lost two brothers from natural causes; one brother and a sister (mother of Case 2) died lepers, while

one sister is alive and well at Wanganui. The Maories call the disease "ngeri-ngeri"; they state that the illness has been handed down by tradition and are rooted to the conviction that it is caused by witchcraft. The malady in the case of the boy arose, according to the natives, from his partaking of some food from a lying-in woman during the time prohibited by Maori law. Another fertile source of the complaint is the act of urination over graves, which is looked upon as a terrible breach of Maori observance. Dr. Martin ends his very able article by the remark "that leprosy in the true form exists there can be no doubt, but it is to a very limited extent and very little would be required to stamp out the disease now; but what with drink and debauchery matters may assume greater proportions and call forth greater exertions for its extirpation."

## Obituary.

ALFRED LEACH, M.B. ABERD., M.R.C.P. EDIN.

THE death of Dr. Alfred Leach may be looked upon as another instance of a member of our profession sacrificing his life in the performance of duty. The immediate cause of his death was a severe attack of English cholera, which commenced on Sept. 11th and ended fatally early on the morning of Sept. 14th. The exciting cause is believed to have been due to the inhalation of sewer air while investigating the cause of an outbreak of diphtheria in the house of one of his patients. It was two days after this that he first began to complain of diarrhoea and sickness. Thinking too lightly of these symptoms he would not have any professional aid till cramps began to appear thirty hours after the onset of the disease. The cramps were soon followed by symptoms of collapse, a feeble, intermittent, thready pulse, cold hands, cold perspiration, and sunken features. The diarrhoea and sickness were checked, stimulants and nourishment were taken and were retained in considerable quantities. Yet the state of semi-collapse never yielded, and despite the constant attention of his medical friends, Dr. Dewar and Dr. Ewart, and the assistance of Mr. Pearce and Mr. O'Donnell, the case terminated fatally twelve hours after the cessation of the sickness. The poison, acting on a constitution never robust, caused several attacks of dyspnoea, accompanied by loss of vision and excitement. The inhalation of oxygen greatly relieved these symptoms. One fact worthy of notice is that, in spite of the weak, thready pulse, which often could not be counted (though after the inhalation of the oxygen it was steadied and strengthened), death commenced at the lungs, for the heart was beating when respiration had ceased. In disposition Dr. Leach was gentle and considerate, and in all his dealings most honourable. He had no professional jealousy or meanness, but always showed scrupulous regard for the rights and the feelings of his *confrères*. In consequence he was a great favourite with his professional brethren and with his patients. He will be missed by many friends, rich as well as poor. Although Dr. Leach did not contribute much to medical literature he was possessed of fine literary qualities, and during his student days in Aberdeen he published a little book on the "Letter H" and one of poems called "The Quadrangle by Moonlight." In those days the Muse was more to him than Medicine. He was a good linguist, speaking Arabic, Italian and French. He has held for several years the post of physician to the Italian Hospital, and was only thirty-five years of age at the time of his death.

## PAOLO FIORDISPINI.

Few of the many English-speaking physicians who have visited Rome but must have made a pilgrimage to the great lunatic asylum in the Trastevere and formed the acquaintance of its highly accomplished and efficient superintendent, Dr. Paolo Fiordispini. In that institution and under his guidance they must have noted, as they passed from ward to ward, the admirable surveillance exercised over the patients, the almost total absence of all mechanical restraint and the general air of tidiness, cheerfulness and order that prevailed. If, after having made the round of the vast asylum, they accompanied their courteous host to the neighbouring heights

of the Janiculum, where villas are established amid charmingly rural surroundings for the convalescents, they must have found in the new series of arrangements for the treatment and comfort of the inmates enhanced evidence of the forethought, the knowledge and the skill which presided over every detail of the management; and on taking leave of their painstaking and experienced guide they seldom failed to receive from him, along with his hearty "a rivederla," a copy of his latest report, in which they might read an excellent digest of the *movimento* of the institution within its last statistical period, and derive the pleasure that a lucid and at the same time rigidly scientific narrative of disease in its incidence, its progress, its treatment and its issue invariably confers. To all such and to a large circle of the profession, particularly in its medico-psychological department, the news of Dr. Fiordispini's death will bring sincere regret. A Roman by birth and education, he was born in 1834 and early attracted the notice of his teachers by his quiet energy, his unobtrusive intelligence, his high standard of worth, intellectual and moral, and his great suavity of address. The study of the obscurer diseases of mind and brain had always a special fascination for him, and he was signally aided in its prosecution by one of his predecessors in office, Pope Pius IX.'s body physician, who recalled the best traditions of Valsalva and Lancisi, Dr. Viale-Prelh. Comparatively early in life he won the object of his ambition—the superintendence of the great lunatic asylum in whose service he lived and died. The Manicomio in the Trastevere, situated in the Via della Lungara, at that picturesque bend of the Tiber where it shortly leaves the city to wind wearily through the melancholy and mysterious Campagna to the sea, owed much to Pius IX., under whose enlightened patronage it was one of the first asylums in Europe to dispense with the shackles, the strait waistcoat, the "bath of surprise" and the other antiquated instruments for the coercion of unruly patients. The Holy Father found in young Fiordispini an able and sympathetic interpreter of his wishes; one who by travel or correspondence had made himself acquainted with the best doctrine and practice to be found in Europe for the care and cure of the insane. Together, Pontiff and physician, they conferred and deliberated for years to improve the institution, and the successive additions to its resources and improvements in its working were embodied in those "Rendiconti Statistico-Clinici" which came to be anticipated with eagerness and read with pleasure and profit by the medico-psychologists of Europe. When in 1878 Pius IX. died, his successor Leo XIII. maintained the same friendly and even affectionate relations with Dr. Fiordispini, and again reforms and ameliorations in the institution were being steadily introduced when the health of their devoted adopter or promoter began to give way. Still he struggled on against advancing debility of bodily and even mental power till he had to retire to Castel Gandolfo, the summer residence of the Popes on the Alban hills, for rest and mountain air. Improvement was at first manifest, but the thirty years' continuous strain in superintending the vast Manicomio was not to be overcome. On the 29th ult. Dr. Paolo Fiordispini, at the comparatively early age of fifty-eight died surrounded by his family and sustained by the presence of friends, medical and ecclesiastical, professional and lay. His remains, in a coffin covered with wreaths from sympathisers far and near, were borne by the villagers of Castel Gandolfo to the neighbouring church of S. Thomas of Villanuova, which overhangs the beautiful Alban lake. A more elaborate funeral service has yet to be celebrated, at which many of the public, including colleagues in professional and civic office, members of learned bodies and "cavalieri," like himself, of the "Crown of Italy" and of other orders have signified their wish to attend.

THOMAS AITKEN, M.D. EDIN.

GREAT grief was occasioned in Inverness on Monday, the 12th inst., by the news of the death of Dr. Aitken, Physician and Superintendent of the District Lunatic Asylum, at the age of sixty. Dr. Aitken had not been for some time in robust health, but he was travelling on the Continent when he caught a chill and died suddenly of bronchitis. His high character and his long connexion with the northern asylums, extending over thirty years, gave this news a distressing effect. Dr. Aitken graduated at the University of Edinburgh in 1858, having written a thesis on General Paralysis of the Insane. He was not only a high authority on mental disease,

but a man of high general and literary culture. He was a member of the Landward School Board, Inverness. He was a botanist of some eminence, and had made a fine collection of the flora of the district, and contributed papers on the same to the Transactions of the Inverness Scientific Society. He was a genial and much-esteemed friend. In 1861 he married Miss Torrie, daughter of Dean Torrie of the Diocese of St. Andrew, and granddaughter of the late Bishop Torrie, Dr. Aitken was a native of Dumfries.

## Medical News.

**PRECAUTIONS AGAINST CHOLERA.**—It is stated that the Corporation of London have decided to make some very substantial and necessary additions to their hospital at Gravesend.

**DRAINAGE AND WATER SCHEME FOR HENLEY-IN-ARDEN.**—The Stratford-on-Avon Sanitary Authority have directed their clerk to authorise Mr. J. E. Wilcox, C.E., of Birmingham, to prepare a general drainage scheme for Henley-in-Arden.

**DEATH OF HOSPITAL NURSES IN PARIS.**—M. Laurent of the Municipal Council of Paris, is reported to have said that nurses and ward attendants are so badly paid that they can only be recruited from "saintly heroines and the scum of the population who cannot get other employment."

**YORKSHIRE COLLEGE.**—A residential hall for the convenience of students attending the above college is now on the point of completion. Its appointments appear to be very elaborate, and the structure will be known as Lyddon Hall.

**SURGEON-MAJOR LEES-HALL,** who worked so hard in the cause of ambulance in Colombo some three years ago, is now following up his work in Halifax, N.S. The police force have already two classes amongst them, and four other classes are being formed amongst the militia and firemen.

**DEATH OF DEPUTY SURGEON-GENERAL G. W. POWELL.**—An inquiry concerning the death of Deputy Surgeon-General G. W. Powell was held on the 19th inst. by Dr. Danford Thomas. The deceased gentleman died from a fall consequent on a false step made whilst looking in a shop window; but the necropsy showed disease of several organs of the body, and that death was due to syncope.

**NEW INFIRMARY, SOUTHPORT.**—It has been decided to invite the Mayor of the borough (Alderman G. A. Pilkington, M.R.C.S., who twenty-one years ago was the first house surgeon to the present infirmary) to lay the foundation stone of the new infirmary on Oct. 29th. The new building will cost upwards of £13,000, exclusive of the site, comprising five acres, which has been presented.

**FOOTBALL CASUALTIES.**—During a match on Saturday between the captains' teams of the Nuneaton Town Football Club a player sustained a fractured leg. On the same day a member of the Harrogate Football Club, aged twenty-three, in a match between the Harrogate and Stanningley teams, collided with another player and received injuries, from which he died on the following day; and on the same day, in a match at Pateley Bridge between the Local and the Harrogate St. John's Clubs, a player aged twenty-four fractured his clavicle and was removed to the Leeds Infirmary.

**CORONERS AND THEIR JURISDICTION.**—At the close of an inquest at Warrington on the 16th inst. on the body of a man who died from a fall at Knutsford-road, Mr. Brighouse, the county coroner, explained that he was there simply to prevent a scandal, and not because he thought he had any legal right to be amongst them, although he had no objection to meet a Cheshire jury. The Local Government Act was passed in 1888, and that was the Act of Parliament on which Mr. Yates, the Cheshire coroner, relied in support of his contention that he (Mr. Brighouse) ought to hold that inquest and not himself. Mr. H. C. Yates has explained that it was only recently he had been instructed by the clerk to the Cheshire County Council that Latchford had been transferred to Lancashire. He naturally concluded that the Lancashire County Council had communicated at the same time with Mr. Brighouse, their coroner, and he was therefore astonished that the report of the accident in Latchford should have been sent to him.

**SCARLET FEVER IN LEEDS AND OVERCROWDING.**—Great efforts are being made by the Corporation to extend the hospital accommodation in this borough. The Beckett-street Hospital has already 100 beds occupied.

**THE NEW FEVER HOSPITAL AT TOTTENHAM.**—Great exertions are being made to complete the erection of this hospital as rapidly as possible. On Monday 800 men were at work. The "huts" are 100ft. long by 25ft. wide and are made of boards lined in between with felt. The estimated cost is £40,000.

**THE TREATMENT OF "CASUALS."**—An order having been issued by the Local Government Board authorising boards of guardians to admit applicants to the casual wards to be discharged early next morning without performing any work, the Lambeth Board of Guardians have adopted a resolution the result of which is that the applicants will be discharged at 5 30 A.M. and food given to them before departure.

**NEW SEWERAGE WORKS AT WEYBRIDGE.**—The inhabitants of Bysfleet have held a meeting protesting against the new sewerage works for the parishes of Weybridge, Oatlands and Hersham. It was unanimously resolved to resist the scheme by every available means, on the ground that the proposed site in Oyster-lane would seriously affect all classes in the village for people would not care to live in the neighbourhood of a sewerage farm, while it was held that the flooding of the Wey would force the sewage backwards into the village and probably cause an epidemic.

**THE DANGERS OF IMPORTED CARPETS.**—At a meeting of the Kidderminster Town Council the chairman declared that the carpets imported from the East, and purchased for the adornment of fashionable homes, often contained the germs of infectious disease. The Government had prohibited the importation of rags from the East as calculated to spread cholera, and Eastern carpets ought to be similarly tabooed. It was well known in the trade that when bales of such carpets were opened, clouds of ill-smelling dust were emitted, and the men engaged in unpacking suffered from violent purging and vomiting.

**SOCIETY FOR PROMOTING UNIVERSITY REFORM.**—On Wednesday, the 28th inst., a public meeting will be held at the Memorial Hall, Farringdon-street, when resolutions to the following effect will be submitted:—1. That in the interests of middle-class education the Greek language be removed from the list of compulsory subjects for degrees at our national universities. 2. That the eighteen months' university teaching required for the B.A. degree be spread over two years instead of three as at present. 3. That reform is urgently needed in the governing body of our national universities, as the present predominating power of the Theological Faculty tends to obstruct proposals brought forward in the interests of other branches of study essential to modern times.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

**ANCRUM, G. WAYLAND, M.B., C.M., L.R.C.S., L.R.C.P. Edin. & Glasg.,** has been appointed Assistant House Surgeon to the General Infirmary and Eye Institution, Gloucester.

**BERRY, JAMES, B.S. Lond., F.R.C.S.,** has been appointed Surgical Registrar to St. Bartholomew's Hospital, vice C. B. Lockwood.

**BLUETT, JOHN, M.R.C.S.,** has been reappointed Medical Officer of Health for the Borough of Chesterfield.

**DIXON, W., M.B., C.M. Edin.,** has been appointed Medical Officer for the Second Hougham Sanitary District of the Dover Union.

**EATON, JAMES, M.R.C.S., L.M.,** has been appointed Medical Officer for the Spittlegate Sanitary District and the Workhouse of the Grantham Union.

**EDGE, FREDERICK, M.D., B.S., B.Sc. Lond., F.R.C.S. Eng.,** has been appointed Honorary Acting Gynaecological Surgeon to the Wolverhampton and District Hospital for Women.

**HEWITSON, C. C., M.R.C.S.,** has been appointed Medical Officer for the St. John's Sanitary District of the Weardale Union.

**HOLMAN, H. C., M.R.C.S.,** has been reappointed Medical Officer for the No. 2 Sanitary District of the Hallsham Union.

**HOSKINS, E., M.R.C.S.,** has been reappointed Medical Officer for the Little Eaton Sanitary District of the Shardlow Union.

**IRWIN, STEWART, M.B., B.Ch. Irel.,** has been appointed Medical Officer for the Almondsbury Sanitary District of the Thornbury Union.

**LOWNDS, H. A., L.R.C.P., L.R.C.S. Edin.,** has been appointed Medical Officer for the Workhouse of the Doncaster Union.

**MOON, D. S., L.R.C.P., L.R.C.S. Edin.,** has been appointed Honorary Consulting Surgeon to the Royal Infirmary, Dundee.

**NICKLIN, M., M.B., L.R.C.P. Lond., M.R.C.S.,** has been appointed Honorary Assistant Surgeon to the Wolverhampton and District Hospital for Women.

**SMITH, PATRICK A., M.B., C.M., F.F.P.S. Glasg.,** has been appointed Visiting Physician to St. Peter's Seminary, Bearsden.

**STONHAM, H. A., L.R.C.P. Lond., M.R.C.S.,** has been appointed Medical Officer for the Out-door Poor of the Stenney Union.

**WILSON, ARTHUR MARIUS, M.B., B.S., L.R.C.P., M.R.C.S.,** has been appointed Assistant Medical Officer of Health (tempora y) to the Port of Colchester, to inspect all incoming vessels.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement.*

**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Pathologist.** Salary 100 guineas per annum. (Applications to the Secretary, 24, Finsbury-circus, E.C.)

**CLAYTON HOSPITAL AND WAKEFIELD DISPENSARY, Wakefield.—Junior House Surgeon.** Honorarium £40 per annum, with board, lodging, and washing.

**HOLBORN UNION.—Resident Medical Officer of the Workhouse, Shepherdess-walk, City-road, N.** Salary £200 per annum (to include midwifery fees if called upon to act), with furnished residence, gas, coals and washing. £60 per annum required towards the cost of his rations. (Apply to the Clerk to the Guardians; Offices, Clerkenwell road, E.C.)

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physicians.**

**HOSPITAL FOR WOMEN (THE LONDON SCHOOL OF GYNÆCOLOGY),** Soho-square, W.—Clinical Assistants.

**KENT AND CANTERBURY HOSPITAL.—Assistant House Surgeon.** Salary £50 a year, with board and lodging.

**LANCASHIRE COUNTY ASYLUM, Rainhill, near Liverpool.—Pathologist.** Salary £200 per annum, with furnished apartments, board, attendance, and washing.

**ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—House Physician for six months.** Salary at the rate of £40 per annum, with board and lodging.

**ST. PETER'S HOSPITAL FOR STONE AND URINARY DISEASES, &c., Henrietta-street, Covent-garden.—House Surgeon for six months.** Honorarium 25 guineas; board, lodging, and washing.

## Births, Marriages and Deaths.

### BIRTHS.

**DREW.**—On Sept. 16th, at Broad-street, Oxford, the wife of Arthur J. Drew, F.R.C.S., of a son.

**GARLICK.**—On Sept. 15th, at 3, Gordon-square, the wife of George Garlick, M.D., of a son.

**MARTIN.**—On June 24th, at Ootacamund, India, the wife of Brigade-Surgeon-Lieut.-Col. P. R. Martin, of a daughter.

**WARD-HUMPHREYS.**—On Sept. 18th, at Oriel Lodge, Cheltenham, the wife of G. H. Ward-Humphreys, L.R.C.P. Lond., M.R.C.S., of a daughter.

### MARRIAGES.

**BICKERSTAFF—GREENWOOD.**—On Sept. 15th, at St. Clement Dane's, Strand, George Roger Bickerstaff, L.R.C.P. Lond., M.R.C.S., of Waltham Abbey, Essex, younger son of the late Rev. J. Bickerstaff, Rector of Bonsall, Derbyshire, to Grace Catherine Greenwood, elder daughter of the late Rev. H. B. Greenwood, Rector of Sutton-upon-Arden, Yorkshire.

**BOON—MATTHEWS.**—On Sept. 14th, at St. George's, Bloomsbury, by the Rev. H. R. Hawsel, M.A., Incumbent of St. James's, Marylebone, Ernest Gerald Boon, L.R.C.P. Lond., M.R.C.S. Eng., of St. Kitt's, West Indies, to Frances Amy, daughter of the late I. N. Matthews, of Buffalo, New York, United States.

**KEYS—WELLS—LOWNDES.**—On Sept. 21st, at Little Comberton, Worcestershire, by the father of the bride, assisted by the Rev. E. J. Rhoades, M.A., Rector of Elmley Castle, Ernest Neville Keys-Wells, M.B., fourth son of the Rev. William Keys-Wells, M.A., of Sarony-square, Scarborough, to Grace Eleanor, younger daughter of the Rev. Edward Spencer Lowndes, Rector of the parish.

**MACEVOY—HART.**—On Sept. 17th, at St. Philip's, Batterssea, Henry John Macevoy, M.D., B.Sc. Lond., M.R.C.S., L.R.C.P., of 41, Buckley-road, Brondesbury, N.W., to Mabel, youngest daughter of the late George Hart, of Wakefield, Yorks.

### DEATHS.

**COTTER.**—Recently, at Cheadle-Hulme, Cheshire, the Rev. J. L. Cotter, M.D. Dub., M.R.C.S.

**HUGHES.**—On Sept. 16th, at Bedford House, Deal, David Hughes, M.R.C.S., aged 51.

**LEACH.**—On Sept. 14th, at 21, Belgrave-road, S.W., after three days' illness, Alfred Leach, M.B., M.R.C.P., aged 35 years.

**NICHOLSON.**—On Sept. 14th, at Surrenden, Queen's-park, South Norwood, Brinsley Nicholson, M.D., aged 60.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages and Deaths*

## METEOROLOGICAL READINGS.

## Medical Diary for the ensuing Week.

## Monday, September 26.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.  
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.  
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.  
 CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30 P.M.  
 HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.  
 METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.  
 ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.  
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.  
 UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

## Tuesday, September 27.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.  
 GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.  
 ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.  
 ST. MARK'S HOSPITAL.—Operations, 2 P.M.  
 CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.  
 WESTMINSTER HOSPITAL.—Operations, 2 P.M.  
 WEST LONDON HOSPITAL.—Operations, 2.30 P.M.  
 ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electrotherapeutics, same day, 2 P.M.

## Wednesday, September 28.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.  
 MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.  
 CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.  
 ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.  
 LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.  
 ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.  
 SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations 2.30 P.M.  
 GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.  
 ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.  
 CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

## Thursday, September 29.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

## Friday, September 30.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

## Saturday, October 1.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

## Notes, Short Comments &amp; Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

## A HUMAN "SUBJECT" FOR CHOLERA EXPERIMENTS.

A LADY CORRESPONDENT writes to us that she believes that "M. Pasteur is practically at a standstill in his experiments with anti-choleraic vaccine; for though having proved its inoculation ensures immunity from the disease to animals that are open to choleraic infection, yet to conclusively prove its value as a safeguard to humanity against cholera it is necessary not only to vaccinate a human being with anti-choleraic vaccine, but subsequently to test its efficacy by administering a dose of the cholera poison itself." Having stated so much, our correspondent suggests that a voluntary subject is wanted upon whom to make the final experiment, and adds: "The cause of this letter is just to inform you that if I may be allowed I have a wish to offer myself as a voluntary subject for the required test, in the hope that thereby a means may be firmly established to obliterate a pestilence." We regret that we cannot accede to our correspondent's request that we should be parties to such an experiment, which would by no means determine the question. Moreover, the institution of such a class of experimentation is strongly to be deprecated.

F. B. (Queen's Gardens) is thanked for kindly furnishing us with a copy of the late Dr. Archibald Billing's pamphlet on the nature and treatment of cholera. Dr. Billing was a learned physician, and occupied a distinguished position as a professor and medical writer, and any observations of his merit attention; but we fear that the treatment he inculcated, on the assumption that cholera was a species of fever, will not be followed in the present day. The truth must be confessed that there is no drug or any combination of drugs known to medicine that can cure cholera.

W.—We do not publish lay opinions with reference to any drug. Our correspondent should accept the "authority" of his usual medical attendant on the subject.

L.R.C.P.E. (Downpatrick) should apply to the Home Secretary, marking the department concerned in the corner of the envelope.

Mr. James Gray.—We are glad to see that our recommendation has been adopted.

Mr. F. Lawrence.—The communication has already appeared in the lay press.

## FEES IN POLICE CASES.

To the Editors of THE LANCET.

SIRS,—In March last, during the strike riots here, I was called out by two women to attend a man in the custody of the police, who, in trying to escape, had got struck on the head and was rendered unconscious. I was with him for over two hours and then saw him conveyed to his own home and attended him for over a fortnight. At midnight on the same night the chief constable of the district and the inspector called and took me to a man who had his head cut open by a brick. I stitched up the wound and saw him next day, and he called at my surgery some days later when the wound was healed. The chief constable of the county and the chief constable of the district called on me during my surgery hours and learnt all I had to say about the accidents to both men. I was not called to the trial, but what I told the chief constable was quoted. In April I sent in a bill, addressed to the chief constable of the district, of 2½ guineas for my attendance, consultations, &c., but no notice whatever has been taken of it. Before sending in another bill this quarter I should like to inquire whether I am entitled to my fees, and if so, to what amount and to whom I should apply for them.—I am, Sirs, yours truly,  
 Sept. 10th, 1892.

M.R.C.S.

## QUESTIONABLE MEAT FOR SALE AT BIRKENHEAD.

WE cannot find room for the publication of the notes of the evidence in this case. It is unsatisfactory to find a magistrate accepting the evidence of butchers, including that of the owner of the beast in question, in preference to that of the inspector, of medical men, and of a veterinary surgeon. But it is a question for discussion in the local papers.

*Hypnosis.*—We are not prepared to advise the practice of hypnosis or to recommend the names of its practitioners. The subject is one of very great difficulty and much difference of opinion exists regarding it. As regards the mode of inducing hypnosis and the general phenomena of the state the fullest particulars will be found in such works as those of Moll, Bernheim, Forel, Wetterstrand, Lidgöols &c. A cheap translation of Moll's work has been issued in the International Scientific Series and probably this would suffice for the needs of our correspondent.

*Mr. Potter.*—Technically, and even legally, the practitioner is entitled to his fee. But it is a matter for the discretion of the practitioner how far he will go in claiming it or any portion of it. He should, we think, either claim the whole or none.

*Subscriber since 1866.*—The claim should not be legally pressed. Notice should have been given of increased fee.

*Mr. Philip W. G. Nunn* is thanked for his report, which shall have our early attention.

*S. W. Dublew* should have repeated his query in his second communication.

## WANTED A DIAGNOSIS.

To the Editors of THE LANCET.

SIRS,—As I am not at all clear about the diagnosis of the following case, which I treated as one of gall-stone, I should be thankful to know from some of my professional brethren how they would interpret the symptoms I am about to describe:—

On the 11th inst. I was called to J. W.—, a discharged soldier, aged thirty-five, who complained of intense pain and tenderness in the lower sternal, epigastric, and right hypochondriac regions, with frequent vomiting of a light yellow fluid. I was informed that as the patient was going upstairs on the previous evening he was suddenly seized with a pain across the chest, especially over the heart, which "seemed ready to burst." This continued till 3 A.M., when he went to sleep. He awoke about 6 o'clock and immediately commenced to vomit. The pain had moved more to the right hypochondriac region, and ceased about midday. The vomiting, however, which was very distressing and profuse, continued till 9 at night and then stopped suddenly. The patient continued to improve, and was about in a few days. There was no jaundice. A peculiar feature in the case was that for about six days previously to the attack the patient had noticed that movements of his tongue, such as drinking, sucking, or spitting, were painful, although on examining the tongue there was no appearance of soreness. On the subsidence of the acute attack above described this soreness of the tongue was found to have quite gone. Some years ago, while stationed with his regiment at Hong-Kong, the patient tells me he had a severe attack of hepatitis.

I remain, Sirs, yours truly,

Sept. 20th, 1892.

L.R.C.S.I.

## THE CARRIAGE OF VACCINE LYMPH BY CARRIER-PIGEONS.

SURGEON-MAJOR STREBEL, at a recent meeting of the Académie de Médecine, showed the possibility of transmitting six small tubes of vaccine lymph over considerable distances by carrier pigeons.

*Spes.*—The relations described would be very liable to render the medical man open to the charge of "covering." They should not be entered into.

*Conjoint.*—We see no objection to adding to the titles the source from which they were derived, as suggested.

*Microphone* asks to be informed where he could purchase a microphone suitable for auscultation.

*Mr. J. G. Campbell* (Belfast).—A brief notice of the rarity might be interesting.

*Brigade-Surgeon Renton* (Eyemouth) is thanked for his communication.

## HEALTH OF ROUMANIA.

To the Editors of THE LANCET.

SIRS,—The health of this port and of the Danubia in general continues excellent. A few cases of diarrhoea occur amongst adults, attributable to indulgence in melons, grapes and other fruits. Infantile summer diarrhoea exists, but in a mild form and rarely fatal. In the Adenbrul daily paper of the 23rd inst. it is reported that cholera has appeared at Cornanti, a town on the Roumanian frontier near to Buceavina. There is no other news to report, beyond stating that up to the present there does not exist anything indicating an approach of the malady to this district.

I am, Sirs, yours truly,

Constanta, Kustendjie, Sept. 6th, 1892. A. IRWIN BOLTON, M.B.

## BASHFULNESS AND ITS NEUROTIC RELATIONS.

THE quality of modesty has in all times commanded the respect of thoughtful and sincere persons. In it we recognise one of the most familiar marks of a genuine character and we should be very doubtful if, other things being equal, it has ever really stood in the way of its possessor's advantage. Where it has appeared to do so we may safely say that it has been represented by some spurious imitation, or, if present, has been associated with personal failings which ought really to bear the blame too lightly attributed to its operation. Of its imitators we may select one as an example—bashfulness. So closely do these two qualities approach one another at certain points that the distinction between them is almost lost sight of. Yet there exist essential points of difference. Both agree in avoiding prominence, but in the case of the former this is due to a humble estimate of personal capacity and an unselfish preference of others, and it is compatible with the free expenditure of effort when occasion demands this. With bashfulness it is different. Self-consciousness is here the commanding influence, and this is by no means a necessary counterpart of self-abasement. Want of acquaintance with existing social conditions is allowed to assume an exaggerated importance. There is a disinclination to abandon a resulting attitude of habitual reserve which even the claims of mutual duty which bind together members of the social whole are unable to overcome. We do not forget that a neurotic basis often underlies this inveterate shyness. The blush, the changing expression, and a variety of like indications clearly denote this. There is doubtless a mental hyperæsthesia which is congenital and therefore the less amenable to treatment. Even this, however, is but a functional condition and therefore not incurable. What is required for its relief is the steady exercise of a dominant control acting through nerve centres at the instance of the will. No good is done by closely contemplating the disorder, but the cure follows most surely when personal peculiarities are ignored, and when even identity is sunk in a sense of dutiful relationship with others. A habit of concentration upon work and the cultivation of free social intercourse constitute the most obvious aids of the will-power in this matter.

*Z. J.*—It is certainly the duty of the medical man first called, on detecting the case, to notify, and, unless the first was acting distinctly as *locum tenens* for the second, it will be right for the second also to do so. It seems superfluous; but the Act says: "Every medical practitioner . . . shall send to the medical officer of health," &c.

*W. L. S. (Buxton)* is thanked for the copy of the pamphlet by a late member of the Indian Medical Staff who was sent by Government and appointed Physician-in-Chief to the Cholera Hospital in Warsaw during the epidemic of that disease in 1830.

*Medicus.*—There would be no breach of professional etiquette in our correspondent intimating to his own patients on a card his change of address. It would simply be an act of courtesy and convenience.

## "MIDWIVES' REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent, Mr. Ramsey, allow me to say there can be no objection to stating on the death certificate such a fact as "delivered by a midwife." I have always done so, and even in the case mentioned in my letter in your last issue (p. 696) in certifying it to the medical officer of health I did, and also added to the certificate "no doctor was engaged." Such information is practical and useful.

I am, Sirs, yours truly,

Sept. 17th, 1892.

FREDERICK F. ALDERSON, M.D.

## INCINERATION OF CHOLERA STOOLS.

A CORRESPONDENT wishes for information as to the probable minimum cost of an efficient apparatus for incinerating cholera and typhoid fever evacuations &c., in connexion with an infectious hospital.

*Enquirer.*—He breaks no law by using the title. He is already registrable and registered. The use of the title in question is a matter of taste. If our correspondent is satisfied with its source and character he will be justified in using it so long as he does not represent it as implying a British degree.

*Mr. Alfred Ford.*—Such an institution should appoint a qualified dispenser, because the law requires those who dispense medicines to be qualified, and the law is a proper one.

*Mr. E. Clendon.*—Such communications should reach us through a medical practitioner.

*Mr. J. B. Chatterton* should seek the information from his regular medical attendant.

ERRATUM.—In Dr. Alderson's letter on the subject of "Midwives and Abnormal Cases" (page 696 of our last issue), twenty-sixth line from the commencement, for the word "few" read *poor*.

# EXCELLENCE IN PHARMACY.

## Blaud's Pill in "Tabloids."

(Four grains.)

The CHEMIST AND DRUGGIST, Sept. 10th, 1892, reports:—"The ingredients of a four-grain Blaud's Pill are combined in the 'Tabloid' without excipient, providing a cream-coloured mass. The first thing that strikes one about these 'TABLOIDS' IS THEIR SMALL SIZE COMPARED WITH THE USUAL BLAUD'S PILL, but we have found that the average weight is between  $\frac{1}{4}$  and  $\frac{1}{2}$  grains—a commendable degree of accuracy we should say. The colour of the 'Tabloids' is due to the fact that the alkaline carbonate and ferrous sulphate are prevented from reacting until a 'Tabloid' is brought into contact with water, when the characteristic pea-green ferrous carbonate is produced. In air-free water the carbonate is but slightly coloured, showing that the ferrous salt is remarkably free from oxidation. We have also noticed that by gentle friction the carbonate which is first formed comes off, and immediately the white surface below assumes a green colour. Hence it may be expected that assimilation of the iron will proceed steadily, without unduly neutralising the acid contents of the stomach."

The BRITISH AND COLONIAL DRUGGIST says:—"From their form and size these 'Tabloids' can be administered to the most fastidious, and can be taken in any number without the slightest difficulty."

Ferruginous "Tabloids" (Blaud's formula), 4 grains, are supplied to the Medical Profession in bottles of 25 and 100 at 9d. and 1s. 6d. each.

## Soloids of Hydrarg. Perchlorid.

Readily soluble without crushing, are of a different shape to "Tabloids," thus preventing mistake. These Soloids are affirmed to be most convenient for the prompt and accurate preparation of antiseptic solu-

*Specimens sent post free to Medical Men upon request.*

tions for obstetric and surgical work. ONE SOLOID DISSOLVED IN A PINT OF WATER MAKES A SOLUTION STRENGTH 1 IN 1000.

Soloids are as carefully made as "Tabloids," the quantity of the Perchloride being accurately gauged for each Soloid.

Soloids of Hydrarg. Perchlorid. are supplied to the Medical Profession in bottles of 25 and 100 at 9d. and 2s. each.

## Arsenite of Copper "Tabloids"

in

CHOLERAIC AND ENTERIC DIARRHŒA.

Dr. Boardman Reid found this remedy of the greatest value as an *antispasmodic* in CHOLERA MORBUS and COLIC when given in minute doses (one "Tabloid" = 1-1000 grain) every hour until relief is obtained. In all cases where "Tabloids" were employed "relief was rapid and complete." It was observed that when other preparations of the drug were given results were not so satisfactory. The "Tabloids" were perfectly soluble in water; other compressed pellets would not dissolve, thus, it is said, accounting for the failure of the remedy.—(NEW YORK MEDICAL TIMES AND REGISTER, Dec. 6th, 1890, and BRITISH MEDICAL JOURNAL, Jan. 24th, 1891.

Numerous cases of Chronic Diarrhœa and Enteric Diarrhœa successfully treated by this remedy are reported in the THERAPEUTIC GAZETTE, Jan., 1891, and Feb., 1891.

It also afforded prompt relief in the *after pains of labour*, "which entirely resisted all the usual remedies."—BRITISH MEDICAL JOURNAL, Jan. 24th, 1891.

Arsenite of Copper "Tabloids," Triturated, SOLUBLE, supplied in bottles, for dispensing, each containing 100, at 8d. each.

"Tabloids" are dispensed in any quantity by all Chemists with plain manuscript labels.

Physicians are respectfully requested to append the initials "B., W., & Co." after the formula in their prescriptions; this prevents worthless substitutes being dispensed, and indicates to Chemists in out of the way places where the article can be obtained if not already in stock.

**BURROUGHS, WELLCOME, & CO., SNOW HILL BUILDINGS, LONDON, E.C.**

# H. K. LEWIS'S TEXT-BOOKS FOR STUDENTS.

Now Ready, the EIGHTH Edition, in One Volume of over 1000 pages, with Illustrations, large 8vo, 21s.

## THEORY & PRACTICE OF MEDICINE.

By **FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P.,**

Examiner in Medicine at the University of London; Professor of Therapeutics and Clinical Medicine in University College; Physician to University College Hospital, &c.

"The regularity with which fresh editions of this admirable text-book make their appearance serves to show that it continues to maintain its favoured position with the student, who finds it a safe and reliable guide. Apart from the clearness of style and its thoroughly practical character, a great feature of Dr. Roberts' work is the systematic method with which each subject is treated. The value of this kind of instruction is high, as it enables the student to marshal his ideas in an orderly manner, and to assign to each part its special importance. The author has not been unmindful of the necessity of keeping his book 'up to date,' and he has evidently bestowed much pains on its revision. It is enough to say that it fully merits its popularity."—THE LANCET.

"It will be found a trustworthy guide both by students and practitioners, and the latter will find much more information as to treatment than is usually recorded in such works. It is to us a great pleasure to notice an important work from the pen of an old Liverpool man, and we cordially wish it the success which it so richly merits."—LIVERPOOL MEDICO-CHIRURGICAL JOURNAL.

"We have already on more than one occasion expressed a high opinion as to the merits of this work. . . . From our experience of the 'Hand-book,' we believe that it will always be popular amongst medical students, and that it is sufficiently classical to deserve a place on the bookshelves of every physician. . . . We heartily commend it as a reliable guide not less to the practical than to the theoretical study of medicine."—DUBLIN JOURNAL OF MEDICAL SCIENCE.

"We heartily welcome a new edition of this admirable work, which has undergone a thorough revision, and has been, as in previous editions, brought up to the level of our present knowledge. As we have frequently expressed our high estimate of this valuable treatise, we can only once more wish it very cordially the great success which it undoubtedly merits and will certainly obtain."—EDINBURGH MEDICAL JOURNAL.

"Dr. Roberts may fairly be congratulated on having produced the best text-book of medicine we possess."—MEDICAL RECORD.

Now ready, royal 8vo, with 180 Coloured Illustrations, 31s. 6d.

## A TEXT-BOOK OF MORBID HISTOLOGY.

By **ROBERT BOYCE, M.B., M.R.C.S.,**

Assistant Professor of Pathology in University College, London.

"Undoubtedly the most striking feature of the book consists in the illustrations with which it is embellished. These are coloured plates produced from actual photographs; and we can truly say that *we have never met with so complete and perfect a series of micro-photographs as those here given*. There is no lack of clear definition, and each figure tells us, as it should, its own tale. The value of such a collection of faithful reproductions of microscopic preparations must be inestimable to the pathological student. . . . The work is prefaced by an introduction by Professor HORSLEY, with whose opinion we may coincide that the work is one 'which cannot fail to be of much service to the student, whether at home or in the laboratory, and of helpful suggestiveness to the original investigator.'"—THE LANCET.

The TWELFTH Edition, demy 8vo, 16s.

## A HANDBOOK OF THERAPEUTICS.

By **SYDNEY RINGER M.D., F.R.S.,**

Professor of Medicine in University College; Physician to University College Hospital, &c.

"Of Dr. Ringer's well-known 'Handbook of Therapeutics' we can only speak generally in terms of praise. The first edition was not published until 1860, but we have no hesitation in saying that it has practically revolutionised the science of which it treats. . . . Ringer's Therapeutics will always be popular both with practitioners and senior students."—THE LANCET.

"The work supplies a felt want, giving useful information which can be obtained from no other book, and which is of the utmost value in practice. . . . The work has now become almost indispensable both to students of medicine and to practitioners."—PRACTITIONER.

In a few days, FOURTH Edition, Illustrated, post 8vo, 10s. 6d.

## A HANDBOOK OF THE DISEASES OF THE EYE,

AND THEIR TREATMENT.

By **HENRY SWANZY, A.M., M.B., F.R.C.S.I.,**

Examiner in Ophthalmic Surgery in the University of Dublin and in the Royal University of Ireland; Surgeon to the National Eye and Ear Infirmary; and Ophthalmic Surgeon at the Adelaide Hospital, Dublin.

"Well printed, well illustrated, and of moderate compass, it affords just the amount of information that a practitioner who wished to refresh his memory, or a student who is attending a course of lectures and is dressing in the ophthalmic wards of a hospital, requires. . . . We can recommend Dr. Swanzy's book as one of the most intelligibly written and reliable text-books on diseases of the eye amongst the many which have appeared during the last few years, has as yet been written."—THE LANCET.

Now ready, with Illustrations, crown 8vo, 9s.

## MEDICAL ELECTRICITY:

A PRACTICAL HANDBOOK FOR STUDENTS AND PRACTITIONERS.

By **W. E. STEAVENSON, M.D., and H. LEWIS JONES, M.A., M.D., M.R.C.P.,**

Physician in Charge of the Electrical Department in St. Bartholomew's Hospital.

[Lewis's Practical Series.]

"Dr. Lewis Jones has taken the plan of the work which Dr. Steavenson had sketched out and such material as he left behind him, and has incorporated these in a book which is fully up to date, and on its own merits entitled to a cordial welcome. . . . We heartily congratulate Dr. Lewis Jones on having produced an excellent and trustworthy manual."—THE PRACTITIONER.

Now Ready, small 8vo, over 500 pp., 12s. 6d.

## A NEW MEDICAL DICTIONARY.

By **GEORGE M. GOULD, B.A., M.D.,**

Ophthalmic Surgeon to the Philadelphia Hospital.

"More complete and more up to date than any other medical dictionary of similar dimensions in our own, or, indeed, as far as we know, in any other language."—THE LANCET.

"As a handy, concise, accurate, and complete medical dictionary, it decidedly claims a very high place among works of this description. In fact, taking cheapness and handiness into account, we certainly think this the general practitioner's model dictionary, and cordially recommend it to our readers."—BRITISH MEDICAL JOURNAL.

LONDON: H. K. LEWIS, 136, GOWER STREET, W.C.

Inaugural Address,

Delivered on the occasion of the Opening of the Queen's Faculty of Medicine in connection with the Mason College, Birmingham, and the Distribution of Prizes, on Sept. 30th,

By SIR GEORGE MURRAY HUMPHRY,  
M.D. CAMB., F.R.C.S. ENG., F.R.S.,  
PROFESSOR OF SURGERY IN THE UNIVERSITY OF CAMBRIDGE.

THE UNION OF THE COLLEGES, TYPIFYING THE RELATION BETWEEN MEDICINE AND SCIENCE.

GENTLEMEN,—We are met to-day for two chief purposes. First, to celebrate the union—the nuptials, we might say—of two great institutions. The older of these was commenced in 1825 with a course of lectures by Mr. Sands Cox, a well-known figure in surgery in my early time, who had the felicity, as it was also my own privilege, to teach human anatomy in conjunction with physiology and surgery, and to impart to it the interest resulting from that union. It was chartered as “Queen’s College” by Her Majesty in 1845, and has grown into a well-equipped School of Medicine, which is now about to enter upon a fresh, hopeful career in new and extensive buildings, fitted up with due regard to the necessities of modern medical education and supplemented by the clinical material which the hospitals of a great manufacturing centre afford. The other institution has the peculiar interest of being the outcome of the intense appreciation of science by one who from the most humble beginnings and the most humble education had raised himself by practical genius and business quality to be one of the foremost and wealthiest men in this great and active town, and who rejoiced in the hope that he would hereby leave behind him “an intelligent, earnest, industrious and truth-loving and truth-seeking progeny for generations to come.” Could Sir Josiah Mason and Mr. Sands Cox be with us to-day how heartily would they shake hands in the participation of this ceremony, in the realisation of much that they longed for, and in the prospect of much more good results in time to come. The union of medicine and science which is thus typified is one that is essential to the fulness of both and one that has existed throughout their history. The only persons of scientific pretensions in the Homeric period appear to have been physicians. In the great school of Alexandria and in every subsequent great school of learning and science—in Italy, in France, in Germany and in Britain, wherein we still include Ireland, and long hope to do so—medicine has held a prominent place. The physicians—to wit, Linacre and Caius—were the most learned men of their time; and though many still rank high in learning and science the range of literature and the scope of knowledge are now so great that no man can attain the same eminence in many subjects as was reached by those masters in bygone centuries. It thrills me a little when I hear medicine designated as an art. True it is an art; but it is a science also. It is a compound of both; for it is both science and the practical application of science, and the practical application of its science advances *pari passu* with the science itself. Its subject is the human body, in which other sciences, physical, physiological and psychological, culminate, and in the aberrations—the morbid phenomena—of which the most complex and difficult of all scientific problems are found. So difficult are they that they often set scientific thought at defiance and cause charlatanism to step in and cut their Gordian knots. Hence charlatanism has ever been an attendant upon medicine, usurping the field most where science is weakest, and waiting for its expulsion in the time when the further developments of science shall have made deeper search into the mysteries of medicine. Where, it may well be asked, can physics and chemistry find higher and worthier scope than in the anatomical mechanism and in the physiological and pathological processes of man? and how can medicine make much advance except by the aid of these her true handmaids? Never did medicine turn to them with more earnestness and more longingly than at this time, when she is prying closely into the processes of life and searching anxiously into those changes which constitute disease and into the recondite

No. 3605.

sources of them, when a new and fertile field of research has been opened up and patient, careful investigation has given fresh hope of combating the maladies which devastate our people. Sad would it be for both if medicine and science were ever separated, and great reason have we to hope that the aspirations of your founders will be realised by the mutually inspiring work of their institutions; and we may confidently look forward to ever increasingly beneficial results from the proceedings of this day.

It is interesting to note, in connexion with the events of the day, that Sir Thomas Gresban, the prince merchant and great financier of Elizabeth’s time—who appreciated the value of education, having been placed by his father, who was also a great merchant and financier, at Caius College in Cambridge, and who, like Sir Josiah Mason, founded a College of Science which still exists in the city of London—left as an injunction that “the lectures were to teach things interesting to city men, but they must go to the bottom of them.” He thereby indicated his consciousness that interest and benefit lay not simply in the things themselves, but also, and still more, in the mental exercise involved in the search into their causes. Possibly he further indicated his consciousness that that source of interest never could be exhausted, forasmuch as the bottom of things never could be reached, that however deep in future ages the human search might go, a deeper still would remain to stimulate research and to inspire interest. “We speak the wisdom of God in a mystery” are the words of one of the most eloquent and earnest as well as sincere of men. How true is the remark as applied to science, and indeed to all knowledge—*σοφία ἐν μυστηρίῳ*—true now as much as when he wrote, in spite of all the, to us, enormous advance which has taken place in the intervening eighteen centuries and a half; and in spite of our pride of this nineteenth century the source of life and all force is still in what seems to be an eternal, an *Εἰς τὰ αἰώνια*, mystery. The great questions “Whence comest thou?” and “Whither goest thou?” are still unanswered and unanswerable by human ken. They need evidently a higher than human knowledge to tell; and those who are most advanced, and have the highest and clearest range of view, are most ready to admit this.

Our second function on the present occasion is to give honour to whom honour is due, to recognise those who by good work have won their way to the front in student life, and to urge them to continuance in well-doing, and to wish them the future happiness which it will merit.

THE GREEK IDEAL OF EDUCATION APPLICABLE TO MEDICAL EDUCATION.

No nation, I suppose, gave greater heed to education than the Greeks of old, and none with greater success, as is proved by their unrivalled philosophical disputations, their unrivalled dramatic productions, their unrivalled works of art and their unrivalled military prowess. Their ideal was that a man should be a “speaker of words and a doer of deeds,” which implies that he should be also a thinker of thoughts; for good thinking lies at the root of good speaking and good doing. Their aim in education was to make a man eloquent and persuasive in council and brave and resolute on the field of battle, having a good soul and a strong body—as the Romans also expressed it, “*mens sana in corpore sano*”—all the powers developed in due proportion by such mental and physical training as best leads to goodness of soul and strength of body. The consummation of the ideal was that thought should be free and action free by making both rational and so attaining to the realisation of the glorious sentiment “the Truth shall make you free”; and the prize aspired to was the crown of laurel and the respect of fellow citizens. The ideal was a high one, as the ideal of life and duty should ever be. It is an ideal well suited to the life of medicine, for to no man in a greater degree than to the medical man is the combination of goodness of soul and strength of body more requisite; and to no man is the crowning addition of goodness of heart more important. Upon him it devolves to bring hidden things to light, to step cautiously from the old road upon new ways, to weigh probabilities—wherein, I suppose, consists what we call common sense—and with severe bodily strain, by night and by day, promptly and energetically, yet with gentleness and kindness, to carry out the practical application of his knowledge to the relief of his fellow men. Upon no man, in short, is there greater demand for varied qualities of mind and body. To attain them all in any high degree is impossible, but we must not thereby be dispirited, for happily there is no line of life in which good quality of some kind is more appreciated and more telling. Energy and boldness,

quietude and modesty, keenness and inventiveness, patience and perseverance, each and all have influence in the work of acquiring professional knowledge and in gauging and influencing the bodily and mental constitution of the sick.

#### THE WORKING LIFE A HAPPY LIFE.

"Man," it has been said, "is born to trouble as the sparks fly upward." Happily there is a hereditary antidote to this inheritance, for it may be as truly said that man is born to work, and work is one of the great sources of his happiness. The work-a-day life is the happy life. Many of you have already experienced this, and all of you may be congratulated on the prospect of more fully realising it in the working life that is before you. Many of you, I say, have already experienced this, for those of you, at any rate, who have won the laurels know the pleasure of work. Everyone has pleasure in work when he takes to it with earnestness. Pleasure in work is therefore a measure of earnestness in it, and the better the work the greater the pleasure. You gentlemen who have thus far succeeded therefore had pleasure proportionate to your earnestness in the good work you have had to do. All power brings with it its measure of enjoyment, and to man is given, in addition to the animal power and the enjoyment of the body the higher and greater power and enjoyment of mind and thought. The former naturally preponderates in early life, the latter at a later period; but both, as the Greeks felt, are necessary to make up the complement of the perfect man. The young man should rejoice, not only in the growing strength and activity of the body, but also in the increasing vigour and power of his mental faculties and in the means by which both are promoted. Pleasure, therefore, in the time of student life—bodily and mental pleasure—is by all means to be compassed, and I take it for granted that you have experienced and do experience it, and the measure of it enjoyed now is the best guarantee for it in time to come.

#### EXAMINATIONS AND THEIR RELATION TO TEACHING: THEIR DEFECTS.

The examination prospect, I grant, is not always a pleasant one, and the less you look at it the better. The tendency of examinations to cast a gloom over, and to detract from, enjoyment in work is their greatest evil—an evil which much increases with the increased multiplicity of them. It was at its minimum in my day, when a single hour of oral searching was the only trial to which we were subjected at the great portal in Lincoln's-inn-fields, and as the result of it we were sent forth armed, as it was judged, *cap-à-pied*, to combat the maladies which attack the human frame and to wield the scalpel, that weapon more formidable than the sword, upon those who entrusted themselves to us. The threatening cloud, therefore, no larger than a man's hand, cast little shadow upon us. It has now spread over the horizon and almost threatens to deluge the scene and drown the joyousness of study. Well, gentlemen, the only resource is to gird up your loins and run, like the prophet, boldly before it. Examinations are a terror to idle men and should be that only. Keep steadily to your work, and the less you think about examinations the better will you pass them. They should be merely a stimulus and a guide to the diligent, the direction posts along the way telling him what paths he had better take as the best and surest road to the acquisition of that knowledge which will most fit him for the duties he has to perform. It is this feeling which should influence both the examiner and the examinee, both the teacher and the tester of that which is taught. There should be no conflict between examination and teaching. They should coöperate harmoniously in promoting the improvement of mental training and the acquisition of sound knowledge. I do not think this is sufficiently appreciated by teachers, examiners and students at the present time; and I am often surprised to hear the sentiment expressed in an aphorismal and somewhat sententious manner that "teaching should guide examination and not examination guide teaching." It is becoming rather a cant phrase, and I often wonder whether those who utter it have really thought out the purport of what they say. The real fact is that examining and teaching are, and must be, supplementary to one another. The examiners and the teachers are, or should be, guides and checks and adjuncts to one another. They should combine to indicate the best subjects and the best methods. Every teacher is improved as a teacher by examining students other than those he has taught, as well as by examining his own students, and every examiner is improved as an examiner by regarding the students from the

point of view of a teacher. I have for many years been an examiner as well as a teacher, and I do not think I ever learnt more as a teacher than by examining during a period of ten years at the College of Surgeons, where I became intimately familiar with the thoughts and methods of other teachers, realised my own failings and theirs, and appreciated more fully the qualities and the needs of the various classes of students. I would say that for the completion of the mental equipment of a teacher it is desirable that he should have the experience derived from being an examiner of students who have been taught by others. I highly estimate the value, both to the student and to the teacher, of class examinations which I have been in the habit of conducting almost daily for nearly fifty years, and I also highly estimate the value, both to the student and to the teacher, of that wider area of examination in which teachers are confronted with those who are not their pupils, whereby the range of view and thought of both teacher and pupil are widened and over-assurance in individual method and idea is checked. Each question which an examiner puts has—indeed must have—an educational bearing and should be looked upon in that light by him who sets it; and the right-minded student will not regard his examiner from a hostile point as one who is actuated by the exclusive desire to probe the depths of his ignorance. Be it remembered that it is the part of the examiner to ascertain ignorance as well as knowledge, that it is hard to do one without the other, that if the student does not know the position of the femoral artery, or the symptoms of pneumonia, or the treatment of iritis, it is the duty of the examiner to find out such voids and others of more or less serious import.

#### TOO MANY SUBJECTS AND TOO MUCH DETAIL.

The great defect in examination consists, I think, in the difficulty of estimating power in the application of knowledge. It is comparatively easy to ascertain whether there is or is not the knowledge of a fact; but it is by no means equally easy to ascertain whether or not there is the knowledge of the bearings of the fact—that is, its relation to other facts; whether, in short, there is the power of thinking about the facts known, and the power consequently of rendering the knowledge available. This difficulty of holding the balance between knowledge and thought is, and I fear must be, one of the chief defects in examinations, however conducted, and is the cause of some of the dissatisfaction which we hear now and then expressed with regard to the results in particular instances. One can quickly and easily ascertain whether a candidate knows the symptoms of a dislocation of the hip and the method to be employed for its reduction; but it is a longer and less easy process to ascertain whether he understands the *rationale* of the symptoms and of the treatment required.

#### FACTS AND THOUGHTS.

Herein lies the difference between what is called "cram" and intelligent knowledge. The one is just an acquaintance with facts, the other implies an inquiry into and acquaintance with their causes, their beings, use and ends—an acquaintance, that is, with principles. The two should go together. In this matter-of-fact age, when practical knowledge is so much in demand, the one commonly dominates over the other; and the tendency in teachers is to crowd the student's mind with copious, too often ill-digested, facts, and in examiners to estimate the amount held and producible at a given time rather than the ability to use it. This is attributable in no small degree to the number of subjects required, and still more to the increasing details in each; and it is to be corrected only by paying more attention to principles and less to details: in the subjects accessory to medicine—especially biology, physics and chemistry—to give and require a good grounding in principles, with so much detail only as serves to illustrate the principles. The same remark applies to some extent to physiology and *materia medica*. The need of this limitation of detail grows as the several subjects grow, and as the teaching and examining in them fall more into the hands of those who are specially instructed in them and highly estimate them; and whenever I read over syllabuses of study and examination papers I am impressed with the importance of narrowing the range of detail required. This feeling grows with me more and more; and I feel with regard to certain subjects that they had better be left out of the programme altogether than that the student should be overlaid and wearied and his spirit broken by the multitude of facts and details that are required to be got up. The work of pro-

essional study, above all, should be happy work, and the period spent in it should especially be a cheerful, happy period. The work is then most likely to be well done without damage to body or mind and the results well remembered; and there can scarcely be a greater bar to educational progress than that which causes a distaste for study, and which, by overloading, makes work burdensome and painful to bear, and turns into dislike that love of knowledge which is a natural feature, an inborn and most blessed quality of the human mind—that, indeed, to which all progress is mainly due. All facts have a halo of interest about them which gives them their attractive glow, without which they are scarcely worthy of a place in the human thought. Facts may be regarded as pegs whereon thoughts may be hung, and thoughts are the rivets whereby the pegs are fastened. I do not wish you to despise facts. Without them there can be no thoughts, and those who have the clearest knowledge of facts are usually the persons who have the greatest power of thinking and reasoning upon them. This must not be forgotten, for facts constitute the great stronghold of medicine; the marking of them is the basis of experience, and the best and keenest observer of facts, who is usually also the best holder and combiner of them, is the best practitioner of medicine. Hence the cultivation of the good and acute observation of facts is, or should be, one of the great aims in medical education. It is indeed to the combination of the two great qualities, observation and reflection, that man owes his pre-eminence in creation; it is to the amount of good balance of these two that one man owes his superiority over others. By this the great masters in our profession, all along the line of its history, from Hippocrates to those who now hold sway, acquired and hold their places. By this you must hope to win, and remember it is such under your own control.

#### THE IMPORTANCE OF ATTENTION.

Both observation and reflection imply and are much dependent upon attention. It may be called the cardinal talent, without which little can be done, whatever other qualities may be present. The attentive or intent worker is the good worker, whether in a manual or a mental sphere. Slovenliness in either results from want of attention. The attentive man is talented and the talented man is attentive. The cultivation and promotion of this faculty should be the great efforts of education. This indeed is the necessary effect of good education, for no good learning can be done without it. It is the soul of accuracy; it is the soul of memory. If a man cannot remember, you may be certain that he cannot attend. It is the soul of good thought and ripe judgment. Cast your eye round the dissecting room, you soon perceive who are the real learners of anatomy. You judge by their intentness, uninfluenced by slight surrounding abstractions. A glance at the dissections enables you to judge by the neatness or slovenliness—i.e., of the greater or less attention that has been given to the manipulatory process. A few questions tell you whether there is real attention and thought upon the work which is being done, whether the student is a mere manipulator or whether he knows what he is about. A few questions upon the part dissected three or four days ago gives still more valuable information, forasmuch as you then elicit information as to the enduring value of the attention—that is, of the impress which attention has made. A student reads in the ward a case which he has just taken. You judge of his attention to the case by the account he gives of the patient's appearance, tongue, pulse &c., and by his description of the malady, and you form an estimate of his thoughtful attention from the manner in which he infers the nature of the case by the collection of the symptoms. Question him upon the case a few days afterwards without his note-book and you ascertain to what extent his memory was impressed, and you judge that the recollection of the case is proportionate to the attention bestowed in taking and thinking upon it. You learn, in short, what real good the case-taking did him. How far better, as a process of mental training in observation and thought, is one case well—i.e., carefully—seen and taken as compared with many cases carelessly observed, the results in knowledge being proportionate not so much to the opportunities of seeing many cases as to the attention bestowed upon a few. It is not the walking round a hospital that gives large, rather I should say deep, knowledge. The test of this will be afforded by a few questions at the conclusion of the visits, such questioning being, I apprehend, the very best kind of clinical lecture that can be given. Unfortunately, it will be found that the knowledge acquired is often in an inverse ratio to the number of cases which

have been seen. Let a man observe carefully the cases in the Birmingham hospitals, let him note well the questions and remarks of the able and experienced medical officers in examining the patients, for each question has its import, and he will have ample field for the acquisition of medical knowledge. Let the student digest the food thus supplied him and he need have no sighing for pastures new.

#### SELF-EXAMINATION AND INDEPENDENT THOUGHT.

Finally, gentlemen, let me exhort you to cultivate the habit of examining yourselves. At the conclusion of each hospital visit consider what you have seen and learnt and thus impress the lessons on your memory. Hurry not from one thing to another. In this, as in so many other things, the more haste the less speed. At the same time do not dawdle. Be intent, but be deliberate. By questioning yourselves you will be your own best teachers. Rely not so much on others as on yourselves. By cultivating self-reliance in study you will best promote self-reliance in your future vocation. We hear much at the present time of German universities, of German teachers and German students. We acknowledge their superiority in some respects, more especially in the opportunities for, and the devotion to, research, and we would, if our restrictive laws did not hinder, imitate them in this; but we wish you to hold by the freedom and independence of thought and the energy and activity of Englishmen. We would not that you should be dragged at the chariot-wheels of any heroes, for that implies deadness or weakness, but rather that you should stand erect and march on by your own force with the firm, straight, dignified step that indicates strength of mind, determination of purpose and unselfish nobility of character.

### A CASE OF CEREBELLAR ABSCESS, SECONDARY TO EAR DISEASE, TREATED BY TRE- PHINING AND DRAINAGE OF ABSCESS; DEATH.

BY BRIGADE-SURGEON LIEUT.-COL. C. E. HARRISON,  
M.B. LOND., F.R.C.S., ENG.,  
GRENADIER GUARDS.

PRIVATE C. M.—, 4th Dragoon Guards, was admitted to the Guards' Hospital, Rochester-row, on the afternoon of July 22nd, 1892, with the following history. Two years prior to the present illness the patient had been the subject of purulent discharge from the left ear, which is stated to have subsequently ceased until he was laid up with scarlet fever at Aldershot in February last, when it recurred. The present illness commenced during a period of six weeks' furlough, subsequently to the attack of scarlet fever which he was spending at his mother's residence at Fulham. On or about May 29th, two days prior to the expiration of his furlough, he was seized with acute pain in the left ear and head, accompanied by vomiting. There were no marked rigors at this time, but there was some diarrhoea, which, however, did not last long. The mother states that the inability to retain food lasted fourteen days and then ceased, but recurred for three days recently. Medical treatment was obtained and his furlough extended. He improved sufficiently to be able to sit up for a short time a fortnight before the date of his admission, but on the same day a relapse occurred, accompanied by severe headache, chilliness, but no vomiting. He lost flesh rapidly. There had been delirium at times and constipation had been present. On admission his condition was as follows: Body much wasted, abdomen very retracted, skin pale, surface of body and limbs very sensitive to pressure, pupils equal and sluggish, either dilated or moderately contracted. There was no marked paralysis in the limbs, face or ocular muscles. There were and had been no convulsions. He was partly conscious and able to answer questions, but groaning loudly at times as if in severe pain. Speech was not markedly slow or cerebation particularly sluggish. He was inclined to ramble in his talk. The tongue was furred and the breath rather offensive. There was thick, fetid, purulent discharge from the left ear, which was said to have been profuse. A polypus was found to exist, and this was snared

with a wire polypus snare on the night of his admission and the stump subsequently touched with a saturated solution of chromic acid. It was difficult to obtain a satisfactory view of the optic discs; but the vessels of the fundus were seen to be well defined, and the fundus did not appear "woolly." There was no marked tenderness and no redness or œdema over the mastoid process, but he was inclined to complain of tenderness on pressure at any spot, whether on the head, trunk or limbs. Any evidence therefore to be obtained by percussion over the skull was considered to be unreliable. There was no pain or swelling down the left side of the neck. The right ear was healthy and the membrana tympani intact. Temperature, 98.2°; pulse, 56. From the history of the case and the past and present symptoms I formed the opinion that an intra-cranial abscess almost certainly existed; but whether the pus was located in the cerebrum or in the cerebellum the symptoms and physical signs left doubtful. It was hoped that some improvement would result from the removal of the polypus, which probably had obstructed the discharge of pus. It was thought advisable to carefully watch the case, unless any unfavourable symptom occurred, until Monday, July 25th, and, if no improvement had resulted, to trephine over the temporo-sphenoidal lobe and explore for pus. If no pus could be found in this situation it was determined to trephine the occipital bone and explore the cerebellum. On the 23rd he had passed a bad night and had been noisy. There was very little discharge from the ear. Evening temperature 98.4°, which fell at a later hour to 97°. Pulse, 60 in the morning, 56 at night.

On July 24th the morning temperature was 98.4°, falling before midday to 97.7°; pulse 64. In the afternoon his condition had changed for the worse, the pulse having increased in frequency to 122, and the symptoms of coma having also increased. Temperature 97°. It was thought necessary therefore to operate without delay. No anæsthetic was given, as from the condition of his circulation and his blunted sensibilities it was thought inadvisable and unnecessary. He resented the incisions through the skin and muscles, but otherwise did not appear to suffer much pain. Surgeon-Major Magill, Coldstream Guards, kindly assisted me. The measurements used for defining where the trephine should be applied were those laid down by Mr. Barker in his lectures at the Royal College of Surgeons in June, 1889. For reaching the temporo-sphenoidal lobe an incision about an inch long was made vertically, having its centre at a point an inch and a quarter behind the centre of the meatus in Reid's "base line" (passing from the inferior margin of the orbit backwards through the centre of the meatus), and an inch and a quarter above the line. A second short incision was made, passing backwards from the centre of this incision. The soft tissues having been separated from the bone a half-inch trephine was applied having its centre at the point above indicated. The circle of bone was removed and the dura mater incised. A trocar and cannula having the diameter of an ordinary knitting-needle were then passed in various directions into the brain substance. No pus was obtained. Accordingly, a spot was chosen an inch and a half behind the meatus in Reid's "base-line" and one inch below it, with a view to explore the cerebellum. A vertical incision was made, and—the smart hæmorrhage which occurred having been stopped with catch-forceps—the soft tissues were cleared from the bone with an elevator and the handle of the scalpel, and a quarter of an inch trephine applied with its centre at the above-named point. The circle of bone having been removed, the trocar and cannula were introduced into the cerebellum, when some very thick pus slowly flowed out. A larger cannula was introduced, and finally an indiarubber drainage-tube, nearly a quarter of an inch in diameter, which was left *in situ*. About three drachms of pus altogether were evacuated. Some boracic lotion was then injected with the view of washing out the abscess cavity. A rectal injection of milk and brandy had been given before the operation, and towards the close the pulse was so unsatisfactory that repeated hypodermic injections of brandy were given. The pulse improved and he was able to swallow. Silver sutures were used to close the wounds and sal alembroth gauze, moistened with perchloride of mercury lotion, was applied.

On the following morning (July 25th) his aspect was improved; he was more conscious, realised what was said to him and swallowed nourishment (half an ounce of brandy with milk every three hours); pulse varying in frequency from 102 to 110; temperature 97°. In the evening the wounds were dressed; there was no pus in the dressings. The pulse

was much the same as in the morning; temperature 97°. The drainage-tube was taken out, washed, shortened about one-third of an inch and replaced. The ear had been discharging; the pupils were equal, reacting to light, but rather sluggish; at 11 P.M. the pulse was very variable (100 to 116), temperature 97.8°; the respiration was irregular and bore much the character of Cheyne-Stokes respiration; his aspect, however, and his mental and general condition gave reason to hope at this time that improvement would continue. On the morning of July 26th his condition was unsatisfactory; he had vomited, and was evidently failing; hypodermic injections of brandy were given, but he grew gradually weaker and died in the afternoon at 3.15; during the morning his temperature had been 100.4°.

*Neuropsy, twenty-one hours after death.*—The condition of the wounds was satisfactory. The upper wound gave evidence of healing by first intention, and the trephine opening was occupied by lymph and blood-clot; the dura mater lining the left inferior fossa of the occipital bone was a little congested and roughened in places, but with this exception there was no evidence of meningitis; no subdural abscess was found, and no extravasation of pus into the meninges or ventricles; the trephine opening into the left inferior fossa of the occipital bone was found to occupy the most dependent position, thus favouring free drainage. The brain tissue was but little altered in appearance by the wounds made by the trocar and cannula. The abscess cavity in the left lobe of the cerebellum was not circumscribed, the walls of the cavity, except at the inner and anterior portion, where the tissues were somewhat indurated, being formed of softened brain tissue. The drainage-tube freely entered the abscess cavity, which contained a little very thick pus. On examining the petrous portion of the temporal bone the dura mater covering the central part of the anterior surface, and to a less extent the posterior surface, was found discoloured, and on removing this a large piece of necrosed bone not yet loosened from its connexions was observed. There was a small perforation also at the posterior part of the anterior surface of the bone leading into the mastoid antrum, but no evidence of any active inflammatory mischief in the mastoid cells was found. The edges of the mitral and aortic valves were thickened slightly, and on the latter valves were some very minute vegetations just visible to the naked eye. The other organs were found healthy.

*Remarks.*—In this case the antecedent history and the symptoms which the man presented on admission to hospital left little doubt as to the course which should be adopted. The patient's aspect and mental condition, the history of rapid loss of flesh, the subnormal temperature, infrequent pulse and retracted abdomen, taken in conjunction with the existing ear disease which had originated at some date prior to the commencement of his present acute symptoms, all pointed to intra-cranial suppuration. Although the symptoms did not lead one to hope that by freely opening the mastoid cells and scraping out the polypus and the granulation tissue occupying the middle ear relief would be given, yet it may be argued that this should have been done before proceeding to explore the interior of the skull. The patient's condition, however, on the day of the operation had become so grave that it was thought right to trephine at once rather than to prolong the operation by first opening the mastoid antrum. It was felt that this minor operation for effecting the drainage and cleansing of the middle ear might be performed subsequently in the event of the patient's condition improving. It is to be regretted that the cerebellar abscess was not opened forty-eight hours earlier—on the afternoon of the man's admission to the hospital.

**INSTRUCTION IN FEVERS.**—A notice has just been issued by the Metropolitan Asylums Board informing medical students that a course of instruction in the diagnosis and treatment of fevers will be given at the following hospitals, the fee for the course being three guineas for two months, and one guinea for each month afterwards:—Eastern Hospital (Dr. E. W. Goodhall), Tuesdays and Fridays at 10.30 A.M. North-Western Hospital (Dr. W. Gayton), Tuesdays and Thursdays at 11 A.M. Western Hospital (Mr. R. M. Bruce), Tuesdays and Fridays at 11 A.M. At the above hospitals the course will commence on Oct. 4th. The lecturers at the South-Western and South-Eastern Hospitals (Dr. F. F. Caiger and Dr. MacCombie) respectively will commence on Oct. 11th, and will be given on Tuesdays and Fridays at 11 A.M.

## THE TREATMENT OF FILARIA SANGUINIS HOMINIS.

By P. MANSON, M.D., LL.D. ABERD., M.R.C.P. LOND.

My experience of the action of thymol on the filariæ of the blood coincides with that of Surgeon-Lieutenant-Colonel A. Crombie as detailed in THE LANCET of Aug. 13th. Soon after Surgeon-Lieutenant-Colonel E. Lawrie's article on this subject appeared in THE LANCET of Feb. 14th, 1891, I had an opportunity of trying thymol in the case of a negro in whose blood both species of African filariæ—viz., filaria sanguinis hominis diurna (major) and filaria sanguinis hominis perstans (minor)<sup>1</sup>—abounded. This patient took thymol regularly for over two months without any effect whatever on his blood parasites—at all events at the time—and six months later they were quite as abundant and just as active as before treatment commenced. The attempt to cure filarial chyluria by the administration of a parasiticide, as suggested by Surgeon-Lieutenant-Colonel Lawrie, is founded on a misconception of the true pathology of this disease and of the part played by the filaria in its production. The filaria stands to chyluria very much in the same relationship as rheumatic fever stands to heart disease and gonorrhœa to urethral stricture; it starts the disease process, but its constant presence is not necessary for keeping it up. To attempt, therefore, to cure chyluria by trying to kill the filaria is as illogical and as useless a proceeding as to attempt to cure established heart disease by salicylates or stricture of the urethra by astringent injections. This is evident if we consider the order of events in the production of chyluria. This is as follows: A parent filaria is lodged in the thoracic duct. In some way not yet understood it injures the walls of the vessel, causing ulceration or inflammatory thickening. In time this lesion leads to stenosis of the duct. *Pari passu* with the development of the stenosis the thoracic duct on the distal side of the stricture dilates, owing to the rising excentric pressure from accumulating contents. After a time the stricture becomes so narrow that the lymph and chyle no longer find their way past it to the left subclavian vein. They seek, however, to reach the blood by another route; a retrograde movement down the thoracic duct sets in, and so, travelling by way of the pelvic lymphatics, the lymphatics in the walls of the abdomen, and the anastomosis between these and the lymphatics of the upper part of the body, the chyle from the intestines and the lymph from the lower extremities find their way into the circulation. Possibly there are other routes, as by the lymphatics of the œsophagus, diaphragm and back; it is certain, however, that a common course pursued is that described, which is very much the same as that pursued by the blood in the case of obstructed portal circulation. To accommodate this increased and diverted chyle and lymph circulation the lymphatics by which it passes become enlarged and in many places varicose. The tendency to varicosity is very evident in such places as the scrotum, mucous membrane of the bladder, or wherever the lymphatics are abundant and feebly supported. In many instances these varices, where superficial, can be seen or felt and their nature readily recognised. If the inguino-femoral glands are involved the varicose groin glands, so characteristic of filaria infection, are produced; if the scrotal lymphatics are in the track of the regurgitating lymph and chyle the equally characteristic lymph scrotum may be produced. Sometimes the varix is apparent on the surface of the abdomen even, as in the case related by Sir William Roberts and in another by Hævellling<sup>2</sup>: That these varices are really part of an anastomosis conveying chyle from the abdominal viscera to the blood is proved by the nature of their contents; these are usually milky white or slightly red tinted chyle—not lymph, clear and limpid, such as comes from the legs. As the lacteals are the only source of chyle these chylous contents of the varicose lymphatics must have come from that source, and the route followed must have been the retrograde one I describe. Now if the lymphatics of the bladder happen to be involved in the compensatory anastomosis, and if they give way, as the lymphatics of the scrotum so frequently do in similar circumstances, the result is a leakage of chyle into the bladder and chyluria. It is evident

from this that the embryo filariæ, although they are generally present in the blood and urine in chyluria, have nothing whatever to do with its production. This is further proved by the fact that in some few cases of genuine and persistent tropical chyluria no embryo filaria can be found either in blood or urine. I had recently such a case under observation. In such cases the parent filaria must have died after injuring the thoracic duct, or possibly there may have only been a male or an unimpregnated female parasite present. Further, although the parent filaria was necessary for the production of the lesion in the thoracic duct in the first instance, its continued presence there is not necessary for the maintenance of the lesion. So that whether the filaria which originally wrought the mischief dies or lives is a matter of no consequence as affecting the chyluria; the stricture of the duct once produced is permanent, and the chyle will continue to flow along the compensatory anastomosis, and perhaps from time to time burst the walls of the varix and appear in the urine. That this is the pathology of most cases of chyluria is proved by more than one post-mortem examination, as well as by a multitude of observations on the living subject. This being the case, it is difficult to see in what way benefit could accrue from killing either the embryo or the parent filaria, or how an anthelmintic, even supposing it were effective as such, could possibly cure chyluria. Many declare they have cured chyluria by drugs; but those who say so should bear in mind that nearly every case of chyluria ceases spontaneously from time to time and also recurs spontaneously, no matter what treatment is adopted. I have no doubt Surgeon-Lieutenant-Colonel Lawrie's cases recovered while taking thymol, but I do not think they recovered permanently, or in consequence of taking this drug; and so with Dr. Walsh's cases referred to by Surgeon-Lieutenant-Colonel Crombie. A knowledge of the pathology of chyluria, elephantiasis and filaria disease in general teaches us that our endeavours ought to be directed rather to keeping the parasite alive and in a healthy state than to interfering with it and worrying it into conditions of ill-health in which the functions of gestation are imperfectly performed. There is a considerable body of evidence to show that under normal conditions the filaria is innocuous, and that it is only when abnormally located, or when it acts as an irritant, or when from some cause the contents of its uterus are prematurely evacuated, or when it dies, that this parasite becomes a danger to its human host.

I have lately obtained some striking evidence as to the nature of the connexion of filaria nocturna with elephantiasis, and which has an important bearing on this point in the treatment of filariasis. Through the kindness of Surgeon-Major Elcum (Cochin) I received 88 slides of blood drawn during the night from 88 natives of Cochin, a district of India in which elephantiasis is excessively prevalent. Of these 88 Cochinese, 14 had elephantiasis and 74 were healthy. Of the slides from the 74 healthy subjects 20 contained filaria nocturna embryos in abundance. Assuming that these 74 Cochinese fairly represented the general population of Cochin as regards liability to filariasis, we may conclude that about one individual in every 3½ in Cochin is infested with filaria. Of the 14 slides from the 14 cases of elephantiasis only one contained filaria. At first sight this result might seem to be conclusive against the filarial origin of elephantiasis. A little reflection will show, however, that this is far from being the case; that, on the contrary, it is a very strong argument in favour of this doctrine. For why should the subjects of elephantiasis enjoy this apparent comparative immunity from the filaria in a region where it is so extensively prevalent, unless it be that the filaria is in some way connected with the elephantoid condition? The fact is that the immunity is apparent only. Elephantiasis has for its remote and originating cause obstruction of the lymphatic circulation in the part affected. This is universally admitted. I have endeavoured to show<sup>3</sup> elsewhere that the cause of this obstruction in the case of elephantiasis is an embolism of the afferent vessels of the lymphatic glands by prematurely expelled ova from an aborting female filaria. If there is obstruction of this sort in a gland-guarded lymphatic area, such as the lower extremities, then it is simply impossible for filaria embryos to traverse the glands and enter the circulation; the implicated parts are cut off as it were from the blood. Therefore it is that, although the filaria produces elephantiasis, it is a comparatively rare thing to find the filaria in the blood in these cases, as it is impossible for the embryo filariæ proceeding from

<sup>1</sup> THE LANCET, Jan. 8rd, 1891.

<sup>2</sup> Virchow's Archiv, Bd. lxxxix.

<sup>3</sup> The Filaria Sanguinis Hominis, &c.: H. K. Lewis.

the parent in the implicated area to enter the circulation. This shows the importance of protecting the filaria and the danger of injuring it. If in these fourteen Cochinese the filaria had remained healthy, never aborted, never obstructed the lymphatics, there would have been no elephantiasis. And so I hold that once established in the human body the filaria should be left alone, protected rather than persecuted. Pathology indicates that the proper treatment of chyluria is in principle the same as the treatment of acquired varix in any inaccessible region. This should be rest, elevation, lowering of the tension in the lymphatic vessels by the use of saline purgatives, limited and appropriate food, abstinence from fluids as much as possible. Certain drugs have been vaunted as specifics for chyluria; I have tried several of them, but never with success of a permanent character. Temporary recovery from time to time is the rule in chyluria, and the drug which was being used at the time the urine cleared spontaneously from healing of the rupture in the varix in the bladder is often credited with the cure. I cannot understand how a drug introduced by the mouth can possibly cause the closure of a gaping varix in the bladder.

Queen Anne-street, W.

## HIPPOCRATES AND ELBOW FRACTURE.

By A. HANBURY FRERE, M.B. EDIN.

IN view of recent papers, notably those of Nunn before the Clinical Society of London and of Stimson and Lane before the American Surgical Association, I think it may not be out of place to draw attention to what Hippocrates says on this important subject. Reference to Adams's translation for the Sydenham Society will show that Hippocrates did not simply put the arm up at right angles; on the contrary, he gives very explicit instructions, which seem to have been entirely disregarded, and which Adams himself appears to have misunderstood. Hippocrates shows that it is bad to bind the arm in the extended and semiprone (Archer's) position, or the extended and supine position, because when the arm thus bandaged is bent to a right angle the bones at the elbow assume a different attitude from that assumed when they were bound up. He then says: "But if one will extend a broken arm as I direct, he will turn the bone situated at the extremity of the little finger into the straight line and also the one at the elbow, ..... and when the arm is suspended in a sling it will be in the same attitude as that in which it was bound up" &c. Adams in a note says it is the straight position that Hippocrates deprecates. But Hippocrates distinctly tells us to extend the arm and to place the forearm in the only remaining position—viz., in pronation. But what is the difference between flexing a supine or semiprone arm on the one hand and a pronated arm on the other? I am greatly indebted to Sir William Turner, before whom I placed this problem, for having investigated this matter for me, and through his kindness I am enabled to give my own conclusions as facts founded on actual experiment. Morris tells us that "the hand in flexion is carried towards the middle third of the clavicle, and any greater inclination of the forearm towards the median line of the body..... is caused by rotation of the humerus at the shoulder."<sup>1</sup> Associating this fact with what Hippocrates says I came to the following conclusions:—1. On flexing to a right angle a supine or semiprone arm there is rotation of the humerus at the shoulder. 2. On flexing to a right angle a pronated arm there is no rotation of the humerus. In this last the necessary rotation of the humerus takes place on pronating the forearm and while the limb is still in extension. Hence, with the arm bound, extended and prone, it is quite ready to be bent to a right angle without any movement other than flexion. The bones at the elbow may thus be said to be in the same attitude as that in which they were bound up. Now to apply this to elbow fracture, if the fragments be adjusted with the limb extended and supine or semiprone, when the arm is bent to a right angle the necessary rotation of the humerus will tend to occur, not at the shoulder, but at the seat of fracture. Thus, however perfect the setting in the first instance, there is likely to be displacement as soon as we bend to a right

angle. On the other hand, if the fracture be set with the arm extended and prone, there is not the same danger of displacement when bending to a right angle, though, in my opinion, the mere act of flexion may be sufficient to cause displacement. We thus see that there is a very good reason why Hippocrates should say that fracture of the elbow is best set in the extended and prone position. It is only in the straight position of the arm that we can be sure of accurate coaptation of the fragments; however great the displacement it will never be detected so long as the arm is bent. It is not enough simply to put the arm up at right angles and rest satisfied because we have placed the limb in the orthodox position. I do not think this is what Hippocrates meant us to do, and unless we follow the careful instructions he gives us I think the rectangular position is the worst that could be adopted. If I am correct in my interpretation of Hippocrates' words, would it not be better, in all injuries of the elbow, to dress the limb in the straight position with the forearm prone? Those who have employed this method find that they obtain a much earlier return to usefulness and, above all, obviate the deformity so frequently seen after treatment in the rectangular position. With the arm extended and prone the outward configuration of the limb becomes practically straight, so that instead of a complicated angular splint a simple straight one can be applied, thus enabling the surgeon to see that all is right. The normal outward obtuse angle at the elbow is formed by the humerus and ulna; it is still present, therefore, whether the forearm be prone or supine. Whilst, therefore, we are keeping up the normal relation of bone to bone we have a limb that is much more easily dealt with if the forearm be prone than when it is supine, and the latter position becomes extremely tedious after a time. The prone position is a natural one, and most comfortable to the patient; and since it is associated with slight flexion we avoid the danger of over-extension—an important point in treatment of fractured olecranon.

In elbow fracture the injured tissues on the flexor aspect require to be kept at their normal physiological length in order that they may not heal with shortening; the opposite holds good for the extensor surface. The straight position is certainly indicated for injuries of the elbow-joint, more especially as with the arm extended there is no impediment to the flow of the blood or lymph. Absorption can therefore proceed and healing can in this position be greatly aided by means of massage. The most important point in these cases is to obtain accurate coaptation of the fragments. The better the setting the sooner the fragments will unite. The sooner union takes place the sooner will passive motion be permissible. When the joint is first moved I hold that it should be through its natural path. If movement be painful it is very apt to be harmful. Fracture of the elbow is often overlooked; but, if the straight position were to become the rule instead of the exception, then the treatment of dislocation would not be detrimental to possible fracture. Those who use the bent position seem to be the most anxious to begin passive motion early. Those who use the straight position find early motion unnecessary. It is only a question of accurate coaptation of the fragments. In the bent position we can only hope that all is well; we cannot be sure that reduction is being kept up. In the straight position we can be sure of good position, and there will therefore be less tendency to stiffness and an earlier return to usefulness, and, further, less likelihood of exuberant callus; and we entirely avoid deformity.<sup>2</sup>

<sup>2</sup> Those interested in the subject will be glad of the following references:—Provincial Medical Journal, Jan., March, and April, 1892; Transactions of the American Surgical Association, vol. ix., 1891.

THE members of the Metropolitan Asylums Board will inspect the new fever hospital now in course of erection at St. Ann's-road, Stamford-hill, N., to-day, Friday.

NEW RECREATION GROUND FOR ST. ALBANS.—Sir J. Blundell Maple, M.P., has sent a letter to the Corporation of St. Albans in which he gives particulars of the gift which he intimated some time ago he was about to bestow on this town. The hon. gentleman will also erect a lodge and cricket pavilion and bear all expenses connected with the laying out of the grounds, which cover about 24 acres. The isolation hospital, which was lately presented to this corporation at a cost of some £4000, has just been completed.

## NOTES ON SOME CASES OF DIABETES INSIPIDUS WITH MARKED FAMILY AND HEREDITARY TENDENCIES.

By CHARLES H. MOLLRAITH, M.A., M.B., C.M. GLAS,  
LATE HOUSE PHYSICIAN, VICTORIA-PARK HOSPITAL FOR CHEST DISEASES.

I HAVE been induced to place on record the notes of certain cases of diabetes insipidus, thinking that they are of interest. Dr. Vincent Harris, under whose care the cases were in the City of London Hospital for Diseases of the Chest, Victoria-park, has kindly given me permission to send particulars of them for publication.

CASE 1.—The case which came most under observation was that of W. S—, aged fourteen, residing in Essex, who was admitted to the hospital on Jan. 2nd, 1892, with a slight cough and a history of wasting, which had been more marked for the preceding two or three months. About fourteen days previously to his admission he had what was called influenza, following on which he had one or two attacks of epistaxis of some amount. He also suffered for a day or two from considerable restlessness and feverishness at night, with drowsiness during the daytime and frequent dull headaches, localised at the top of the head, accompanied with pain behind the eyes, which were said to have had the appearance of being swollen. Since then he felt excessively weak. Even as a child he was subject to extreme thirst and passed large quantities of watery urine. At times he had an abnormal appetite. He never was a strong boy. From infancy till he was three years of age he had been subject to fits—loss of consciousness and struggling. He had measles and whooping-cough and at nine years of age some rheumatic attacks. There was no history of scarlet fever or chorea, and none of injury in childhood. He had always spoken slowly, and for some time had had a catch in his speech—a hesitancy in utterance akin to but not amounting to stammering. He was pallid, anæmic and listless, and at times drowsy; his forehead was broad and perpendicular, but the head was a fair size; his eyes were large and prominent and the pupils widely dilated; his chest was somewhat rounded in shape. There was no marked hollowing of the supra-clavicular or infra-clavicular fossæ. Expansion was good, and, with the exception of a slight harshness of the breath sounds at the left apex, there were no abnormal physical signs to be made out over the lungs. The area of cardiac dulness was not enlarged. The cardiac sounds were free from murmur, but the second sound was accentuated at the aortic base. The liver and spleen were not enlarged. So far as could be made out the kidneys were not unduly large. The bladder extended up to the umbilicus and after urination to midway between the umbilicus and symphysis pubis. The skin was dry and had to some extent a cutis anserina appearance. His hands and feet got easily cold and sometimes were quite livid. There was no hyperæsthesia or anæsthesia and no abnormal sense of heat and cold. His deep reflexes were normal, but his superficial reflexes were exaggerated, especially those over the abdomen. A tache cérébrale could be easily brought out over the chest and arms. His pupils contracted to light and accommodation only very slowly. His tongue was protruded and withdrawn slowly, and was tremulous when protruded. Movements generally were delayed. The muscular system appeared fairly well developed, but the muscles themselves were flabby. His appetite was good, his tongue was broad and flabby, slightly furred posteriorly. The bowels had a tendency to constipation. His thirst was considerable, and he passed a large quantity (about 200 ounces) of pale watery urine, which had a greenish tinge, no odour, a neutral reaction, a specific gravity of 1001, and contained no albumen or sugar and only a slight trace of inosite. The amount of urea present was about 3 per cent., and averaged from 28 to 30 grammes in the twenty-four hours. His pulse was small, regular and of high tension, and numbered 68 per minute; his temperature was 98.4°, and the respiration, which was fairly deep and easy, numbered 28 per minute. During the three months under observation he was placed on a mixed diet and was allowed as much fluid to drink as he wished. The quantity which he drank was carefully measured and a daily record kept. The quantity of urine passed was also carefully noted. Under treatment his general

condition improved considerably. His thirst became much less, and there was also on the average a falling off in the amount of urine passed. He also gained somewhat in weight. The amount of urea present remained between 0.3 and 0.5 per cent., and occasionally the urine gave the reaction for acetone. The following is a table showing the results of treatment:—

Duration of treatment in days.	Specific gravity.	Quantity of fluids taken in ounces.		Quantity of urine passed in ounces.		Treatment.
		Max.	Min.	Max.	Min.	
4	1001-1002	400	404	224	178	Tonics—tincture of nuxvomica.
10	1001-1004	400	285	306	184	
7	1002-1004	420	200	208	208	Liquid extract of ergot, increasing to 1 dr., three times a day.
6	1001-1004	840	200	320	264	Liquid extract of ergot, 1 dr. four times a day.
15	1002-1003	200	195	208	178	Liquor strychninæ, 3 min., tincture of perchloride of iron 15 min., three times a day.
13	1002-1004	205	105	236	140	Antipyrin, 10 gr. three times a day.
11	1002-1006	140	105	230	184	Antipyrin, 15 gr. three times a day.
10	1002-1006	105	60	206	156	Compound tincture of valerian 1 dr., citrate of iron and ammonia 5 gr., three times a day.

CASE 2.—P. S—, aged nine, younger brother to Case 1, had had extreme thirst from infancy, and had always passed a large amount of watery urine. Beyond measles and whooping-cough he had had no illness. There was no history of injury in infancy and none of infantile convulsions. He had been getting weaker of late. He had no cough or expectoration, and no night sweats, dyspnoea &c. His bowels were fairly regular and his appetite good; thirst was excessive. The tongue was pale and flabby, broad and thinly furred posteriorly. His pulse was 84, small, regular and of somewhat high tension; his temperature was normal and respiration, which numbered 20 per minute, easy and of good depth. The urine was pale and watery, with a greenish tinge; its reaction was faintly acid and had a specific gravity of 1002. It contained no albumen and no sugar, but there was present a trace of inosite and also of acetone acid. The patient was pale, anæmic and listless. His skin was dry and livid, due to venous congestion; the veins were well marked all over the body; his conjunctiva, lips and gums were pale; the pupils were dilated; his fingers were livid, and his feet and hands got easily cold. The chest wall was well covered; it was somewhat barrel-shaped, and there was no depression of the supra-clavicular or infra-clavicular fossæ. The expansion of the chest walls was fair. There were no abnormal physical signs over the lungs. The cardiac apex impulse was small, and was felt half an inch inside the nipple-line in the fifth space. The area of cardiac dulness was not enlarged; the sounds were free from murmur, but the second sound was accentuated both at the apex and at the base, to the right of the sternum. The liver and spleen were not enlarged. The abdominal walls were very flaccid. The bladder reached up to the umbilicus, and after micturition it was still considerably enlarged. The skin of the body and chest was very sensitive; the slightest touch anywhere caused him to shrink, as it caused a tickling sensation. The superficial reflexes were exaggerated, especially the abdominal ones. His muscular system was flabby, but fairly well developed. During the period under observation—viz., twenty-four days—the general condition remained pretty well unaltered, the patient drinking between 240 and 135 ounces of fluid, and passing between 320 and 190 ounces of urine. At the same time there was a slight gain in weight.

CASE 3.—E. S—, aged seventeen; as an infant was always crying till he got something to drink. He had what his mother called "infantile fits" from infancy till he was three years of age; none since. He had had measles, whooping-cough, chicken-pox and diphtheria; otherwise he had always been well, but never strong. There was no history of injury &c. He was always a backward boy, his intellect being slow. He had a low forehead, a flushed face, and a dull heavy expression. His pupils were somewhat dilated, his lips heavy, and the lobules of the ears were large and thick. The skin was dry and coarse. His superficial reflexes were exaggerated, his movements generally delayed; his pupils responded to light

and accommodation, but very slowly. He had no abnormal physical signs over the chest or abdomen; his bladder was somewhat dilated. He passed about 368 ounces of pale watery urine, which had a neutral reaction, a specific gravity of 1005, and contained no albumen or sugar, and but a trace of inosite. The amount of fluid drunk averaged about 265 ounces per twenty-four hours.

*Family history.*—Case 1: W. S—, aged fourteen, affected. Case 2: P. S—, aged nine, affected. Case 3: E. S—, aged seventeen, affected. One sister alive and healthy, not affected; one sister died of diphtheria, not affected. Father's family: Healthy, nothing to note. Mother's family: Mother alive, aged forty-six, slightly affected. Three brothers died of wasting, aged five years, seven months and eleven months: all had excessive thirst and passed a large amount of urine. One sister died of phthisis, aged sixteen, not affected. Two sisters alive; one suffers from heart disease and one from winter cough, not affected. Mother's mother is alive, aged seventy-four, slightly affected. One of her sisters is alive and slightly affected. Two sisters died, one of cancer of the throat and one of phthisis; neither of them affected. One brother died of cancer of the intestine, not affected. One brother is alive and is affected with extreme thirst. Neither of them had any children. Mother's grandmother died of cancer of the stomach. Mother's father died, aged seventy-two, of apoplexy. His father, two brothers and one sister died from paralysis, all over sixty years of age; none of them affected so far as known.

That diabetes insipidus is a condition which is inherited to a remarkable degree has been well shown by the cases which have been recorded by Gee and Weil, especially in the marked case of the latter observer. The present cases are also marked examples of its inheritance and what seems to be a heredity occurring chiefly in the males on the female side of the house. The similarity of the three cases is interesting. In all of them the chief symptoms of excessive thirst and the passing of an unduly large amount of urine had been present from infancy. Never in any case while under observation did the specific gravity of the urine rise higher than 1007. The amount of urine passed was always more or less in excess of the quantity of fluid taken, having been in excess as much as 76 oz. on one occasion in Case 1 and 110 oz. in Case 2. In making these observations the possibility of error was carefully guarded against. The bladder in each case was found to be enlarged, and that the capacity of it was considerable may be inferred from the fact that while in the out-patient room of the hospital Case 1 passed about two pints of urine. The retention of this amount had not caused him any inconvenience. Further, the well-marked nervous symptoms present in these cases are worthy of note. These are well exemplified in the general want of expression which was continually present in the faces of the boys; the dulness of intellect, not amounting to idiocy; thin sluggish movements, and, above all, in the greatly exaggerated superficial reflexes. That nervous symptoms had occurred in two of the cases in infancy is certain. In fact, from the circumstances mentioned, it almost seems as if the origin of the disease in these cases is to be found in some peculiarity of brain condition by which some dulling of the functions of the higher centres by which their restraining power over the lower centres has been to some extent lost or, at any rate, modified.

Children's Hospital, Paddington-green, W.

#### A FEW CASES

### ILLUSTRATING THE PROBABLE DATE OF THE COMMENCEMENT OF THE INFECTIOUS PERIOD OF SMALL-POX.

By FRANK COLCLOUGH, B.A. CANTAB., M.R.C.S. &c., ASSISTANT MEDICAL OFFICER AND ACTING MEDICAL SUPERINTENDENT HOSPITAL SHIPS, LONG REACH.

WHEN taking the histories of the patients lately admitted into the hospital ships, Long Reach, I have been much struck with the opportunities given for the spread of small-pox, without, however, that result occurring. Judging from these few cases, one cannot help thinking that the infectious nature of small-pox, at all events in the early stages, has been much exaggerated. The first case I give must be termed a small-pox curiosity, and I give it solely from its

extraordinary history and not that it has any bearing on the points I wish to bring forward.

CASE 1. Mrs. R—, aged forty-six; vaccinated in infancy (three scars); not revaccinated; initial symptoms, malaise before July 2nd, when she became distinctly worse; eruption, July 5th; admitted to the hospital ships, July 11th; discharged, July 30th.—The patient keeps a small general shop and her husband is a baker. Up to July 11th she was attending to her shop. She states that spots appeared on her face and body on July 5th, but she was obliged to serve in the shop, and therefore had a sofa in the back parlour, getting up and down to serve her customers. During this time she was looked after by her husband and daughter (aged thirty and sixteen respectively), and as she quaintly said, "lots of her neighbours would come in and argue whether she had small-pox or not," because a neighbour who had suffered from small-pox in former years declared that Mrs. R— had it then. The husband and daughter had both been vaccinated in infancy, but were not revaccinated on Mrs. R—'s removal, having some strong objections to that process. With all these possibilities no further cases have resulted from six days' exposure in a very wholesale way of a patient with a small-pox eruption. A letter from Mrs. R— after her discharge stated that her husband and daughter had not suffered in the slightest degree and that no spots had appeared on them. It seems hopeless to attempt to explain this, especially as it was definitely stated that the husband and daughter had never had small-pox as far as they knew.

CASE 2. W. J—, a male aged nineteen; vaccinated in infancy (four scars); not revaccinated; initial symptoms, malaise, July 4th, continuing up to July 8th, when he really felt ill and first noticed a rash; eruption, July 11th (about noon); admitted to the hospital ship, July 12th; discharged, Aug. 13th.—The patient is a porter and works at a milliner's, employing twenty-five hands. On July 8th he had been carrying parcels as usual and had had his meals with the rest of the employés. In the evening he went home to bed feeling really ill, where he remained until the morning of July 11th, when he walked to one of the general hospitals in London—about ten minutes' walk. He remained for about an hour in the surgery, which was rather full, until he was admitted into a general ward, from which he was soon removed to an isolation ward. The medical officer in charge has very kindly answered my inquiries, and stated that "no rash was visible, face flushed and temperature 103° 6." About noon that day the eruption appeared, "very small papules on the forehead and a few scattered on trunk," and the patient was removed about 11.30 on the next day, July 12th. Everyone who came into contact with the patient was revaccinated. On admission to the ship this patient had a distinct initial scarlatiniform rash, best marked over the gluteal region, at 9.30, and on the morning of July 13th it was still present over the front of the thighs.

CASE 3. G. S—, a male aged twenty-seven; vaccinated in infancy (stated); scars obscured by eruption; not revaccinated; initial symptoms, July 17th; eruption, July 18th; admitted to the hospital ship, July 20th; death, July 28th.—The patient was employed at a large miller's, having over a hundred hands. On July 16th he went down to Hastings with all the rest of the hands for a beanfeast, and on the 18th he was at work all day in his shop with about sixty men, the eruption having been noticed on his face about 9 A.M. He left in the evening, feeling very ill, to go to the house where he lodged, and in which there were seven other inmates. This patient was well known as a very hard drinker.

CASE 4. C. B—, a male aged thirty; vaccinated in infancy (four scars); not revaccinated; initial symptoms, July 16th; eruption, July 18th; admitted to the hospital ship, July 19th; discharged, Sept. 3rd.—The patient is a telegraph labourer at some works where about two thousand men are employed, and in his shop there are, roughly estimated, fifty men. He was at work up to 3 o'clock on Saturday afternoon, July 16th; he then went straight home to bed and remained there until his removal to the ship. His wife slept with him up to the time of removal (10.30 A.M. on July 19th), and his child, two years old, had a bed in the same room. A medical man saw the patient on the morning of the 18th, when there was no eruption; in the afternoon, about 5 o'clock, it appeared. His wife was in constant attendance and slept with him during the first seventeen hours of the eruption; she was vaccinated in infancy and so was the child, and the wife was successfully revaccinated on July 21st, and has had no signs of small-pox since.

CASE 5. *E. B.*—, a female aged sixteen; initial symptoms, July 21st; eruption, July 23rd (morning); admitted to the hospital ship, July 26th; discharged, Sept. 3rd.—This patient lives with her aunt, who keeps a general store; she does the house work and occasionally serves in the shop. Her sister, aged eighteen, who was home for a week's holiday from Saturday, July 16th, in the evening, to the morning of Sunday, July 24th, and slept in the same room, but not in the same bed, noticed spots on *E. B.*'s arms and hand about 8 A.M. on July 23rd. A neighbour from next door was shown the spots at 11 A.M. and again on the Monday, July 25th, at about the same hour, and the patient was nursed by her aunt until her removal on the 26th, about 6 P.M. The aunt was therefore exposed for three days and a half, the sister for twenty-four hours; to the eruption, and a neighbour for a short time on the first and third days of the eruption. Inquiries elicited the following facts: The aunt, aged thirty-two, was vaccinated in infancy; revaccinated unsuccessfully after patient's removal. Mrs. H.—, the neighbour, aged thirty-four, was vaccinated in infancy; neither had had small-pox. The sister, aged eighteen, was vaccinated for the first time on July 28th, which succeeded; therefore this unvaccinated sister was exposed for twenty-four hours to the eruption without contracting the malady, and since she was successfully vaccinated two days afterwards it is fair to suppose that she was susceptible to variola.

CASE 6. *M. P.*—, a female aged seventeen; vaccinated in infancy (five imperfectly defined scars); not revaccinated; initial symptoms, July 21st and before; eruption, July 24th (about 7 a.m.), face; admitted to the hospital ship, July 25th; discharged, Aug. 27th.—On July 18th she felt sick and had pains all over her; these continued and became worse until July 23rd, when she was not able to do her work. On Sunday, July 24th, she noticed spots on her face and hands when she woke up about 7 A.M. She was nursed by her father until her removal about 11.30 A.M. on the 25th, and was seen by a neighbour for about half an hour on that morning, when she was prepared for removal. The father therefore was exposed to the eruption for about twenty-seven hours and the neighbour for about half an hour on the second day. A letter from the patient's father after her discharge stated that the father was vaccinated in infancy; revaccinated some seven or eight years ago (three vaccination marks); never had small-pox. The neighbour, Mrs. L.—, was vaccinated in infancy; not revaccinated (three vaccination marks); never had small-pox.

CASE 7. *R. B.*—, a boy aged sixteen, on board a training ship; vaccinated in infancy (four scars); stated to have been revaccinated three times unsuccessfully; initial symptoms, June 5th; eruption, June 8th; admitted to the hospital ship, June 8th; discharged, July 15th.—This patient came into the sick bay on June 4th with a temperature of 99°, complaining of malaise. On the next day his temperature was 105.2°, and the eruption appeared on June 8th. The sick bay officer and six boys were in contact with the patient. The officer had had small-pox when young and three of the boys were at once revaccinated, the other three having been revaccinated in 1890. The captain of the ship kindly gave me full details and stated that thorough disinfection was at once carried out and the boy was brought to the ship as soon as the diagnosis was made. Here was full opportunity for the spread of small-pox if the disease were infectious in the incubation period; and six boys were in the sick bay with the patient during the initial illness and the first few hours of the eruption. This patient had confluent small-pox and was a good instance of Dr. Birdwood's theory of small-pox, for the captain stated that the patient had not left the gates of the ship's enclosure, but had been employed as boat boy. The eruption was extremely abundant except over the space covered by his flannel naval vest, where there was practically none; and, strange to say, the line commenced just above the gluteal region behind, as if the shirt had "rucked up" and so not protected the flanks. In front the pocks commenced just below Poupart's ligament. The pocks had sharp lines of demarcation at the shoulders, neck, gluteal region behind and Poupart's ligament in front; and with the exception of this "cuirass" of white skin he was simply one mass of pigmentation on his discharge.

CASE 8. *P. S.*—, a female aged twenty-five; vaccinated in infancy; not revaccinated (three scars, area 52 square inches); initial symptoms, July 24th; eruption, July 28th (early morning), arms then face; admitted to the South-Eastern Fever Hospital, July 30th; hospital ship, July 31st; discharged, Sept. 10th.—This patient was delivered, normal time, on

Wednesday, July 27th, at 10 P.M., by a midwife, who came at 9.30 and left about 11 P.M. Spots were first noticed about 7 A.M. on Thursday, the 28th. The midwife came again on Friday, the 29th, about 1.30 P.M., but fearing some infectious disease would only see the patient from the door for a few minutes. A medical man was then sent for, and the infant was removed soon after his arrival; it had been suckled up to that time, but had not taken the breast well. Mrs. S.—'s aunt helped the patient in her confinement and nursed her up to the time of her removal; the husband was constantly present, and patient's sister saw her for a few minutes on Friday afternoon (29th) when taking away the infant. The midwife was really only in contact with the patient for an hour or so, about nine hours before the eruption appeared, the sister for a few minutes on the second day of the eruption, whilst the husband and aunt were exposed to infection up to the time of removal. I forgot to ascertain the time of removal, but it was late on Saturday, July 30th, for the medical man only diagnosed small-pox about 1.30 that afternoon. The husband and aunt were therefore in contact with the eruption for about two days and a half.

Inquiries elicited these statements from the husband:—Mr. S.—, aged twenty-five; vaccinated in infancy; revaccinated in 1877; five vaccination marks. The sister, aged thirty; vaccinated in infancy; not revaccinated; two large marks. The infant "never had a spot;" was vaccinated when ten days old successfully in three places; died when four weeks old of, according to the father, "nervous debility and inflammation." He could give me no information about the aunt and the midwife. The probable cause of Mrs. S.—'s infection is very interesting. Her two children were sent to the ships through an error of diagnosis, having really chicken-pox on June 16th.

The notes are these: *M. S.*—, a female aged one year and a half; no initial symptoms; eruption, June 15th; admitted, June 16th; vaccinated in infancy (three scars); revaccinated, June 16th and 22nd, unsuccessfully. Condition on admission: Discrete eruption, papular, vesicular and scabbing in different places, some typical varicella vesicles; no pocks on palms, soles and palate.—June 27th (i.e., eleven days after admission): Some papules on face and a few on arms; not shotty, very little raised. Temperature normal; child peevish; no initial symptoms.

*T. S.*—, aged three months; initial symptoms, June 14th, first observed; eruption, June 15th; admission, June 16th; vaccinated in infancy; revaccinated, June 16th and 22nd, unsuccessfully.—July 6th: Drowsy during the afternoon; 10 P.M. crying out; limbs occasionally twitching; headache, flushed. Temperature 105° at 9.30 P.M.—July 7th: Punctate rose rash on legs; three small papules on face, apparently new.—July 8th: Temperature 98.2°. Child seems perfectly well. Patient discharged.

There were many opinions as regards the condition on the 7th, but no definite conclusion. Mrs. S.—'s eruption appeared on July 28th. Dating back fourteen days, makes the probable day of infection July 14th, or six days after the return of her children. Then comes the question as to source of infection: (a) Another strange source. (b) Did the child *J. S.*— have small-pox, modified to an abortive papular stage, which was capable of infecting his mother rather severely on the seventh day after the eruption? (c) The children's clothes. But the precautions taken on discharge are most stringent, and I consider this source unlikely.

CASE 9. *E. C.*—, a female aged seventeen; vaccinated in infancy (four scars); not revaccinated; worked at a dressmaker's in the West-end; initial symptoms, Aug. 13th, about 11 a.m.; eruption, Aug. 16th (morning), face; admitted, Aug. 19th.—On Saturday, Aug. 13th, the usual initial illness commenced about 11 A.M. The patient continued working at her shop until 2 P.M., when she went home to dinner, and then thought a walk would do her good, but before she had gone far she "felt unable to stand up," so returned home and went to bed. On Monday, Aug. 15th, she was seen by a medical man. Spots appeared early on Tuesday morning, Aug. 16th; on the 18th the condition was diagnosed, and the patient was removed about 10 A.M. to the South-Eastern Fever Hospital on the 19th. She was nursed by her mother during the day, by her father (who had had small-pox when young) during the night and the landlady continually saw the patient each day. On the Saturday, Aug. 13th, in addition to eleven other workers at the shop, she was seen by three cousins. On Sunday, Aug. 14th, her sister and two brothers were constantly with her. Her father and elder

brother both work at a large printing establishment, while the younger brother goes to a Board School; her sister works at the same dressmaker's, but in consequence of "slack work" has not been employed since the beginning of August. A letter from the patient's father, in answer to my inquiries, confirmed the above statements, and also added that he himself and the landlady had suffered from small-pox in former years, but that the mother, aged forty-five, who was vaccinated in infancy and successfully revaccinated about twenty years ago, had not had small-pox. The mother therefore was exposed to the infection from the eruption for over three days. I should like to draw particular attention to what might have occurred had small-pox been very infectious during this time.

(a) The patient worked at a large dressmaker's with eleven others up to the first day of initial illness, and was also (b) seen by two cousins on the first day of initial illness; (c) she was seen by a sister and two brothers (employments stated above); (d) there were no less than twelve people living in the same house, in addition to the patient.

CASE 10. J. B.—, a female aged thirty-seven; a case of confluent small-pox, who for some three days was in a most serious condition; vaccinated in infancy (four scars); not revaccinated; initial symptoms, Aug. 12th, 2 p.m.; eruption, Aug. 14th, 4 p.m., face and hands; admitted Aug. 15th.—The patient was last working at her business, at a West-end tailor's shop employing twenty-five hands, on Friday, Aug. 12th. On Saturday, Aug. 13th, she went by omnibus to Charing-cross and then by steamer to Wapping to see her daughter off to the north, returned by steamer to Charing-cross and walked home. Two of her children had lately had chicken-pox (?), but no medical man was called in. This daughter above referred to was supposed to be recovering from that disease. However, on arriving at her destination, news of her coming having been sent to London, she was taken into the local hospital as a small-pox convalescent. The patient, feeling extremely ill on Sunday, Aug. 14th, asked another lodger to come and nurse her, and was attended by this neighbour until her removal, about 7 P.M. on the Monday, Aug. 15th; this woman was therefore exposed to the eruption for about twenty-seven hours. The mother and two daughters had been sleeping in the same bed for many weeks, and one daughter and a son were admitted with their mother, no doubt infected from the others, who had had chicken-pox (?).

From these few cases it is impossible to make a generalisation, but I should like to bring forward in a tentative way the probability that small-pox is not infectious, given ordinary conditions, until the second or third day of the eruption. The only evidence I can give is negative evidence, poor at the best; but the actual incubation period is difficult to determine, especially during an epidemic. Curschmann, for instance, was only able to definitely determine that point in 10 out of 1034 cases. There are so many causes of protection from small-pox which must be eliminated before any definite statement can be made.

1. The personal idiosyncrasy—i.e., insusceptibility to small-pox contagion. This, although there hardly seems any doubt about its truth, is so rare that for practical purposes it may be neglected.

2. The protection afforded by a former attack of small-pox.

3. The protection afforded by a modified attack of small-pox, so slight that often among the poor no medical man is called in. It is quite unrecognised and taken to be chicken-pox or measles, or some sort of low fever with spots, and the diagnosis is only clinched when other members of the same family develop small-pox in its severe type.

4. The protection from recent vaccination successfully performed. (During Dr. Birdwood's time as medical superintendent of these ships over 700 people have been employed as members of the staff—namely, from June 10th, 1884, to Aug. 27th, 1892; and among these there have been only three definite cases of small-pox.)

5. The protection afforded by partially successful revaccination—i.e., vaccination not producing typical Jennerian vesicles, but reaching a papular stage and then aborting. Of this I have myself seen a fair number of instances, but for how long this protection would last the data I have are insufficient for me to give any opinion. As a general rule vaccination may be regarded as absolutely protective for two years. Among our report books there are exceptions. Up to seven years there is a certain amount of protection, and without doubt a great modifying influence; after that period the protective power is rapidly lost, but the modifying influence causing the attack to be much less severe

is retained in many cases. I have seen during the past few months cases which have only been vaccinated in infancy modify most distinctly, although their ages have been respectively nineteen, thirty-one, twelve, forty-six, forty, thirty, seventeen, seventeen, twenty-five, fourteen, and six. Whether these effects have been due to our present line of treatment or to vaccination I cannot say, but I feel rather inclined to give the vaccination the greater credit.

6. As to exposure, if Dr. Birdwood's theory of small-pox, published in the Guy's Hospital Reports for this year, be true, personal cleanliness should be a great means of warding off a possible attack of small-pox after exposure to infection.

7. That prompt vaccination after exposure is not absolutely protective is shown by twenty-two cases which I have tabulated from the report books at the ships since 1886 of concurrent vaccinia and variola, where the revaccinations varied from the day after exposure to the day of the eruption.

Taking the stages of small-pox separately and arguing from these nine cases, I have arrived at the following conclusions:—

1. During the incubation period six of these patients have definitely come into contact, more or less close, with at least a total of 261 individuals—that is, counting the training ship as having 50 boys, which is well within the mark. W. J.— came in contact with 25 persons; G. S.— with 100 at least, more or less intimately, when going to Hastings for his breakfast, and with 60 (roughly) in his shop when at work; C. B.— with 50 when at work in his shop; R. B.— with, say, 50 boys at the training ship; E. C.— with 11 when at her work; J. B.— with 25 when at her work. As no cases, to my knowledge, have resulted from these six patients, I think one may fairly claim small-pox to be not infectious under the ordinary conditions of life during the incubation period.

2. As regards the infectiousness of small-pox during the initial illness the histories given by W. J.— and G. B.— are very definite, and I have been fortunate enough to be able to confirm their statements from other sources.

3. With reference to the infective nature of the eruption, I have given statements of exposure in the case of—(a) G. S.— to about 60 men on the first day, say for eight hours; (b) C. B.—'s wife for seventeen hours, revaccinated three days after the appearance of C. B.—'s eruption; (c) E. B.—'s sister for twenty-four hours, vaccinated for the first time five days after the appearance of E. B.—'s eruption; (d) M. P.—'s father for twenty-seven hours, not revaccinated; (e) J. B.—'s neighbour, exposed to eruption for twenty-seven hours, has moved, no reply to inquiries, and patient was quite a stranger to her; (f) P. S.—'s aunt and husband for two days and a half (see *supra*); (g) E. C.—'s mother for over three days, not revaccinated; (h) E. B.—'s aunt for three days and a half, revaccinated unsuccessfully; and there have been no cases from these respective sources of infection.

Taking positive evidence instead of negative, I find in the report books for 1890 the following cases: A. N.—, a sanitary inspector, and J. C.—, the coachman, went to a patient, H. N.—'s house, to remove him to the wharf on March 13th, 1890 (his eruption having appeared March 9th). They both helped him down the stairs, and, I believe, carried him to the vehicle. On March 26th they both developed the small-pox eruption, and were therefore infected on the fourth day of H. N.—'s eruption, giving an undoubted incubation period of thirteen days to the appearance of the eruption.

T. C.— visited P. M.—, a patient, at his house on May 18th, his eruption having appeared on May 17th. C. M.—, his sister, also visited the patient on May 19th. They both developed the small-pox eruption on June 1st and 2nd respectively, having been therefore infected on the second and third days of P. M.—'s eruption, giving an incubation period of fourteen days to the eruption.

In 1891 there is this case. W. J.—, a potman, served W. D.—, a dock labourer, on March 16th his eruption having appeared March 14th. W. D.— had been drinking in the public-house all the morning, and becoming objectionable several attempts were made to actually turn him out, and there were several scuffles; so W. J.—'s exposure was more than seems to be meant by the word "served," and I believe the potman was the first to suspect what was the matter with W. D.— besides alcoholism. W. J.— developed the small-pox eruption on April 1st, therefore giving the incubation period at sixteen days and infection on the second day.

In these cases there is one weak point. I can find nothing

beyond the bare statements. No times are mentioned; so it is impossible to give roughly the probable infectious period in hours after the first appearance.

As positive evidence of the proposition I am bringing forward there is the following:—

J. S—, a male aged seven, was admitted to the hospital ship on May 11th; eruption, May 9th. He was nursed by his father, who visited him when in a dangerous condition on May 16th, and developed the eruption on May 29th, dying principally through hæmophilia on June 8th. This case strongly suggests the probability that the son was not in an infectious condition when he was removed, but that the father contracted small-pox at his visit to the ships, where revaccination was not performed.

The small-pox epidemic of 275 cases originated in January at a Swiss restaurant near Oxford-street, and is a good example of the value of isolation as carried out by the hospital ships. It is now practically over, there being at present only four patients, and a month has elapsed since the last admission. Judging from the small number of cases which I have had the opportunity of seeing, and from the information of the probable period of infectiousness which I consider I have obtained, I am convinced that early recognition and prompt isolation are the most important steps to take in stamping out small-pox, and that all persons exposed to infection should at once be revaccinated, unless that had been successfully performed within two years. Should the theory which I have, however tentatively, tried to put forward prove to be true in the future, then small-pox, providing proper precautions be taken, ought never to be dreaded by a community, and should become a comparatively rare disease.

My thanks are due to Dr. Birdwood for his courtesy and kindness in permitting me to use the reports of his cases, and for his assistance in giving me the details of the cases showing the incubation periods.

## IPECACUANHA IN DYSENTERY.

By ARTHUR H. HART, M.S., M.B. DURH., L.R.C.P. &c.,  
ACTING PHYSICIAN TO THE FRENCH HOSPITAL, SUEZ.

THE following interesting case, illustrating the magical effect of ipecacuanha in large doses in the treatment of dysentery, has lately been brought under my notice whilst acting as physician to the French Hospital, Suez.

M. S—, a native of Austria, has resided for the last nine years at Ismailia. This town is notorious for malarial fever, and for three months in each year—July, August and September—she has suffered from intermittent fever. The paroxysms of fever came on about 11 A.M., terminating about 3 P.M. Towards the latter part of July of the present year she had a very severe attack of fever accompanied by acute dysentery. The diarrhoea was very troublesome, the bowels being moved as many as fifteen times in the course of the day, and the action being accompanied by much tenesmus. The character of the stools was typical of dysentery—at first yellow, then mucoid and slimy, with a very offensive odour. At the commencement of the attack retention of urine occurred for three days, and there have been subsequent attacks of dysuria. Four days after the commencement of the fever severe pain was felt in the right side, causing difficulty of breathing and accompanied by vomiting of a bilious character. On Thursday morning, Aug. 12th, I first saw M. S— in the consulting-room of the Suez Hospital. She had just arrived from Ismailia with her husband, and was supposed to be in an almost dying condition. On admission her condition was as follows: State of great prostration, with intense irritability and restlessness. Temperature 38°; abdominal tympanites and tenderness; hepatic fulness and intense sensitiveness, dysuria and diarrhoea. The stools were said by the nurse to be of the usual slimy dysenteric character, with a very offensive odour. The patient was placed in a cool ward by herself and absolute quiet enjoined. Twenty minims of tincture of opium were at once administered in a little water, followed in half an hour by half a drachm of ipecacuanha powder. Turpentine stupes were applied to the abdomen and the opium enema of the B.P. given. In the afternoon half a gramme of quinine was given in a cachet. The treatment was so immediately successful in stopping diarrhoea and easing pain that at night fifteen minims of laudanum, followed by a gramme of ipec-

uanha, was again given, with another opium enema. For the first day the patient was allowed nothing but hot milk to drink. Aug. 12th: Patient has had four stools in the twenty-four hours, the temperature being 38.6°C. The ipecacuanha caused a good deal of vomiting, but almost stopped diarrhoea, greatly easing the pain in the side. The following powder was prescribed: Two grains of salicylate of bismuth, one grain of sulphate of quinine, one grain of naphthol, one-third of a grain of opium powder. This powder was divided into four cachets, one being taken every three hours. The opium enemata and turpentine stupes were continued. Milk and soda-water, or barley-water, was all that was allowed for diet.—13th: Temperature 38°C. The patient was very comfortable; slept well. Bowels moved three times in twenty-four hours. No abdominal pain. Allowed milk, bread and bouillon. Medicine to be repeated.—14th: Temperature 38°C. One motion in twenty-four hours.—15th: Temperature 37.8°C., the patient passing natural stools. Gets up during afternoon and takes more solid food. Ordered a gramme of quinine and carbonate of ammonia instead of the bismuth preparation.—16th: Temperature 38°C. The patient progressed satisfactorily.—17th: A slight return of diarrhoea, which was effectually stopped by ten grains of Dover's powder.—18th: All unfavourable signs having passed away, at her own request the patient left for her native home in Austria, with the remark that she would have died had she stayed in Ismailia.

The specific action of ipecacuanha in dysentery is due to its dual *modus operandi* on the intestines, as (a) muscular sedative, and (b) secretory stimulant. The most characteristic symptom of dysentery is tenesmus (Dr. Woodward). There is such exaggerated peristaltic contraction of the rectum and lower portion of the colon that the patient goes to stool from thirty to two hundred times in the course of the twenty-four hours, or sits there for half an hour at a time, straining violently, but passing little or nothing (Dr. Hilton Fagge). The patient is under the delusion that he will pass something that will do him good. The fault does not lie in the irritant to be expelled, but in the irritability of the intestinal muscles. According to Heubner the average quantity of evacuation passed by each patient was found to be only from twenty-eight ounces to forty-two ounces. The great difficulty we have to deal with, then, in dysentery is exalted peristalsis. Ipecacuanha meets the difficulty by acting as an intestinal muscular sedative. A large dose of ipecacuanha stops tenesmus quite suddenly and smaller subsequent doses prevent its return. With a return of the muscular coat to its normal condition the other coats lose their irritability and the accompanying inflammation coincidentally subsides. The mucous membrane is then in a suitable condition for the second action of ipecacuanha to come into play—namely, secretory stimulation. We have now to deal with an enteritis, and here ipecacuanha acts in the same way as in bronchitis. Stimulation of the mucous membrane with secretion of mucus is effected by direct action on the peripheral endings of the gland nerves or minute ganglia (Dr. Whitla). Ipecacuanha has the same beneficial effect in dysentery therefore as it has in bronchitis. The action of ipecacuanha on the liver is that of a powerful stimulant. In dysentery the hepatic functions are in abeyance and bile is absent from the stools. Ipecacuanha directly stimulates the hepatic cells, so that very shortly after its exhibition the colourless slimy stools become feculent. In the words of Dr. Ewart, "Ipecacuanha is a non-spoliative antiphlogistic, a certain cholagogue and unirritating purgative, a powerful sudorific and a harmless sedative to the heart and muscular fibres of the intestines." According to this lucid and comprehensive description ipecacuanha is a perfect remedy for dysentery. In a certain proportion of cases ipecacuanha undoubtedly fails. Dr. Maclean says: "Where it fails it is because it has been given too late, when structural changes incompatible with life have taken place in the affected intestine, or from structural diseases of the spleen, liver and kidneys, or the combined ravages of the malarial and scorbutic cachexias." In those cases where ipecacuanha fails when success ought apparently to attend its administration the fault probably is to be found in the diet. For three hours after the first dose of ipecacuanha only a little ice should be sucked and after that a little iced soda-water and milk. Beef-tea or bread, or very light foods, are fatal to the successful administration of ipecacuanha; and to this cause a great many of the failures of ipecacuanha are doubtless to be attributed. On the second day the ipecacuanha can be reduced in quantity and supplemented by salicylate of bismuth, quinine, naphthol and opium.

Milk should still form the staple article of diet. Later on farinaceous foods and soups may be carefully given, but a return to solid meat should be deferred as long as possible. Mr. Chowdhovry<sup>1</sup> remarks "that the large doses of ipecacuanha, which have been found to be of great use in treating the dysentery of India, are often inadmissible by reason of the nausea thereby invoked preventing the patient from taking a sufficient amount of nourishment." Considering that the success of the treatment by large doses of ipecacuanha depends upon the condition of the patient in not taking any nourishment during the period of its administration, the failure in Mr. Chowdhovry's cases was evidently due to the fact that his patients were trying to take a "sufficient amount of nourishment," thereby actually causing nausea and preventing a cure. There are cases where ipecacuanha fails when administered by the mouth which may be very successfully dealt with by ipecacuanha and opium enemata.

## REMARKS ON

GONORRHOEAL SEPTICÆMIA, OR SO-CALLED GONORRHOEAL RHEUMATISM: SUGGESTED BY A CASE ACCOMPANIED BY HYPERPYREXIA WHICH PROVED FATAL.

By B. A. RUGG, L.R.C.P. LOND., M.R.C.S.

THE case upon which these remarks are founded seems worthy of being placed on record, not only on account of the extreme rarity of a fatal issue in a somewhat uncommon complication of gonorrhœa, but also as going to show the real nature of the affection to be septicæmia, depending on an absorption of the virus into the system, in the same way that puerperal septicæmia depends on a similar absorption from the uterus after delivery. There appears to have been great difference of opinion as to the exact nature of the disease. One thing, however, would seem to be quite clear, and that is that it has no connexion with ordinary rheumatic affections. It is true that it principally affects the joints, but is it not possible that the gonococci may have an elective affinity for the neighbourhood of joints in the same way that the germs of typhoid fever and cholera have a similar affinity for the intestines? The late Dr. Hilton Fagge styles the disease "gonorrhœal synovitis," and states that the pyrexia is almost always moderate, and in some instances the temperature remains normal, and that hyperpyrexia is unknown. Of the 126 cases collected by him recovery seems to have occurred in all, though convalescence was often very tedious and protracted. As regards the pathology, he says that it is quite unknown, but suggests that it may be in some way connected with the abundant nervous distribution over the prostatic part of the urethra. However, in view of this fatal case that does not appear to be at all a probable explanation. Yet he mentions on the authority of Petrone and Kammerer, quoted by Eichhorst, that the micrococcus of gonorrhœa has been found in the effused serum of the knees. Mr. Barwell suggested long since that the symptoms were due to the absorption of gonorrhœal pus, and others have held the same view. The hyperpyrexia in this case would seem to point very strongly to the septicæmic origin of the complaint, probably from the actual rupture of some small vein in the urethra, through which absorption took place.

In the case under review the hyperpyrexia came on within a few hours of the death of the patient. Previously the temperature had varied from 100° to 101.5° F., and there appeared no reason to apprehend a fatal issue. The thought occurs, may not a considerable number of cases of hyperpyrexia ordinarily attributed to rheumatism possibly have their origin in gonorrhœa? Is it altogether a mere coincidence that so-called gonorrhœal synovitis and hyperpyrexia of rheumatism should be so very much more common in the male sex? Even in ordinary cases of joint affections associated with gonorrhœa the existence of the latter has in most cases to be inquired for. Patients are usually very averse to the family medical attendant being made cognisant of the fact that they are suffering from the complaint. What is more likely therefore than that when rheumatic symptoms appear they should be reticent on the subject, especially as the discharge either ceases or becomes greatly diminished in quantity? If the case now reported should be held by the profession generally to point strongly

to a septicæmic origin of the complaint, would it not be well to discard the terms "gonorrhœal rheumatism," "synovitis," or "arthritis" in favour of "gonorrhœal septicæmia"? At any rate, it would have the effect of clearing the ground for a rational and possibly more successful treatment than exists at present, for if we cannot by any known drug kill the micrococci when they have once obtained access to the system, yet we can avoid doing harm by giving salicylates &c. which do not appear to have any very favourable effect on the disease. If given at the first onset of joint pain quinine in fairly large doses, combined with sufficient opium to control the pain, would on theoretical grounds appear to offer the best chance of success. The fatal result appears to have been due to the fact that the patient was somewhat advanced in years (sixty-two); that it was his first attack of gonorrhœa, and that his constitution was somewhat broken down from long years of alcoholic excess. The armies of the phagocytes, indeed, from their weakened powers of resistance, were worsted in their struggle for supremacy by the armies of the gonococci. Appended are a few notes of the case.

The patient, a man aged sixty-two, came to me on Aug. 10th, complaining of urethral discharge which had existed for about three days. He said that he had contracted the disease on July 31st. On examination there was a plentiful sanguineous purulent discharge; I ordered an alum and Condy injection and an alkaline mixture. On the 12th the discharge was much less, and he experienced very little pain on micturition, but seemed somewhat dejected, and complained of a little pain in the back. During the night of Aug. 13th he suffered great pain in the right wrist, shoulder and knee, and to a less extent on the left side also, being quite unable to move. Later in the day the right wrist became very swollen and inflamed, and there was considerable effusion into the right knee, but without any redness. The left ankle became both red and swollen, the left wrist painful, but not swollen; the soles of the feet painful when touched. The conjunctivæ and sclerotic of both eyes were injected. The temperature at noon was 100° F. I prescribed iodide of potassium and opium. On the 15th the pain was less and he had passed a fairly good night. The temperature at noon was 98.6°. The discharge from the urethra was very slight. The next day the right wrist was more swollen and inflamed, there being still more effusion into the knee, but no redness. Both ankles were somewhat swollen and red, and a slight muco-purulent discharge from both eyes supervened. The pain in the joints was not so severe, but he was unable to move them. The temperature at noon was 100°. On the 17th he did not complain of much pain, but the joints were swollen and inflamed still. Jokingly he said that he should like to go for a walk. He seemed quite sensible, but somnolent. Temperature at noon 101.5°; pulse 120, feeble. I was sent for to see him at 9 P.M. Soon after I left him at noon he had gradually sunk into a comatose condition and had been unable to speak or take any nourishment. At 10 P.M. he was in a deep coma. Temperature 107°. He died an hour later. It is to be regretted that no proper bath was available, and also that no post-mortem examination could be obtained.

Wood-green, N.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL.

#### A CASE OF POLYDACTYLISM.

By G. SYMERS MILL, M.B., C.M. EDIN.

THE following case may be interesting to the medical profession, as it is one of the greatest curiosity.

I attended M. S— during her confinement. She was a strong and healthy woman and had a perfectly normal labour. She was delivered of a strong and healthy male child. On examination, however, it was found that there were six digits on the left hand, there being two little fingers. The adventitious finger was well formed and similar to its fellow, with the exception of its attachment, which consisted of fibrous tissue and skin. The finger could be moved in any direction; it was attached to the ulnar side of the little finger. The other side was perfectly normal and showed no

<sup>1</sup> THE LANCET, Nov. 2nd, 1880, p. 901; quoted by the Year Book of Treatment for 1891.

vestige of an adventitious finger. The great interest of the case, however, is this, that of the six children she has had, four had more than the usual number of fingers, and all the adventitious fingers were to the ulnar side of the little finger. The first two of her children had perfectly normal hands, but the third had four little fingers, two on each hand. The fourth child had two little fingers on the left hand, the fifth had four little fingers, and the sixth was as described above. Another curious fact is that her brother's wife had a child with the condition of webbed fingers. Now, what are we to believe is the cause of this peculiar condition? I can hardly think it could be caused by maternal impression. My opinion is that it occurs in embryo by a process of dichotomy, there being a tendency in the cells which go to form the little finger in the ova of this particular woman to subdivide and form two fingers instead of one, although it seems strange that the first two children had normal hands.

Ossett, Wakefield.

#### GLYCOSURIA WITH LOW SPECIFIC GRAVITY OF URINE.

By B. H. NICHOLSON, M.B., C.M. EDIN.,

LATE RESIDENT SURGEON, ESSEX AND COLCHESTER HOSPITAL.

I HAVE lately been attending a lady whose case has interested me much, and after reading a recently published article by Sir Edward Sieveking the extreme rarity of the condition has further interested me, and I think it of sufficient interest to place before the readers of THE LANCET.

A lady aged sixty-five consulted me about two months ago, complaining of what she called "piles"—burning and itching of anus, dragging pains across the lumbar region and depression of spirits. She had been thus suffering for about a month. She had suffered occasionally before from pruritus and eczema of arms, neck &c., and her brothers and father being gouty also, I treated her condition accordingly. The patient stated that she had lost flesh since she had been suffering, and proved this by the misfit of her dress. Her muscles were flabby and wanted tone. The palmar surfaces of the hands were red and glossy and gouty in appearance. Her expression was anxious and worn and desponding from the continued itching and burning, which very much diminished her sleep. The tongue was clean, but rather red and irritable; appetite fair; very little thirst; sinking feeling after food, and occasionally acidity; bowels very irregular, and not moved without aperients; polyuria not marked, getting up twice at night; the heart, lungs &c. normal; the pulse 72, regular, good tension. There was a small papular, eczematous rash on the arms, legs &c., which itched very much. I obtained a specimen of the urine the following day: it was pale and limpid, with sp. gr. 1022, slightly acid. It yielded a trace of albumen with Esbach's solution of picric acid; and sugar was found on testing with Fehling's solution; on rough quantitative examination I found she was passing about four grains in the ounce of urine. On discovering the glycosuria the patient was immediately put on a strict diabetic diet, gluten bread &c.; strychnine, euonymin pill at night, with mineral water in the morning as aperient, and cocaine ointment to relieve the pruritus. In about three weeks she had completely lost her cares and troubles, pruritus and sleeplessness and also every trace of sugar, and the specific gravity went down to 1010. I kept her under strict diet for a month and then gradually allowed starchy food, but absolutely prohibited sugar and limited starch. The patient has remained quite well. The specific gravity of urine ranges between 1010 and 1014. The interest in this case lies in the low specific gravity combined with glycosuria and very little polyuria. I think in these rare cases we must assume the normal specific gravity to be 1010, and in glycosuria conditions 1022. This case shows the absolute necessity of careful chemical examination of the urine even with normal specific gravity.

Colchester.

#### REMEDIES IN SCORPION STING.

By R. P. BANERJEE, B.A., G.B., M.S.L.

BETWEEN April and June, 1892, I had an opportunity of treating forty-six cases of scorpion sting. Of this dreaded arachnid (*Scorpio afer*) there are four varieties: (a) A dark brown, (b) a reddish-brown, (c) one the colour of prepared

leather (pale yellow), and (d) one which is slate-blue. Of these the first and last are the most deadly. The first mentioned has the largest sting (half an inch long) and measures altogether four inches. The last, which is also most to be dreaded, measures from mandibles to telson half an inch to an inch and a half. The larger animal is sluggish and prefers dusty and manure-like soil; the smaller is found in stony places, abounds in the hills, and can endure extremes of temperature. My patients all suffered in the same way, with of course constitutional modifications. The part stung was reddish and oedematous and the pores of the sweat glands were unusually distinct. Severe burning pain was complained of in the part and extended rapidly. In some free perspiration occurred and was followed by much excitement and delirium. Females did not suffer much, and children wept much, but without exhibiting severe local effects. Men of strong build suffered most, and in some instances were very excited; but resolute persons expressed no great suffering. In all cases the joint above the part stung was almost stiff, and in some there were febrile symptoms with severe headache. Ten of my cases were treated with ipecacuanha poultices, as text-books recommend, but only with transient benefit, as I had in addition to use chloroform stupes. This relieved all pain, but the erysipelatous swelling of the affected parts remained, and continued in severe cases for seventy-two hours, requiring still further treatment. In two cases chloroform alone was used and gave instant relief, but swelling remained in this instance likewise. In five cases hydrate of chloral pure and simple was rubbed into the part. It answered well, relieving pain instantly, and with this remedy there was no subsequent swelling. The action of chloral was, moreover, less evanescent than that of chloroform. In order to use it in a more convenient and more rapidly absorbable form it was liquefied with the addition of camphor (three parts of chloral and one of camphor), and to render its action still more rapid the part was punctured with a pin or needle before its application. Menthol-camphor, and butyl-chloral-camphor were also found efficacious. Without wishing to depreciate the value of other methods this treatment, which I found successful in twenty severe cases, will, I trust, have a more extended trial from the profession in the tropics, in order that its value may be determined and its efficacy established.

Pachbudra, Rajputana, India.

#### DEATH FROM THE IRRITATION OF ASCARIDES.

By W. HENRY HILLYER, L.R.C.P. LOND., M.R.C.S.

ON Friday, Sept. 16th, I received a message to visit a child at a village some three miles off, who was said to have vomited worms and to be very ill. Having other, apparently more urgent, cases to attend, I did not see her until some three hours later, about 1.30 P.M. The patient, a child aged five years and a half, was lying on her back, half unconscious, with eyes wide open and dilated pupils. The conjunctivae were almost insensitive; the skin was cold and clammy; the temperature in the rectum was 99° 8'; the pulse was imperceptible at the wrist; the apex beat was fluttering and difficult to count, but was at least 200; the right hand was tightly clenched and there was some difficulty in getting the mouth open; the abdomen appeared normal. There was no distension and no lump could be felt on palpation. There was no specially tender spot, but the child moaned a little on being touched. The tongue was slightly furred and red at the tip.

The history of the case was as follows:—The child had never been very strong, but was in her usual health until the morning of the 15th, when she complained of severe abdominal pain. A dose of castor oil was administered, which was immediately returned, and with it three round worms. No further vomiting occurred, nor any action of the bowels, which had acted naturally the previous evening (the 14th). No worm had ever been passed per rectum. Since the vomiting of the worms the child had lain "just as you see her now," and had not complained of any acute pain, but moaned occasionally. She had never had any convulsions. I administered three grains of santalin, with three grains of calomel (which I had brought with me), but the child died ten minutes later without any change of symptoms.

On making a post-mortem examination twenty-two hours after death I found the small intestine slightly distended down to a point fifteen inches above the ileo-cæcal valve

where a mass of worms could be felt freely movable in the ileum. Below this point the bowel was collapsed and quite empty, except for two or three damson stones in the colon. The peritoneum covering the small intestine was slightly congested in patches, but not more so in one part than another. On opening the gut I found forty-two ascarides, of which eight were rolled together in a solid mass at the point noticed in the ileum, occluding but not distending the intestine. There was no perceptible narrowing of the gut at this point and no sign of intussusception. The mucous membrane was intensely congested throughout the small intestine, more especially about the occluded point. The stomach was empty and normal, and nothing abnormal was discovered in the lungs, brain, heart or any other organ.

The interest of the case centres in the question, "What was the immediate cause of death?" The symptoms were not those of acute obstruction, but rather of aggravated irritation of the bowel, and this was confirmed by the post-mortem appearances. It would appear as if the irritation had been sufficiently powerful to cause death from shock without the supervention of actual inflammation. Cases of death indirectly caused by ascarides, as by their escape into the abdominal cavity &c., have been frequently recorded, but I believe that a case of death either from the direct effects of their irritation or from obstruction by them must be exceedingly rare.

Buckden.

#### REFLEX SPASM OF GLOTTIS FOLLOWING DISTENSION OF STOMACH.

By SURGEON-LIEUTENANT B. G. SETON,   
 SECOND PUNJAB INFANTRY.

A MAN in the 2nd Punjab Infantry, a Tusufzai Pathan, was admitted to hospital on the night of Aug. 19th, with symptoms of laryngeal spasm. The patient had been on duty in an outlying fort for some days, and had been unable to get meat during that time. On his return to Fort Mastan on the evening of the 19th he ate a large quantity of very tough goat meat in pieces found subsequently to vary from four inches to seven inches and a half in length. This meat was uncooked. He then drank a large quantity of water. After his meal he sang for about an hour, at the end of which time he noticed occasional pain in his larynx and cough. This was gradually succeeded by dyspnoea, which finally prevented his sleeping, and at 1 A.M. he was taken to hospital.

On examination, beyond distension of abdomen, nothing was visible. As far as could be determined the obstruction to breathing was in his larynx. His speech was whispering and quite altered in quality. He also complained of some pain over the hepatic area. Hot fomentations were applied to his larynx, and occasional inhalations of chloroform were given, but their effect was transitory. No emetic could be administered as the spasm prevented him swallowing. At 2 A.M. counter-irritation was attempted, and blisters were applied along the course of the vagi, and cupping over his stomach repeatedly performed. The result was well marked in about half an hour, the spasms stopping for a time and then recommencing. Finally an emetic was given, and about a pound and a half of meat vomited. From this time his symptoms improved still more, though for three days he had a spasmodic laryngeal cough. Hepatitis came on the day after his meal, but was easily cured. No laryngeal examination could be made, as there was no instrument for the purpose at hand. It is important to note that when once the laryngeal symptoms began to abate the patient could swallow freely, so that direct pressure on the larynx by a mass of meat in the œsophagus was out of the question; while the marked effect of counter-irritation of the vagus seemed to point to the symptoms being due entirely to reflex irritation from the stomach. On Aug. 23rd all his symptoms had ceased.

Fort Mastan, Samana, Punjab.

**PUBLIC DISPENSARY, FALMOUTH.**—The medical report for the past year states that 456 patients had been treated during the twelve months. As far as known there were ten deaths, 104 cases cured, 300 relieved, 22 results unknown and 20 under treatment. The report concludes with the remark: "Very little sickness, and remarkably little of an epidemic character."

## A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

### ST. THOMAS'S HOSPITAL.

TWO CASES OF ROTATORY DISLOCATION OF THE PATELLA.

(Under the care of Mr. WM. ANDERSON.)

WITH regard to these cases Mr. Anderson has pointed out that they derive importance from their comparative rarity and from the extreme difficulty sometimes experienced in their reduction. In the published observations by Streubel about one-sixth of the patellar dislocations were rotatory, and of these about two-thirds were turned with the articular surface outwards, as in the examples now recorded. The mechanism of the displacement is by no means clear. Sometimes the accident is attributed to a blow, at other times to an attempt to recover from a false step, at other times to a fall, but there can be little doubt that in all it is a sudden and irregular contraction of the quadriceps that is the main factor. In Case 1 the patient felt the bone twist out of place while he was trying to regain his balance after a slip, and he was confident that he did not strike the knee; while in Case 2, on the contrary, there was a clear history of a blow on the outer side of the knee while the patient was rising from a kneeling posture. It has been found impossible to produce a rotatory dislocation artificially on the dead subject except by dividing the ligamentous structures and actually twisting the bone into its abnormal position by means of a lever introduced behind it, and from this we may assume that in any case mechanical violence applied on the living subject can only act by provoking the muscular spasm, which really effects and maintains the displacement. On theoretical grounds it would be difficult to imagine the extraordinary resistance offered by the luxated bone to the strongest efforts at replacement. Not the slightest impression could be made upon it in either of the following cases by very powerful leverage, although the patient was in a condition of surgical anaesthesia, with an apparently complete relaxation of the voluntary muscular system in general. In one case, quoted by Koenig, the bone is said to have defied reduction after the section of the ligamentum patellæ, and in another even after division of this and the tendon of the rectus also (Wolf). Gaulke succeeded by the use of a carpenter's vice, and others have achieved the end by introducing a lever or a hook beneath the bone through an opening on the capsule. It is probable, however, that the great element of success is to push the anæsthetic until it vanquishes the resistance of the quadriceps extensor, the tension of which persists long after the other muscles have become relaxed; and as adjuncts to this the movement of flexion with rotation appears to be more efficacious than simple extension, and possibly because it draws upon the margins of the twisted bone through the intermediation of the stretched tibio-patellar bands. In the second case no lateral band could be detected, and here neither flexion nor rotation of the leg produced any effect. Should all manipulations, aided by full anaesthesia, fail to reduce the bone, the methods referred to above would be justifiable if carried out with due precautions; but it may be borne in mind that, although some deformity and limitation of flexion would remain where reduction is not effected, a very useful command of the joint may be regained. A female patient once presented herself before Mr. Makins, with a rotatory dislocation of two years' standing, but she suffered so little inconvenience from the defect that it was not considered desirable to interfere. A cast taken from Cases 1 and another from the patient under the care of Mr. Makins, may be seen in the museum of St. Thomas's Hospital.

CASE 1 (from notes by Mr. R. B. Williams).—A. H—, aged fifteen, was admitted into Clayton ward on Feb. 26th, 1892. The patient slipped while walking, and, in endeavouring to regain his balance, the knee gave way beneath him. He says that it was not struck in the fall, but that on rising he found his knee fixed

in the extended position and very painful. When admitted he was a well-grown lad of good muscular development. The right knee was extended and the patella was found to be dislocated, with its outer margin turned forwards and the articular surface outwards, while the inner margin rested between the condyles. The outer border of the rectus was very tense, and a tight ligamentous band extended from the projecting margin of the bone to the inner tuberosity of the tibia. The patella was quite fixed. Chloroform having been given, an attempt was made to restore the bone to its normal position while the limb was extended, but no exertion of force made any impression upon it. The quadriceps still remaining tense, the anæsthesia was pushed further, and then on flexing the joint about forty degrees and manipulating the patella the dislocation was reduced with very little effort. The limb was bandaged and placed upon a back splint. Some little effusion into the joint followed, but no other symptoms arose, and at the end of three weeks the patient left the hospital.

CASE 2. (from notes by Mr. J. R. Carver).—A. R.—, aged twenty-three, domestic servant, was admitted into Elizabeth ward on April 21st, 1892. The patient while rising from a kneeling position on the floor slipped and struck the outside of the left patella against the corner of an arm-chair. Feeling great pain in the knee and inability to flex the joint, she went to a local practitioner, who recognised the nature of the accident and endeavoured, but unsuccessfully, to reduce the dislocation. She was then brought to the hospital. The patient on admission was a stout but somewhat unhealthy looking young woman. On examination of the knee the patella was found to be dislocated, with its articular surface turned outwards, the position being identical with that in Case 1. There was strongly marked tension of the rectus, but the tibio-patellar band seen in the last case was not apparent. After the administration of chloroform attempts at replacement were made, first during extension and afterwards by flexion and rotation of the leg, but although considerable force was exercised the bone was absolutely immovable. The quadriceps still remained very rigid although the rest of the muscular system appeared to be relaxed, but on pressing the anæsthetic further the tension diminished, and during a gentle manipulation, while the knee was extended and the thigh flexed, the bone returned to its place with a sudden spring-like action. The after treatment was the same as in the previous case. The patient was discharged at the end of a fortnight.

### VICTORIA HOSPITAL, HULL.

#### OSTEOMYELITIS OF TIBIA; RESECTION; MULTIPLE (SEPTIC) EPIPHYSITIS.

(Under the care of Mr. ALFRED PARKIN.)

THIS case illustrates well what is now by no means a common form of bone pyæmia. The original mischief in the tibia undoubtedly gave rise to suppuration in the elbow-joint, probably, as afterwards found out, by a deposit in the lower epiphysal line of the humerus; and subsequently affections of the other bones resulted, from similar depositions of embolic foci, so that in all five bones and two joints became involved. It was remarkable how few symptoms there were to indicate what proved to be extensive mischief in each case. Slight swelling about an epiphysal line and around the epiphysis was the first thing noticed; pain or tenderness on pressure only developed late, and it was impossible to be certain of the affection of any one bone until a portion of the compact tissue had been removed by a gouge. Drilling the bone was useless, the caseous matter being too thick to escape in this way, and yet if that caseous matter had not been removed the chances of recovery would have been small.

R. P.—, aged ten, was admitted to the Children's Hospital, Hull, on Jan. 25th, 1892. He had been ill and in bed about three weeks suffering from a bad leg, the result of a kick. On admission he was pale and emaciated and complained of pain in the left leg, which was swollen. Over the centre of the tibia there was a sinus discharging pus freely, and around it much redness and œdema, with marked thickening about the upper two-thirds of the bone. The left elbow-joint was swollen and very painful, with fluctuation behind. Evening temperature 103°.

Jan. 26th.—The tibia was explored and a large part of the shaft found bare and yellow. A portion of the whole shaft (five inches in length) was removed. The periosteum around it

had begun to form new bone, which lay in isolated plates on the walls of the cavity from which the dead bone was removed. The medulla of the removed bone was full of pus of an offensive odour. The resected ends of the tibia were scraped out and the cavity well drained. The left elbow-joint was opened and a quantity of pus escaped. The cartilages felt firm and movement was quite free and smooth, so the joint was irrigated and drained.

Feb. 3rd.—The temperature, which had come down after the operation, has for the last two evenings been 104°. A large abscess over the external condyle of the left humerus was opened and drained. It did not apparently communicate with the elbow-joint.

22nd.—The temperature is still 101° or 102° at night. For the last six days there has been slight thickening around the head of the right ulna. Not the slightest tenderness on pressure, merely a diffuse swelling. The swelling has been explored and the bone drilled without result. On removal of a part of the compact tissue the medulla was found to be full of caseous matter extending along the lower third of the bone. This caseous matter was all scraped out.

28th.—The right tibia near the ankle is swollen and tender on exploration. The bone is found to be very soft and the medulla easily opened up at the epiphysal line. Pus was found running in different directions along small channels in the bone, some of which extended almost to the ankle-joint.

13th.—For the last three days slight thickening has been noticeable around the lower end of the left radius; to-day a little tenderness is present on firm pressure. The general condition of the patient is excellent. The left radius was explored and the lower end found to be full of pus, which had burrowed through and in front of the bone. A part of the lower end of the radius, including a portion entering into the wrist-joint, came away quite dead and devoid of articular cartilage.

April 2nd.—Marked thickening shows itself over the upper end of the right humerus. There is slight pain on pressure, but no redness or œdema. On exploration an aperture at the epiphysal line was found, and from this a large cavity full of broken-down material extended upwards into the head of the bone, nearly to the articular cartilage, and downwards for about an inch along the medulla. The left elbow-joint was excised on the supposition that it was a centre of infection; the cartilages were soft and not easily raised; extensive caries was found in the olecranon fossa.

18th.—General condition of patient excellent. A large abscess over the external condyle of the left humerus was opened and drained. The patient can now walk quite well and without limping; left leg quite straight; a firm mass of bone occupies the situation of the part of tibia removed.

25th.—The temperature is now normal, all the wounds healing up well.

June 10th.—Went to a convalescent home. Good movement of left forearm and hand and the muscles are increasing in size. Active flexion of forearm to an angle of 30°, extension to 135°; pronation and supination of hand 90°. Excision wound quite healed. Good movement at left wrist-joint; other wounds practically healed.

The case is an excellent example of the results of epiphysitis or, as some would call it, par-epiphysitis, the mischief readily extending along the epiphysal line to the outside of the bone, along the medulla, into the epiphysis or into the neighbouring joint. Fortunately in each case the disease was controlled before any one of the epiphyses had become separated, and there is no doubt that in similar cases life can only be saved by a ready resort to operation as soon as any swelling is detected. The mischief extends so very rapidly that it is worse than useless to wait until pain or tenderness appears, not to mention redness or œdema. A swelling about an epiphysal line is in itself a sufficient indication for exploration, and it will be strange if in any such case the extent of the disease is not found to be much greater than anticipated. Another feature in this case was the rapidity with which new bone was reproduced after the removal of five inches of the tibia. In about nine weeks the patient was able to walk quite well, and yet at the first operation the periosteum lining the cavity was only covered here and there by a little plate of bone. Anyone who has seen and smelt the yellowish-green material filling the centre of a long bone affected by osteomyelitis will recognise the magnitude of the danger to which a person is exposed until that bone is removed; and, when to this is added the factor that the sooner all dead bone

is removed the sooner can the periosteum begin to produce healthy bone, it is evident that we have here two powerful arguments in favour of early bone resection in such cases. It is only by prompt eradication of all septic foci, so preventing further (perhaps visceral) dissemination, that we can hope to save the life of the patient, or avoid months of troublesome suppuration with its attendant dangers.

## Reviews and Notices of Books.

*Diseases of the Nervous System.* By JEROME K. BAUDUY, M.D., LL.D. Philadelphia: J. B. Lippincott Co. 1892.

THIS is a book of 350 pages, the second edition of a work published in 1876. A second volume is promised in which brain diseases, spinal cord conditions and peripheral affections will be discussed; so that the work when completed may be expected to be very comprehensive. From the volume before us it is not easy to discover the plan on which the book is framed. It consists of nineteen lectures, and of these no less than eight are devoted to the subject of insanity in its various phases. We may say at once that the book is somewhat disappointing both as regards matter and style. However necessary or justifiable the presence of lengthy quotations from more or less classical works may be in a systematic treatise they are quite unsuitable, we think, in a work cast in the form of lectures, and the impression which such an arrangement conveys is that the author has not taken the trouble to assimilate the various views which have been stated, but, has been content to transfer to his pages, with due acknowledgment of course, extracts from the numerous works he has consulted. The result of this is a want of conciseness and cohesion in the matter and makes it difficult for the reader to arrive at the author's own views, which are evidently the result of large experience and acute observation. As we have said, no less than eight lectures deal with insanity; the other eleven are devoted to the consideration of anæmia and hyperæmia of the brain and affections of the cerebral meninges. In the next volume we hope the author will do himself greater justice than he has in the one before us.

*Les Troubles du Langage chez les Aliénés.* Par J. SÉGLAS. Paris: J. Rueff et Cie. 1892.

IT is unnecessary to do more than indicate the scope of this valuable monograph. The subject with which it deals interesting scientifically is also of great practical importance, and the author is to be congratulated on the manner in which he has done his work. The book is divided into three parts, prefaced by an introduction and two preliminary chapters. The first part deals with abnormalities in spoken language. These are discussed under three heads—viz., abnormalities in speech the result of intellectual disturbance; abnormalities of speech with disturbance of the speech function proper; and troubles in talking. Similarly, written speech is discussed on analogous lines, and finally imitative speech. This brief *résumé* of the contents will give an idea of the completeness of the plan of the work; perusal alone will reveal the excellence with which it has been carried out.

*Die Mikro-organismen der Gärungsindustrie.* Von ALFRED JÖRGENSEN. Dritte neubearbeitete und vermehrte Auflage. Mit 56 Textabbildungen. Berlin: Verlag von Paul Parey. 1892.

IT will be remembered that in 1889 an English translation of Jörgensen's work, edited by Dr. G. H. Morris, was placed in the hands of students of bacteriology; this was exceedingly well received, and very rightly so, as it gave an account of the processes of fermentation as applied to brewing such as had not hitherto appeared in our language. It contained much matter that was not given in the original, but was still not so fully up to date as the second German

edition, which appeared in the same year. So successful has the book been abroad, and so greatly in demand, that we have now before us a third German edition. The original work is so well known that little need be said in its praise. It has, since its first appearance, been the standard reference book for those engaged in industries in which fermentative processes play a part, and it certainly promises to retain its position since it has been brought up to date. Not only is the text expanded and corrected, but the illustrations are very considerably increased in number. This is specially noticeable in the section devoted to the Multiplication, Spore Formation and Sprouting of the Saccharomycetes—a section which will well repay perusal by all students of botany and bacteriology. It may be added that, though this work was written expressly for the technical student, the subject matter is treated in such a thoroughly scientific manner that parts of it might almost be used in place of a biological text-book. A short *résumé* of work initiated or influenced by Hansen's researches is given in a supplementary chapter, and a very full bibliographical list is appended.

*The Hygienic Treatment of Consumption.* By M. L. HOLBROOK, M.D. London: L. N. Fowler, Ludgate-circus. 1892.

THIS is a popular exposition of the causes, prevention and general hygienic management of phthisis. It is written for the patient, "as the author believes he can under most circumstances do most for himself, and also be better able to coöperate with his physician at the same time." Medicines are ignored, the author believing that "at most little benefit can be derived from them, and a reliance on their supposed virtues is sure to attract ('distract) the patient from the remedies here recommended." After a brief consideration of the causes of phthisis the author deals at length with the means to be taken for enlarging the chest, for promoting respiratory power, for strengthening and hardening the constitution &c. The questions of food, exercise, clothing, house hygiene, climate and travel and the cultivation of brain power are passed under review. Much of the advice given is sound and sensible, and such as every physician of experience is in the habit of giving to his phthisical patients. The two chapters on vocal exercises are the best in the book, and are worthy of the attention of invalids. There can be little doubt that much remains to be done in the direction of special pulmonary exercises, and that singing and reading aloud can be most advantageously used for this purpose. The subject of climate is very briefly handled, and nothing new is said regarding it. Dr. Holbrook praises highly the region around Florence (Arizona) and Sevier Valley in Utah as valuable sanatoria for the poitrinaire. The author is a great believer in "psychic influence" and the cultivation of the will, and relates several anecdotes of patients who, learning that they were affected by phthisis, resolved to get well, and succeeded largely, he thinks, by sheer will force. Perhaps owing to its popular aim the work has little scientific value. The physiology is often hazy, and many important points are slurred over or dismissed in a vague sentence or two. Here and there occur passages that excite a smile. Thus we are told that "what is called magnetic treatment has its value if taken once or twice a week, provided a healthy person gives it" (p. 211); and in choosing a house, Dr. Holbrook, among other instructions advises the patient to inquire "if any room is haunted" (p. 142).

*La Débauche.* Par ÉMILE ZOLA. Paris: Bibliothèque Charpentier. Pp. 636. 1892

ENGLISH readers have not become enamoured of M. Zola's realistic literature, and we remember that not so long ago the liberty of one of Her Majesty's subjects was imperilled for

doing into English some of this writer's most popular novels. Stung apparently by the criticism that he could not write a clean book, M. Zola gave "Le Rôve" to the world, expressly for the Young Person, and now "La Débâcle" has well proved itself worthy of criticism by its number reaching in a few weeks 120,000. One of the first incidents having an interest for medical readers in the novel is pictured as occurring before Sedan, a child of ten being unable to be transported to the rear because he is suffering from typhoid fever. His devoted mother remains with him, and is killed on a doorstep by a stray shell. The poor child, in raging fever, begs piteously for water, but his hearers are too intoxicated by fighting to pay the least attention to him. As the battle proceeds soldiers overcome by fear are described as losing control over their sphincters, while Napoleon makes heroic attempts to disguise his sufferings, and is rewarded for his courage by nights of torture only relieved by groaning. A first dressing place is formed for the wounded, civilians and ladies are pressed into the service to roll bandages, and improvised splints for fractures are described. In Sedan itself a station hospital was established in a convenient warehouse, and some thirteen pages are devoted to a faithful description of the operations conducted there by Surgeon-Major Bourroche. Those who remember the carnage of Sedan, Metz, Plevna and Shipka can well sympathise with the operator who, without adequate assistance, in choosing suitable subjects for the table, had to turn a deaf ear to most of those who were slightly wounded. In an atmosphere nauseated by blood and chloroform, surrounded by the dying and the dead, he disarticulates a shoulder by Lisfranc's method in thirty-five seconds, then amputates a leg by the circular method below the knee, taking care to divide the skin two inches below the point where he intends to saw the bones. While the operator is dividing the muscles from the tibia and fibula an attendant whispers in his ear that the next operation, "the arm," is dead. "Ah, well! bring the next one—the jaw." As the operation is being finished a shell bursts in the courtyard, completing the terror of the wounded, the bearers and the amateur assistants; and so the scene at the shambles continues till nightfall, and again the following day, till at last the chloroform is exhausted and the stern enemy will allow none to be admitted into the town. The surgeon-major is beside himself with fatigue and vexation, as he has 400 wounded to treat and his entreaties for help have only brought him one young assistant. The contagion of fear among young soldiers is well described, and we are irresistibly reminded of scenes even better told in Tolstoy's war stories. In another chapter we can easily picture a handful of French troops caught in a wood near Sedan and peppered so hotly by the enemy's fire that most of the little band are killed or wounded, and many are the execrations on the sun, which seemed never to be setting and never to be ending the dangerous day. The chief object of the author is to show that though the bulk of the French were brave enough their officers were hopelessly ignorant, ill-prepared, and unfurnished with maps of France, though they all had survey maps of Germany. One general ordered his men to cross the Meuse, the Moselle, or "whatever other river it was in front of them." After the fall of Sedan thousands of French prisoners were encamped on a peninsula formed by the Meuse. Here they suffered terrible privations from the failure of the German commissariat; so that eventually the hero and his comrades were driven by hunger to kill a dying horse with a pen-knife, by stealth, and eat it while half raw, without salt, bread or biscuit. Their stomachs fortunately refused this doubtful food, weakened as they already were by dysentery consequent on drinking river water poisoned by numberless corpses of men and horses. A few days later one of this company was suspected of having a secret supply of food, chiefly because he had ceased to complain of hunger. Thrice

of his comrades, by this time wholly brutes, found him eating half a loaf of bread, chased him, and eventually the least human of them killed him with the knife as he had killed the horse shortly before. It is satisfactory to note that the murderer, after bolting the bread, was shot by the sentries while trying to escape by swimming the river. The hero escapes from these dangers, finds his way into Paris, deserts there, and is eventually bayoneted by his chief friend, who does not recognise him in a Communist blouse. The friend was shot in the leg, however, before Paris was invested, and a long illness resulted, during which he was hidden on a French farm and tenderly nursed by the hero's sister, whose husband had been killed before her eyes by the Bavarians. The details of the wound are described with the care and technical knowledge for which M. Zola is justly remarkable. "Jean's wound healed extraordinarily slowly, the drainage-tube not always yielding laudable pus, which would have justified the doctor in operating, while the patient gradually weakened, obstinately refusing any operation for fear of becoming crippled." However, patience and good nursing, with a splendid constitution, pulled him through, and away he went wholly in love with the widowed nurse. Less fortunate than this were many of the wounded, who were found ten days after the fighting with their wounds alive with maggots. What wonder that they succumbed later to septicæmia, dysentery, typhus fever and hæmorrhagic small-pox. The medical descriptions are wonderfully accurate, though we may venture to doubt whether the delirious, dying of pneumonia, were wracked by terrible coughs. "Every day, at the dressing hour, the doctor examining the wounds was distressed to find bluish marks on some poor devil's skin, the sign of hospital gangrene." In spite of free amputation the patient was soon found in "the condemned ward, where he breathed his last, his body already dead and practically a corpse before the final dissolution." The book faithfully describes the treatment of wounds as it was on battlefields and in crowded hospitals in 1870, before the days of antiseptic surgery. There is no mention of the help rendered at Sedan by the Anglo-American ambulances. There is much in "La Débâcle" to entertain both professional and other readers, and we shall be interested in the future in seeing how M. Zola treats the subject of the supposed cures during the Lourdes pilgrimage, a study on which, we understand, he is at present engaged.

*The Holiday Annual, a Handbook of Practical Information on Holiday Topics.* Edited by A. B. C. London: Causton and Sons, 9, Eastcheap, E.C.

ANNUALS of this kind are among the many indications of the enormous development of holiday travel in these days. The annual before us contains papers on Spain, France, Switzerland, Arcachon, Lakeland, the Norfolk Broads, Dublin as a holiday centre, Kairwan "the holy," Penmaenmawr, North Wales &c. Here is variety enough for all tastes. The articles for the most part have no pretensions either to literary style or scholarship and deal as a rule only with obvious facts and superficial impressions. But they may be read with advantage by those meditating a holiday tour and may be the means of arousing pleasant recollections of by-gone travel on the part of others.

*Psycho-therapeutics, or Treatment by Hypnotism and Suggestion.* By C. LLOYD TUCKER, M.D. London: Baillière Tindall and Cox. 1891.

WE have little to add to what we said in our notice of a former edition of this book. It has been considerably enlarged, and contains accounts of interesting cases collected from various sources.

*Hoblyn's Dictionary of Medical Terms.* Edited by J. A. PRICE, B.A., M.D. Oxon., Assistant Surgeon to the Royal Berkshire Hospital and late Physician to the Royal Hospital for Children and Women. London: Whittaker and Co. and George Bell and Sons.

THIS well-known work of the late Richard D. Hoblyn, M.A., has now passed through its twelfth edition, having been thoroughly revised and brought up to date by Dr. J. A. Price. Many new words have been added to the work, more especially in the department of bacteriology, and a useful feature of this new issue is the addition of dates to the names of eminent medical men mentioned in the work who have passed away.

THE *Veterinary Journal* for August as usual contains a considerable quantity of very interesting matter. The original articles are on "Acute Gastritis in Cattle, commonly known as Grass Disease," by J. Clark, F.R.C.V.S., Coupar Angus; "Diseases of Horses in Mashonaland," by Dr. Rayner, Cape of Good Hope; "Lameness from Enlargement of the Inferior Tuberosity of the Small Metacarpal Bone," by Veterinary-Captain J. A. Nunn, F.R.C.V.S., D.S.O., Principal, Lahore Veterinary College, and Veterinary-Lieutenant L. J. Blenkinsop, M.R.C.V.S., Veterinary Surgeon to the Punjab Government and Professor at the Lahore Veterinary College; and by the same authors, "The Use of Cocaine in Masking Lameness"; and an article on "Sciatica" by John Scott, M.D.V. An editorial article which will be of more than veterinary interest at the present time, in view of the prevalence of glanders in London, deals with Mallein as a Diagnostic Aid in Glanders; this diagnostic agent has been utilised both in Russia and in France and it seems probable that it might be of some service in London. Reviews, reprints and reports—amongst the latter a report of Mr. T. B. Goodall's paper on the "Nasal Chamber and Facial Sinuses of the Horse," read before the Royal Counties Veterinary Medical Association—will prove of very considerable interest. This paper is characterised by very careful observation and close reasoning and is well worthy of perusal by both veterinary and medical authorities.

## Analytical Records.

### TABLOIDS OF COMPRESSED RESORCIN AND TABLOIDS OF COMPRESSED ICHTHYOL.

(BURROUGHS, WELLCOME & Co., SNOW-HILL BUILDINGS, E.C.)

RESORCIN is antipyretic, antiseptic and hæmostatic, and it may be administered very readily and conveniently in the form of the three-grain tabloid which we have recently examined. Resorcin belongs to the group of diatomic phenols, just as pyrogalllic acid belongs to the group of triatomic phenols,  $C_6H_3(OH)_3$ , and is isomeric with pyrocatechin and hydroquinone, the formula  $C_6H_4(OH)_2$  being common to the group. It gives a dark violet colour with iron perchloride and with chloride of lime, but the most interesting reaction perhaps is that in which, when treated with sodium nitrite, it produces lilmoid, a magnificent blue colour strongly resembling litmus. All these reactions were successfully obtained with the resorcin tabloid.

Organic compounds of sulphur are invariably nauseous to the taste and smell, and ichthyol is no exception to the rule. Ichthyol, or more exactly sulpho-ichthyolate of sodium, is a bituminous substance obtained by treating with sulphuric acid; and subsequently neutralising with an alkali, the products of distillation of a bituminous quartz (fossil fish remains) found in the Tyrol. By abstracting oxygen from the tissues it becomes a reducing agent of some value and is reputed to exert an invigorating and antiseptic influence throughout the organism, as well as an astringent effect on the bloodvessels; so that its use is suggested in cases where

there is dilatation of the capillaries. The tabloids of compressed ichthyol prepared by the above firm consist of the medicament in a massed form, enclosed in a coating of pure cane sugar, and as by this means the objectionable taste of the ichthyol is completely hidden, the usefulness and convenience of this method of administration are again evident. On heating the brown mass in a test-tube it rapidly swells up and gives off tarry oils possessing a strong alliaceous odour. When the drug is ignited with nitrate of potassium it deflagrates brilliantly and yields its sulphur to the potassium salt, so that on dissolving the "melt" in water sulphate is found to be present according to the barium test. Each tabloid contains two grains and a half of ichthyol.

### STARCHLESS BISCUITS.

(J. J. CLARK, GOLDSTONE BREAD FACTORY, WEST BRIGHTON.)

An analysis of these biscuits shows that they contain all the food constituents of flour minus the starch. Our own analysis, which approximately agrees with that submitted to our notice, gave the following results: Moisture, 2.51 per cent.; mineral matter (especially rich in soluble phosphate), 5.56 per cent.; albuminoids, 43.47 per cent.; extractives and soluble matter, 30.0 per cent.; fat, 18.46 per cent. Microscopical examination confirmed the foregoing analysis; there was no starch and no bran. The biscuits are exceedingly palatable, crisp and of excellent texture, and from the fact that they contain no glucose-yielding substances may well be included as acceptable and valuable food stuffs in the dietary of diabetic patients.

### ARMOUR'S ESSENCE OF PEPSIN.

(MESSRS. ARMOUR AND CO., 59 AND 60, TOOLEY-STREET; AND CHICAGO.)

Laboratory experiments furnished unmistakable evidence of the value of this preparation, inasmuch as it was found to be remarkably active in digesting hard-boiled egg, which it readily converts into assimilable peptone. Notwithstanding this activity, the essence possesses a very satisfactory flavour and odour, and, indeed, in these two respects more nearly resembles a sweet wine than a preparation destined to materially assist digestion. It is acid to test paper, and in appearance might be mistaken for sherry. Armour's essence of pepsin is a distinct advance on ordinary preparations of this class. It may be regarded as a reliable and agreeable form of pepsin wine.

### LIQUOR MANGANO-FERRI PEPTONATI.—SAPO EUCALYPTI ET ACID. CARBOLICI.—IMPROVED PATENT SEIDLITZ POWDER.

(HOCKIN, WILSON AND CO., 13-16, NEW-INN-YARD, 186A, TOTTENHAM-COURT-ROAD, W.)

Liquor mangano-ferri peptonati is a clear dark-brown liquid smelling of cloves; it is acid to test paper and contains 0.6 per cent. of iron with 0.1 per cent. of manganese. The iron is in organic combination, as is evidenced by the following tests: Ammonia gave no precipitate and potassium ferrocyanide or sulphocyanide no result till acidified with hydrochloric acid. Ammonium sulphide produced an immediate black precipitate. Manganese was separated and subsequently recognised by the test which depends upon the formation of green manganate when the metal and its compounds are fused with soda, and upon the formation of red permanganate when the alkaline mass so obtained is acidified with sulphuric acid. In spite of the presence of these metals peptone was discovered by the biuret test. It is an ingeniously prepared and reliable product and may doubtless be administered with distinct advantage in cases where the readily oxidisable metals present are indicated. Moreover, it is agreeable to the palate and devoid of styptic taste.

Sapo eucalypti et acid. carbolici, as its name implies, contains a judicious proportion of the readily volatile antiseptic eucalyptus with the less readily volatile carbolic acid. The soap with which these agents are incorporated is entirely free from excess of moisture and alkali, and gives, not too rapidly,

an excellent lather. To the practitioner a soap of this kind is of course invaluable, and obviously it may be used with benefit in the toilet, bath or nursery.

The seidlitz powder is a preparation of the highest order; it is readily soluble in water, effervesces briskly and is not disagreeable in taste. Although it is hardly correct to describe it as being composed of the ingredients of the German Seidlitz Spa, seeing that it contains no magnesium salts, it is equally effective and probably more agreeable.

#### CORBOLD'S SANITARY WHITING.

This preparation is regarded as sanitary because it is impregnated with camphor. The presence of camphor is pretty evident from the smell, but analysis shows the proportion to be very small. At its best camphor is but a feeble antiseptic. It has a popular reputation for keeping away moths, flies and similar pests, and for this purpose the whitening may be perhaps used with some advantage.

#### CIDER AND PERRY.

(JAMES HARPER AND SONS, EBLEY, NEAR STROUD, GLOUCESTERSHIRE.)

Cider is a beverage of some antiquity, and when of good quality and in good condition is no doubt a wholesome beverage. As is well known, it is made from the saccharine juice of the apple, just as perry is made from the juice of the pear, and it accordingly contains acids (chiefly malic), extractives (sugar) and salts (the carbonates and phosphates of potassium). The samples submitted to us by the above firm are thus described: 1. Royal Wilding "Harper Brand," 1880 vintage. It yielded the following results on analysis: Alcohol, 2.70 per cent. by weight, or 3.40 per cent. by volume; extract, 8.16 per cent.; and mineral matter, 0.32 per cent. The mineral matter consisted of alkaline phosphate and carbonate and contained distinct traces of iron. 2. Best English champagne perry. This liquor gave the following results: Alcohol, 1.45 per cent. by weight, 1.80 per cent. by volume; extract, 11.00 per cent.; and mineral matter, 0.35. The ash consisted, again, of alkaline phosphate and carbonate, and contained a very distinct quantity of iron. 3. Newtown pippin cider on analysis gave: Alcohol, 0.95 per cent. by weight, 1.20 per cent. by volume; extract, 9.78 per cent.; and mineral matter, 0.29 per cent. The ash was practically the same as No. 1. 4. Best American champagne cider contained 1.95 per cent. alcohol by weight, 2.45 per cent. by volume; extract, 11.26 per cent.; and ash, 0.32 per cent. The flavour and general character of Nos. 1 and 3 were of special excellence. As evidence of the genuineness of these preparations it may be mentioned that the acid of the fruit (malic) was successfully separated from each and identified. Samples 2 and 4 contained a distinct though small quantity of an added antiseptic. The samples are evidently prepared with care; they were in excellent condition and agreeably sparkling.

#### UBONE FOOD.

(BONNECHOSE AND CO., YORK-STREET, LIVERPOOL.)

Ubone food is described as a phosphatic pepto-pancreatised food. However this may be, we found it to consist largely of dextrin yielding 1.63 per cent. of mineral matter abounding in phosphates of lime and potassium, together with common salt. The preparation contains, in fact, more than double the amount of valuable mineral constituents of good wheat flour. In the face of these results it cannot be doubted that "ubone" possesses highly nutritious qualities of a certain kind, but we should like to have some evidence of the claim that it "digests itself." We emphatically object to the statement that "it supplies all the elements called for, and excludes everything that is objectionable in dealing with the 'scourge' of diabetes." On the contrary, a food such as this, containing as it does a remarkably high proportion of sugar-yielding carbo-hydrate, should of course be rigorously excluded from the diet of diabetic patients, to whom, indeed, it might probably cause very serious mischief.

## "THE ETHICS OF OPIUM AND ALCOHOL."

To the Editors of THE LANCET.

SIRS,—As one of the signatories to the document which in December last, was sent to every member of the profession, and which in your issue of Sept. 17th is characterised by Dr. Mouat as "one of the most mendacious" he had ever read, I would crave space for a very brief comment on that allegation. It is hardly complimentary, to say the least, to the intelligence of the profession that on a great public question like that of our Indian opium trade its members should be judged incapable of weighing at its proper value any statement which might be placed before them. Neither is Dr. Mouat over-complimentary to himself when he affirms his own consciousness of a grievous deception being practised upon the profession, and yet delays *nine* months to call attention to our extrememendancy. One is rather inclined to believe that had it not been for Dr. Pringle's pungent criticisms on Dr. Mouat's former letter we might have escaped altogether this late but terrible exposure. In any case it is a little preposterous that four medical men who have spent the best part of their lives in the East, who have had extremely close contact with this opium question, not only in vast numbers of opium patients, but in earnest study of the possible means of removing a great evil, should have a charge of extreme mendacity thrown at them because their opinions differ from those of Dr. Mouat. Dr. Mouat had no right to bring such a charge without attempting to substantiate it. Beyond making the specific statement he does not add one word of explanation. And this, too, in a paper dealing with ethics! Alas, poor ethics!

Let us recall the statements of the maligned document (I have sent an extra copy to Dr. Mouat for his further study). It consists of five paragraphs. The first sets forth the opium monopoly of the British Indian Government; how, according to the fluctuations of the Chinese market, the Government restricts or extends, as it pleases, the acreage of poppy cultivation; how it does this by granting or withholding licences to grow the poppy, and how the whole is manipulated with a single eye to revenue. The second paragraph asserts that the present enormous growth of the poppy, not only in British India, but also in the native states, is the result of a policy steadfastly pursued by the Indian Government during the last hundred years, and that the increase of the opium export from a few hundred chests towards the close of last century to an annual average now of 90,000 chests has been due to the one consideration of revenue. Paragraph 3 calls attention to the severe restrictions which, in the earlier days of the monopoly, the East India Company exercised over the sale of the drug in India itself, avowedly to save its people from a dangerous vice; and points out that the Company failed to realise that increased cultivation by the peasantry was bound to lead on to increased consumption in India itself. Paragraph 4 tells us how in 1871 Sir Cecil Beadon testified before a Committee of the House of Commons that with regard to opium consumption in India the only consideration which then guided the Government was to get as much revenue out of it as it possibly could. Sir Cecil Beadon had been Lieutenant-Governor of Bengal and at the head of the opium administration, and knew what he said. The paragraph further points out that besides this diminished sensibility to the evil on the part of administrators a largely diminished revenue from opium sales due to Chinese competition explained a steadily extending sale of the drug (the paper says "all over India," but "in many parts of India" would be more correct), so that the use of opium among our fellow subjects there threatens to become as widespread a curse as it is to-day in China. Paragraph 5 points out that the facility of purchase and practical invitation to it by the signboards of vendors in the public streets not only encouraged the spread of the opium habit, but opened the door in India, as in China, to innumerable acts of suicide, as also to the quiet but willful murder of little children and to the widespread inoculation of children with the opium craving through the practice of mothers narcotising their children while they themselves are at work; and after quoting the opinion of so distinguished a Chief Commissioner of Burmah as Sir Charles Aitchison on the lamentable effects of British opium policy in Burmah, the paper concludes with an appeal to the members of the profession to join in an expression of opinion on the subject which might bring about a better state of things. Will Dr. Mouat kindly state on what grounds he bases his extraordinary and I must add his unworthy charge?—I am, Sirs, yours truly,

J. L. MAXWELL, M.A., M.D. Edin.

Highbury-park, N, Sept. 20th, 1892.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 1, 1892.

THE dilemma of the Metropolitan Asylums Board continues and shows no sign of abatement. The Board is required daily to put a quart into a pint pot, or, at any rate, to find accommodation for a much greater number of cases than it has room for. The Board is not to blame for this run upon its beds. Some may think that the hospitals are attempting too much and making their accommodation too easy and cheap. But the Managers are not to blame; they have simply no option in the matter. Parliament has itself thrown the hospitals of the Board open to London generally, irrespective of class or the financial position of applicants. Consequently the officials of the Board make no troublesome or inconvenient inquiries into the social or financial position of patients. Admission can be gained without any application to the parish authorities (the very poor generally do apply through a medical officer of health) and when gained it involves no social discredit or disqualification. We must all admire the efforts of the Managers of the hospitals to meet the demand; and we may give Parliament credit for thinking that it was doing a wise and benevolent thing in practically opening the hospitals to all comers, on the principle of first come first served. But the unmistakable dilemma in which the Board finds itself compels a distinct reconsideration of the question. On one point there will be universal agreement—that the poor should have the use of the hospitals. It admits of no discussion that a sanitary authority which does not provide the means of isolation for cases of serious infectious disease in houses where isolation is impossible is neglecting one of its primary duties. But it does not follow from this that the sanitary authority should be required to provide isolation hospitals simply to relieve well-to-do families of the inconvenience of treating such cases at home. We have not the means of judging what proportion of the cases actually admitted come under this description. Perhaps Sir EDWIN GALSWORTHY, in his next statement—which is anxiously looked for—will be able to give the public some information on this point. Not very much, we fear, for the Board, as we have said, makes no definite inquiries on the subject. But it can scarcely be doubted that cases which need hospital accommodation are kept out by the admission of patients that could be isolated at home or treated in other institutions on private terms. This is the old case of hospital abuse in a very questionable form. Many simple people think that if only the State takes things in hand all is right, and they imagine that all the evils known as hospital abuse would vanish if these institutions were placed under State control. The dilemma of the Metropolitan Asylums Board does not lend much support to this view. Rather it suggests an indefinite and what might become a demoralising extension of the evils already complained of in the case of voluntarily supported hospitals. Be this as it may, the occasion is one for asking whether the use of the infectious hospitals is to be universal and indiscriminate. If so, it is evident

that a far larger amount of accommodation than the present will be needed, for we are only at the beginning of this great experiment. A reluctance to enter hospitals was the prevailing feeling of all but those whose homes were destitute of proper convenience for the treatment of sickness. This had to be overcome, and it will be satisfactory to learn that it has not been seriously impaired by legislation. It may be that the 3823 patients now under treatment in the hospitals of the Asylums Board all come from the very houses which it is necessary to clear of such cases. We should be glad to know that this is the case. If, in consequence of the state of the law, no adequate information can be given of the fitness of cases, so much the worse for the law, and the sooner it is changed the better. What has to be feared is the creation, in classes that should be able to take care of themselves, of a feeling of dependence on the State in every emergency, together with a prodigious addition to taxation; for the demand upon the State will not stop at cases of scarlet fever, but will steadily extend to other complaints far more numerous and more costly. The facts before us at present are sufficiently significant—a wide prevalence of scarlet fever and the public provision for the accommodation of cases exhausted. The knowledge now supplied under the Notification of Infectious Diseases Act and the Public Health (London) Act goes to show that if we are to have no inquiry into the fitness of cases the present accommodation may have to be increased twofold or threefold to meet the demand which will arise when the old reluctance to use hospitals has been overcome.

THE Congress of the Sanitary Institute, which met the week before last at Portsmouth, has served the useful purpose of providing material for discussion on several subjects of general interest. The address of the President, Sir CHARLES CAMERON, contained an interesting account of the progress of sanitation during the Victorian era and showed the advance which had been made in improving the condition of the country, particularly as the result of the passing of the Public Health Acts of 1872 and 1875. But, while looking back on the triumphs of the past, the President did not neglect to point out that these gains had not been equally shared by all parts of the country, and much still remained to be done in those districts which had failed to avail themselves of the opportunities which the Legislature had given them. Sir CHARLES CAMERON dwelt upon the tendency of the people in England to become aggregated in large towns, as many as ten million and a half out of its twenty-five millions living under these conditions. It was therefore surprising that the population of England had a greater longevity than that of France, Germany, Russia, Italy and Spain.

In the sectional meetings a discussion of much importance followed the reading of a paper by Mr. OLDFIELD raising the question whether tuberculosis arises from eating the flesh of animals. The difficulties of attempting to show to what extent the flesh of the lower animals contributes to tuberculosis in man was made evident by the argument of Sir CHARLES CAMERON that the Irish poor, who eat very little meat, suffer greatly from phthisis; while the rich, who consume animal food largely, do not suffer to nearly the same

extent. It does not, however, follow that because certain causes of phthisis may be present in a population it is proper to neglect to take precautions in respect to other circumstances which may give rise to fatal disease. Evidence is undoubtedly accumulating to show that the eating of tuberculous matter, even after such cooking as ordinarily takes place, is attended with risk, and the question which has to be considered is whether the excision of tuberculous masses by the butcher in dressing the carcase is a sufficient precaution, or whether the flesh of a tuberculous animal, even when it is remote from the affected parts, is fit for human consumption. But other points than this have to be borne in mind; it may be that the condemnation of meat, which would result from the acceptance of the latter view, would lead to the deprivation of the poor of a food-supply which is absolutely necessary to them. There is evidently the greatest need of a better knowledge of the amount of risk which attaches to the use of the meat of tuberculous animals and the amount of prevalence of this disease among animals which are used for food.

This object was further considered in connexion with a paper by Dr. NEWSHOLME on Condemnation of Meat of Tuberculous Animals, and a resolution was adopted unanimously expressing the opinion that where a portion of an animal was affected by disease the whole carcase should be condemned as unfit for human food. Whatever view may be taken of this question no one will hesitate to endorse the opinion at which the Congress also arrived, that the abolition of private slaughter-houses in towns is an urgent necessity.

A paper on the Disposal of the Dead led to the expression of opinion of diverse sorts. Cremation was not without its adherents, although the arguments in its favour were based upon possibilities of infection being preserved in the earth which were not supported by any actual experiences of injury occurring from this cause. The difficulty of finding land suitable for the purposes of interment in the neighbourhood of towns was a more potent argument, and Dr. AXFORD cited the town of Portsmouth as an instance where this difficulty had been experienced. Advocates of cremation have the advantage of knowing that the growth of population must eventually increase this difficulty and lead to the more serious consideration of methods of disposal of the dead other than by interment. It may be gathered that the Congress did not regard the question as so sufficiently pressing as to necessitate any collective expression of opinion at the meeting.

A paper by Dr. DAWSON WILLIAMS afforded material for the discussion of the value of Quarantine in limiting the Diffusion of Cholera. Dr. LANE NOTTER properly asked what was being done in the smaller ports, and argued that the strength of our first chain of defence was measured by its weakest link. This is undoubtedly true, but it must be recollected that the complete exclusion of cholera from England is not anticipated. Persons suffering from or incubating this disease must necessarily find their way into different parts of the country, and it is therefore a matter of urgent necessity that every district should adopt those measures which it is now fully understood must be relied upon as the only certain means of protection against this disease. If one of the English ports should suffer severely from cholera as the result of local negligence, it obviously adds to the probabilities that cases of the disease will be introduced into

other localities; but even under these circumstances there is no occasion for alarm for those who are provided with an unpolluted water-supply and a system of removal of excremental refuse which prevents the contamination of earth, air and water. Dr. GROVES, in the course of the discussion, referred to the oft-made statement that cholera frequently polluted the course of rivers, and he cited the outbreak of 1866 in London as an instance of cholera spread by a contaminated water-supply. To those who have studied the behaviour of cholera in this country the association of cholera with rivers which serve for transit and for water-supply finds ready explanation.

Regarding the Congress as a whole, it may be stated that the subjects chosen for discussion were fairly practical, and sufficiently diverse in their character to enable all present to feel interest in the meetings. The opportunities thus afforded for exchanging opinions cannot fail to be valued by those upon whom devolves the duty of advising local authorities, and certainly the Congress at Portsmouth must have answered this purpose.

IDIOCRASY, according to the great English lexicographer, is "a peculiarity of constitution," and *idiosyncrasy* "a peculiar temper or disposition of body not common to another." The latter definition would have been even more complete had Dr. JOHNSON indicated that in the term "body" he included mind, for in the English language idiosyncrasy has been so used. Sir THOMAS BROWNE, with that charming self-satisfaction so characteristic of him, remarks: "I am of a constitution so general that it consorts and sympathises with all things. I have no antipathy, or rather idiosyncrasy, in diet, humour, air, anything. I wonder not at the French for their dishes of frogs, snails and toadstools, nor at Jews for locusts and grasshoppers; but, being amongst them, make them my common viands, and I find they agree with my stomach as well as theirs. .... I feel not in myself those common antipathies I can discover in others. .... I was born in the eighth climate, but seem to be framed and constellated for all." Before he has finished his idiosyncratic analysis even Sir THOMAS BROWNE, however, discovers he has a little weakness, but complacently justifies himself by declaring that he sins in good company. "If there be any among those common objects of hatred I do contemn and laugh at, it is that great enemy of reason, virtue and religion, the multitude; that humerous piece of monstrosity which, taken asunder, seem men and the reasonable creatures of GOD, but confused together make but one great beast, and a monstrosity more prodigious than Hydra." BULWER LYTTON remarks in his essay on the knight of Norwich that he never even mentions the great civil war in his writings, although much of his work was done during that period. We cannot, however, doubt, after the above confession of faith, that our distinguished *confrère* was a "good Cavalier"; and it is interesting to note that he even anticipated THOMAS CARLYLE in his comprehensive, though curt and not very flattering, estimate of the English people. It is in the wider sense in which Sir THOMAS BROWNE used the term "idiosyncrasy" that we purpose dealing briefly with the subject.

A French physician is said to have remarked: "In France we treat the disease; in England you treat the patient."

and as the general includes the particular we feel disposed to define idiosyncrasy simply and shortly as *the patient*. We believe the experience of practitioners generally will support the conviction that it is unfortunate for all concerned to allow the disease to obscure the patient in considering and treating his case. Had Sir THOMAS BROWNE'S private physician terminated an interview with his patient by singing the praises of universal suffrage he could scarcely have hoped to further the efficacy of his remedies. Our theme then is the patient. There are certain attributes which mankind possesses in common; for example, that mode of force called life and the apparatus which enables that force to act, in which is involved sex and age. But the endless variety which we find when we descend to particulars, such as occupation, climate and environment generally, are already present in the fundamental conditions. Variety and complexity in nature afford, however, no argument against the utility of fact-gathering and classification, and without these there can be no perception of principle or law and the rational conduct based upon obedience to the latter. It is therefore our duty to note details and conditions, physical and moral, in every instance, provided we believe them to exist—in fact, even when the bearing of such is by no means apparent to us. It is, moreover, sound instinct which, *ceteris paribus*, causes patients to prefer the advice of "one who knows their constitution"; that is, of one who has had special opportunities of observing their behaviour under diverse circumstances. Granted that there is a general knowledge of cause and effect as regards many physical and moral excitants, there is also a modified manifestation of these in almost every case. We know this to be true as regards articles of diet, and it influences our treatment of many digestive derangements. A choice of residence has in like manner and in many instances to be determined by the experience of the individual even more than by *a priori* considerations of probable fitness on the part of the physician. It is sufficient to refer to the apparent arbitrariness with which *locality* influences asthmatics who occasionally by accident, and for themselves, select a residence which frees them from long-standing distress. Even diseases which are regarded as having a typical course are modified in the persons of individuals, of families, and even of races. Such modifications may be theoretically explained by an assumed hereditary elimination or want of elimination of susceptibility, whatever that may be, in some such way as animals and human beings undergo a process of acclimatisation. But while we thus recognise effects we are in most cases very far from being certain of causes, and, but for the courage inspired by the grand triumphs of a patient science, are at times tempted, in a more or less hopeless mood, to echo the old cry,

"Felix qui potuit rerum cognoscere causas."

The experience of all must have furnished them with instances of unusual tolerance or of even more unusual intolerance of many drugs, such as opium, mercury, ipecacuanha, and the iodides. The action of the latter has been most interestingly dealt with by Mr. HUTCHINSON in his lectures on Temperament, Idiosyncrasy and Diathesis. In his remarks upon the action of the iodides and bromides he details the protean manifestations of the same agent in different individuals, and the serious and even fatal consequences of sometimes small and often moderate doses of these drugs form an

emphatic argument for that knowledge of *the patient* which we have indicated as so useful to the practitioner.

What is true of physical is true also of moral agencies. The difference (which physiologists have determined to exist in the rate of conduction of stimuli applied to the nervous system in different persons) reveals a difference in physical conditions too subtle for grosser demonstration, which probably lies at the bottom of idiosyncratic reaction, both to physical and moral stimuli. The discovery of differences in the effects of the latter is, however, more difficult than in the case of physical agents. While physiognomy (which LAVATER defined as "the science or knowledge of correspondence between the external man, the visible superficies, and the invisible contents") has not led to results of any great practical value, pathognomy, or "the knowledge of the signs of the passions," the evidences of the reaction of the individual to the ordinary wear and tear of human life, is not without value to the physician. Mere configuration or shape may be racial, and may present no easily associable counterpart in the inner man, or in that inner man of whom the world or even the individual is aware; but the manifestations of the "character in motion" are worthy of study, and may lead to fruitful conclusions. It is related of COLERIDGE that his poetic soul was harrowed by the want of correspondence between his outer and his inner man, but we suspect it was rather that his sense of the beautiful did not find entire satisfaction in contemplating his own visage, than that his countenance was devoid of the signs of his intrinsic nature. BULWER LYTTON has remarked with truth that "noble thoughts make noble faces," and SAMUEL TAYLOR COLERIDGE has given us many noble thoughts. The pathognomist in *him* may have been too exacting when he wrote—

"That outward forms, the loftiest, still receive  
Their finer influence from the world within,  
Fair ciphers of vague import, where the eye  
Traces no spot, in which the heart may read  
History and prophecy. . . ."

But the eye may likewise occasionally observe remarkable differences of behaviour in individuals under the sway of identical emotions. Thus one parent may grow visibly more grey during the illness of a child, while the hair of another of like age and equally fond may remain unchanged. What is true of so easily detected a change is true also of less readily detected changes in other tissues, such as skin and fat and muscle. While, moreover, these may be *diathetic* they are no less *idiosyncratic*, for the query, "Kannst du mich lehren von meiner Schatte zu springen?" must always be answered in the negative. Various as is the physiognomy of men there is an essential identity in their emotions. "One touch of nature makes the whole world kin," and community in feeling has its counterpart, though perhaps less evidently, in an essential similarity in the expressions of emotion. Moreover, the modern localisation of motor functions in the brain renders the observation of the expression of emotions, which may become stereotyped, important. The clue to pathognomic diagnosis lies probably within ourselves, as the above quotation from COLERIDGE suggests, provided due weight is given to the influence of easily ascertainable external circumstances, such as nurture, education and work, and the less easily ascertainable facts of personal experiences—circumstances and facts of which the physician should be fully cognisant to be fully useful. With such knowledge he may

estimate to a useful degree both the strain to which a patient has been subjected and the manner in which he has borne it. To few is it given to know, like Sir THOMAS BROWNE, under which "climate" they were born, and many are quite convinced that they were not "constellated for all," but a knowledge on the part of the physician of those agents and conditions which his patient as an individual tolerates best or resents most is of primary importance in the treatment of disease.

THE gradual diminution of cholera at Hamburg and in the north of France, together with the vigilant attitude of port sanitary authorities in England and Wales, tend week by week to improve our chances of escaping any diffusion of cholera this year. We may expect further importations of the disease and we must be prepared to deal with them, but we may with some confidence regard the risk of any cholera prevalence as transferred from this autumn to next spring and summer. Under these circumstances a review of that which has actually taken place during the month—Aug. 25th to Sept. 24th—will be historically interesting, and it will serve to show what are the lines of defence against cholera on which we have relied, and how preventive measures should be applied if we are to rely upon them in the future.

It was on Aug. 25th that the ss. *Gemma* arrived from Hamburg in the port of London with a detachment of Russian Jews and three cases of cholera on board. The three patients were removed to the port sanitary hospital below Gravesend, and, having regard to the extremely suspicious circumstances surrounding the remainder of the passengers, they and the vessel were detained afloat in the river, under observation, for several days; after which they were temporarily provided for in an encampment by the port authority. This later action went beyond the powers actually conferred under the Cholera Order of the Local Government Board then in existence, but the judicious action taken in this matter under the initiative and personal superintendence of Dr. COLLINGRIDGE, the port medical officer, received its justification a few days later, when an additional order was issued to meet the case of such passengers as these—that is to say, of persons whom it is impossible to keep under observation on arrival from an infected place or on an infected vessel, for the simple reason that they have no known home or destination. Dr. COLLINGRIDGE'S action at the time received full public support, and the special approval of the Local Government Board was communicated to him. All three patients died in the hospital and no extension of the disease took place.

Three further importations of cholera took place on Aug. 27th. In two instances the arrivals were at Grimsby; both patients were removed from the infected ship to the port hospital, where they were isolated until recovery, the ship being detained at the mooring ground for purposes of disinfection. The third case was an arrival by ship at Middlesbrough. In this case the sick man was also removed to the port hospital, but he died on the same day. Liverpool was next found to be the seat of imported cholera, for on Aug. 28th four Russo-Jewish emigrants, who had crossed England and got as far as that port, sickened with the disease. They had reached Liverpool by land, and hence they were removed, not to the port hospital on the Cheshire side of the Mersey, but to one of the three isolation

hospitals possessed by the corporation as sanitary authority for the city. Two of the patients died and two recovered. Their previous movements were ascertained and every precaution, by way of cleansing and disinfection of their temporary habitation, clothing &c., was taken, and those with whom they had associated were watched for some days; in order to see if any spread or infection had taken place. Happily no such diffusion had occurred. On the same day a German, recently arrived from Hamburg, was found to be suffering from cholera in London. He was removed to the Royal Free Hospital, where he made a good recovery. On Aug. 29th a case of cholera was imported by a vessel into the port of North Shields. This patient was at once isolated in the sanitary hospital, the ordinary preventive measures were adopted and the disease was checked. On Aug. 30th a further case was imported into Grimsby; it was dealt with in the same way as the former was and with a like result. On the same day three patients were removed to St. Bartholomew's Hospital. They had arrived at Harwich by boat from Hamburg, were in apparent health on arrival, and were consequently allowed to land. But soon after reaching the metropolis two of them were found by Mr. HARRIS, medical officer of health of Islington, to be suffering from cholera, whilst the third had diarrhoea. In the end the last case turned out not to be one of cholera, but of the other two patients who were suffering from the disease, one died on Aug. 31st. On Aug. 30th a further case occurred in the port of Grimsby, but the spread of the disease was again checked by isolation and disinfection and the patient recovered. Three cases were also found in the port of Falmouth on the same day. They had arrived by ship from Hamburg, were removed to the port sanitary hospital and recovered. Here, again, measures of disinfection were adopted and suspected members of the crews were kept under observation.

After an interval of four days a case was imported into Tynemouth, the vessel bringing the patient again hailing from Hamburg. This patient was removed at once to the sanitary hospital, where he died next day. On Sept. 5th a fifth case occurred at Grimsby, the patient being, as on former occasions, a recent arrival from Hamburg. This patient died on Sept. 11th in the port hospital. Next day, Sept. 6th, a patient was brought into Blyth by a Hamburg vessel; the patient was isolated and he recovered. Then an interval of ten days elapsed, during which only a few rumours of cases, which turned out not to be cholera, occurred. But on the 16th another case reached the port of London. This case was detained off Gravesend by Dr. COLLINGRIDGE on board the ship in which the man had arrived from Antwerp, and after his recovery the vessel was allowed to proceed up the river. Three days later—namely, on Sept. 19th—a case was imported into Hull from Hamburg. The patient was removed to the port sanitary hospital, where he died; the vessel was sent to the mooring ground for cleansing and disinfection and all needed precautions were adopted. On the same day a vessel arriving from Rotterdam at Harwich brought another cholera case into a fresh port, but the patient was isolated in the port authority's hospital and no further mischief ensued. After another lull a second case reached Hull from Hamburg on Sept. 24th. The man was removed to the hospital, the usual precautions were taken and the patient recovered. Lastly, a doubtful case occurred at Bridgwater. The patient, one of the crew

of a vessel which entered the dock at Sutton Bridge, was on his way to Plymouth on the 26th when he was suddenly seized with symptoms very characteristic of cholera. The vessel came from near Archangel, Russia, and had only touched at Bergen, whence no cholera has been reported. Hence the case must for the moment remain undetermined.

But, excluding this case, it is satisfactory to note that during the month in which cholera has been making its way into our ports twenty-six cases have reached us, and in no instance has the disease spread beyond the actual individuals arriving from abroad. Precisely the same remark applies to two cases at Glasgow and two cases at Grangemouth in the Firth of Forth.

## Annotations.

"Ne quid nimis."

### THE LOCAL GOVERNMENT BOARD AND THE ROYAL COLLEGE OF PHYSICIANS.

THERE can be no doubt that the correspondence between Sir Hugh Owen, the Secretary of the Local Government Board, and the President of the Royal College of Physicians has led to some misapprehension as to the scope of the instructions asked from the latter body. In Sir Hugh Owen's letter it is stated without limitation that the local sanitary authorities are required to "provide and to dispense without charge medicines and medical appliances for the sick," but a correspondent points out in another column that Section 133 of the Public Health Act empowers the local authority to provide, or to contract with any person to provide, a *temporary* supply of medicine and medical assistance for the *poorer inhabitants of the district*. If this limit had been appreciated by the Royal College of Physicians that body would hardly have taken upon itself to publish general instructions for the management of health in view of the prevalence of diarrhoea and of cholera, and appear to supersede the medical advisers of the Local Government Board, on whom rests the duty of framing and carrying out the regulations which are deemed necessary for the prevention of these diseases. The medicines best adapted to the immediate medical treatment of patients suffering from the disease would have then been the only consideration for the Fellows of the College. The College wisely declines to give instructions for the treatment of cholera. "Every case of this disease requires separate consideration and management; no stereotyped plan of treatment would prove to be either wise or safe, and usually before the choleraic nature of an attack could be established medical assistance would have been procured." But the details concerning the management of looseness of the bowels go much beyond the former recommendation of ten grains of aromatic powder of chalk and opium or five minims of laudanum. It is scarcely hypercritical, we think, to remark that the treatment in its entirety would be somewhat difficult to carry out in the houses or rooms of the "poorer inhabitants," and would necessitate skilled nursing and medical attendance.

### STREET DUST, WOOD PAVEMENTS AND CHOLERA.

A SERIOUS accusation has been brought against one of the most popular of many conveniences enjoyed by the modern townsman. The sanitary condition of wood pavement has been called in question, and that with special reference to its influence as a possible nidus for the cholera germ. Placed as we are in the near neighbourhood of ports infected

by that disease, we would be the last to discourage any rational sanitary precaution, however trivial it might appear to be. We fully recognise the importance of maintaining at all times as perfect cleanliness as possible on the street as well as in the household; at the same time, we cannot ignore the strenuous and successful efforts put forth in this direction by local vestries and municipal councils, neither can we regard as inevitable the suggested connexion between the dust of wooden or other pavements and the spread of cholera. No such connexion has hitherto been proved in respect of other epidemic diseases which from time to time have prevailed in our cities. Furthermore, we must remember that the development of a given infectious malady requires the initial contact of its particular virus or germ. Now it is, on the whole, a happy circumstance that most of this morbid matter finds its way underground by way of the domestic drain pipe. Infection of street refuse is by no means impossible, but this, in by far its greater proportion, consists only of mud, manure and particles of old wood. Doubtless its purification is always desirable. It is also comparatively feasible if, as often happens, the streets be freely washed with disinfectant fluids. We would advise the vigilant observance of every such method. We confess, however, that in so doing we are instigated less by the dread of a special contagion than by a regard for the permanent advantages of general cleanliness.

### SEA-SICKNESS.

MOST of those who have experienced the miseries of sea-sickness, however they might differ in minor details of statement, would agree in ascribing this most dispiriting malady to one main cause—the motion of the ship. In so far the whole medical faculty would concur in their decision. This, then, is the central fact which confers upon the disorder its unique position. It is really not a pathological but a physiological disturbance. It has no natural connexion with dyspepsia. The robust and healthy, by a strange contradiction, suffer from it for the time hardly less than the weak and ill. Its variations of intensity are felt to be counterparts of mere bodily oscillation. Some find relief from it in change of posture, others in active occupation, all more or less when their storm-tossed vessel sails under the lee of land. Custom and use commonly secure immunity. These are circumstances which one and all point to mechanical causation as the source of the discomfort. It is the unaccustomed rise and fall, the jerk and relaxation of loosely attached abdominal viscera, mainly, perhaps, but not alone, of the stomach, acting upon the central nervous connexions, which must bear the brunt of accusation. It follows that successful treatment cannot be guaranteed by any one method or panacea. Recumbency, pure deck air, moderately firm bandaging of the body are all useful. Drugs have their place and their partial utility; but, as we have already suggested, there is no remedy equal to a lee shore. Nothing can be much more depressing than sea-sickness, and for this reason we should strongly advise all weak persons not to encounter, if possible, the risk of its occurrence. It is astonishing how soon and how completely those who are favoured with a fair measure of constitutional elasticity recover from its depression. In their case the benefits of a sea trip may thus, with compensations of air, diet, and appetite, be even enhanced by a few hours of mechanical nausea. It is, in truth, for such persons only that tours of this kind are advisable.

### THE WINTER SESSION, 1892-93.

THE winter session of the medical schools throughout England was inaugurated by the opening of Mason College, Birmingham, on the 30th ult., with an address by Sir George M. Humphry. To-day (Oct. 1st) Dr. Bowles addresses the students at St. George's Hospital, the same date witnessing the opening of King's College and the University of Durham.

Most of the schools will commence on Oct. 3rd and many will inaugurate their opening by a dinner. The Middlesex, University College, Westminster, King's College, the London and St. Thomas's Hospitals will all begin their sessions in this way. Dr. J. J. Pringle and Mr. S. J. Hutchinson will lecture at the Middlesex and University College Schools respectively, whilst Guy's Hospital will open with an address by Mr. A. Ernest Maylard, on the subject of "How to remain a Student through Life." Dr. Mercier will preside at the opening of the Westminster School of Medicine, and at St. Mary's Dr. A. P. Luff will address the students. At the Royal Veterinary College the address will be delivered by Professor McFadyean. St. Bartholomew's, Charing-cross and the Dental Hospitals do not open with any formal address, and their example is followed by the University of Durham. In Owens College, Manchester, the address will be given by Dr. W. H. Broadbent; whilst at Yorkshire College, Leeds, and Firth College, Sheffield, the students will listen to Professor W. Mitchell Banks and Dr. Burges respectively. The College of State Medicine will open on Oct. 5th with an address by Surgeon-General W. Robert Cornish, and on the same day the Pharmaceutical Society will celebrate its fifty-first session and its jubilee with an address by the President.

#### THE BOURNEMOUTH IMPROVEMENT ACT, 1892.

WE have before us a memorandum by Mr. Philip W. Nunn, medical officer of health for Bournemouth, directing our attention to some of the more important alterations in the sanitary laws effected by the Improvement Act of 1892, and we quite agree with Mr. Nunn that Bournemouth is to be congratulated upon the additional powers which have thus been conferred upon its sanitary authority. In many important particulars this Act is an extension of the Public Health Act of 1875. Thus we are informed that by Section 2 power is granted to the local authority to check the spread of infectious disease through defective milk-supply. Although we are not told how this is to be carried out we presume the powers now vested in the Bournemouth local authority are similar to those enjoyed by sanitary authorities in the metropolis under the Public Health (London) Act, 1891, by which the medical officer of health, upon obtaining an order from a justice having jurisdiction in his district, is enabled to inspect dairies, and, if accompanied by a veterinary inspector, the animals also; and, if satisfied that the milk supplied from the dairy has been the cause of infectious disease, to report thereon to the sanitary authority with the view of prohibiting the further sale of the infected product. By Sections 7 and 8 "the corporation may, if they think fit, from time to time provide, or contract with any person to provide, nurses for attendance on any person suffering from infectious disease within the borough, and may charge a reasonable sum for the service of any nurse so provided." No doubt the provision of nurses by the corporation may, under certain circumstances, be highly advantageous; but as we are informed that this clause aims at the arrest of infectious disease, doubtless the sanitary authority will also bring into action with their nurses a system of efficient isolation in the treatment of such cases. By Section 9 persons owning laundries are required to furnish lists of the owners of clothes. This is a most important step in advance, as it puts into the hands of the sanitary authority the power to check the spread of infectious disease through the easiest and widest of all channels. We are strongly of opinion that in those cases where the sanitary authority do not themselves disinfect clothes, bedding &c. the thorough disinfection of all such articles by the patient's friends should be insisted on before removal to a laundry. Section 13 is an extension of Section 124 of the Public

Health Act, 1875, the local authority being now empowered to regard any person as having insufficient lodging accommodation and to remove him if in their opinion there is a danger of his spreading infection to other persons in the same house. By Sections 15 and 17 power is granted to the sanitary authority to deal with the drainage of houses built before the passing of the Public Health Act and other Acts. By these sections drains and waste pipes are required to be disconnected from the sewer; and the local authority is permitted to apply the smoke test for the purpose of ascertaining whether the house drain is watertight. We notice that Bournemouth has had in operation for the past fifteen years a system of voluntary registration of houses with the local authority, and that the majority of houses in the town, having conformed to the requirements of the sanitary authority, have been placed upon their register. The large measure of success that has attended voluntary registration will therefore greatly diminish the labours of the corporation in compelling those landlords who have not chosen to accept their invitation heretofore to put their houses at once into thorough sanitary repair. Section 31 enacts that a badly constructed or ill-kept cistern shall be deemed to be a nuisance. By Section 72 slaughtering is prohibited except in corporation abattoirs, when so provided. This is a most salutary regulation, for it may be confidently expected that it will not only ensure perfect cleanliness in the slaughterhouses themselves, and a minimum of annoyance to the public, but, what is far more important, will enable a thorough inspection of meat to be made before being exposed for sale. The corporation of Bournemouth by securing these additional powers have immensely strengthened their sanitary code of by-laws, and we see in the new Act an earnest desire on the part of the sanitary authority to ensure for their town the highest standard of healthiness.

#### THE ABDUCTOR AND ADDUCTOR FIBRES OF THE RECURRENT LARYNGEAL NERVE.

THE results of an experimental investigation into the functions of the recurrent laryngeal nerve were recently communicated to the Royal Society by Dr. Risien Russell. The investigation was undertaken with the view of discovering whether it was possible to separate the adductor fibres from the abductor fibres of this nerve. It has been long recognised that in organic and progressive affections of the nerve the abductor fibres are likely to suffer sooner than the adductor fibres, but the reason of this is not at all clear. It was suggested by Sir Morell Mackenzie that possibly the abductor fibres were more superficially situated than the adductor, and that this would account for their earlier affection in cases of tumour and of pressure generally from outside. Dr. Risien Russell's experiments were carried out on dogs, the individual bundles of which the nerves were composed being separated and stimulated electrically. The relative irritability of the different bundles was also observed and the bundles were traced by dissection to their peripheral distribution. The abductor and adductor muscles were also subjected to direct observation when excited to action after dissection, and experiments and observations were made on the degenerations following the division of different bundles of nerve fibres. The results of these different investigations show that the abductor and adductor fibres in the recurrent laryngeal nerve are collected into several separate bundles, each preserving an independent course throughout the nerve trunk to its termination in the muscle or muscles which it supplies. It was also found that whereas in the adult animal simultaneous excitation of all the nerve fibres in the recurrent laryngeal nerve results in adduction of the vocal cord on the same side, in the young animal the opposite effect—viz., abduction—is

that produced by an exactly similar procedure. When the abductor and adductor fibres are exposed to the air the abductor nerves are found to lose their power of electrical excitability much sooner than the adductors, and this is true of both young and adult animals, although in the former the abductor fibres retain their excitability longer. It was, further, found possible to separate the adductor fibres from the abductor through the whole length of the recurrent laryngeal nerve to their termination in the muscles, and also to so accurately separate the two sets of fibres as to be able to produce abduction or adduction, as the case might be, without evoking any contraction in the muscles of opposite function. The complete separation of the two functions was also shown by the degeneration of the muscles related to one function which followed the division of the corresponding nerve fibres, while the muscles subserving the other function remained unaffected. The greater liability of the abductor fibres to degeneration is very curious, and no explanation of the phenomenon is forthcoming. Sir M. Mackenzie's theory does not find any support from the investigation under discussion—in fact, it is held to be disproved. The fact that in the young dog the abductor influence is found to predominate makes an explanation even more difficult, unless Dr. R. Russell's view is accepted that the greater power of adduction in the adult is related to the increased power of phonation, while in the young animal phonation is imperfectly developed.

#### RESPONSIBILITY FOR MEDICAL FEES.

AT St. Helen's a claim has been recently tried of some interest to the profession. It is reported as follows in the *Liverpool Mercury*:—"Dr. Twyford, Dr. Reid, and Dr. Masson sued Henry Stansfield, landlord of the New Market Inn, Naylor-street, St. Helens, for £11 2s. 6d. for medical attendance on his niece, Miss Caine, who was accidentally burned while working for him in his house. The plaintiffs founded their claim on the fact that when the girl was injured Mr. Stansfield sent for Dr. Masson, who after the first day sent a note to Mr. Stansfield's place by a boy asking if he should still continue to attend, as he was not the family doctor, and got a reply that he was to attend. Mr. Riley, for the defence, urged that the girl was an adult, and presumably could enter into a contract for herself. When the boy came from Dr. Masson with the note it was the girl's mother who answered and not Mr. Stansfield. His Honour said the only evidence against Mr. Stansfield was that he went for the doctor, and they surely were not going to make everybody liable who went for a doctor. As Miss Caine had since married her husband had offered to pay one-half if Mr. Stansfield would pay the other, and the judge entered a verdict against him for £5 11s. 3d., with costs." We think Mr. Stansfield has got off very easily and may congratulate himself. The judge's verdict is better than his logic. Surely when the landlord of an inn sends for a medical man to attend a patient suffering from burn contracted in his house, without disclaiming responsibility, he should be held to be liable.

#### DANGERS OF THE STREETS.

It is clear that in most cases in which one's personal safety is imperilled by so-called accident the responsibility for its preservation has a double significance. It has a positive and a negative relation. It implies protection against the culpable negligence of others and it also entails obedience to the caveat of a rational self-concern. Innumerable circumstances of daily life might provide us with illustrations of our meaning, but for the present we are content with one only. We have spoken in former issues of the dangers underfoot which threaten the security of passers-by in every thoroughfare. Trap-doors, coal-cellar plates and other occasions of injury have been repeatedly discussed. Telegraph and telephone

wires have likewise been considered. We would now notice another source of danger overhead, in the chain which hangs laden with heavy goods from the arm of a crane in front of so many warehouses. It is, indeed, surprising to note how seldom accidents happen in the working of this convenient and simple apparatus and with what accuracy the binding rope, swiftly and loosely cast about its burden, tightens at the moment of ascent. Notwithstanding, there is no absolute security—far from it—and accidents do happen. Now and then comes a slip and the load falls. The possible risk to *employés* and to casual wayfarers requires no explanatory comment. That incurred by the former is largely their own concern, though this does not of course condone the carelessness of fellow-workmen. The case of ordinary foot-passengers is different. The demand upon their personal caution is less and their title to the fullest external guarantees of safety cannot be denied. We take it, therefore, to be unquestionable that any warehouseman in loading or unloading over the public street must warn off all passers-by from the scene of his operations. A red flag of sufficient size might serve as the usual signal of danger, but surrounding the point of temporary obstruction with a rope barrier would still better secure the end in view.

#### THE TREATMENT OF TETANUS.

IN the *Therapeutic Gazette* of February, March and April Dr. Braden Kyle gives the results of a series of experiments made on the pathology and treatment of tetanus, in which he concludes that the bacillus of tetanus is an obligate anaerobe, and that its virulence is actually diminished when the organism is deprived of oxygen; that the bacillus grows best at a temperature of 98° F., but that it will grow rapidly when the temperature is as low as 51°. Pure cultures when inoculated induced fatal results in less than 50 per cent. of the cases, and from inoculated animals that died Dr. Kyle was unable to produce tetanus in other animals. In some cases the bacillus was found at the point of inoculation. He considers that the organism is polymorphous; that it is extremely resistant to the action of heat, corrosive sublimate, peroxide of hydrogen and carbolic acid, but that it is extremely sensitive to hydrochlorate of cocaine and to the fumes of bromine. He concludes that the treatment of cases of tetanus may be summed up as follows: "(1) Disinfection of the nidus of development of the bacilli; (2) the elimination of the poisonous products of the bacilli from the system; (3) drugs which are sedatives to the nervous system; (4) excision of the cicatrix."

#### AN APPARATUS FOR COLLECTING WATER FOR ANALYSIS.

IN collecting water for bacteriological investigation it is often an extremely difficult matter to obtain a number of satisfactory samples, especially from some distance below the surface, without a very great amount of what seems to be unnecessary trouble. In the *Canadian Record of Science*, January, 1892, Dr. Wyatt Johnston of Montreal describes and figures an apparatus for this purpose. This consists of a kind of weighted frame in which a sterilised bottle is placed; the neck of the bottle is grasped by a clamp, and the stopper, which is in the form of a tapering glass rod, is grasped by another clamp and is kept in position by means of a spring. Attached to the clamp holding the stopper is a cord, and the frame is suspended by another cord. When a sample of water is to be taken, a sterilised bottle with its stopper still in position is put into the frame; the whole is then sunk to the required depth, just as is a sounding lead; then the string attached to the stopper clamp is pulled, the bottle fills in from twenty to thirty seconds; the clamp string is allowed to relapse; the springs bring the stopper back into position and the apparatus is withdrawn. The bottles re-

commended are the ordinary drop bottles fitted with ground glass pipettes, the two ends of which are sealed in a gas flame, thus converting them practically into glass rods. The apparatus can be used from a boat, from a bridge, or from the shore. Dr. Johnston also makes a very good suggestion—that instead of using Petruschky's flattened flask, the ordinary flat-sided, common white glass phial plugged with cotton wool and wrapped round the end of a wooden tooth-pick may be used. Such bottles are readily obtained, and the disadvantage is that the glass is somewhat thick, so that it is sometimes necessary to use a correcting lens. They pack well and are invaluable for field work.

#### NATIONAL SOCIETY FOR THE EMPLOYMENT OF EPILEPTICS.

WE have frequently called attention to the unfortunate condition to which many epileptics, and often their friends, are reduced in consequence of their disease, and it was only recently that we alluded to the opening of Lady Meath's Home of Comfort for Epileptics at Godalming—a most laudable attempt to alleviate some of the miseries which are attendant on epilepsy and similar disorders. From a document before us we now learn that a society under the above name has been formed to provide a home for necessitous epileptics who are able and willing to work, but who are unable to obtain employment on account of their affliction. It is intended to have a series of cottages, each accommodating ten to twenty epileptics. The sexes will be separated and adults and children will also be kept apart. Market gardening, spade and barrow labour, will be the first industries, and as the colony extends other trades and mechanical arts will develop. In this way it is hoped that the institution will be, to a certain extent at least, self-supporting. It will be under medical supervision and entirely undenominational, and while in the first instance intended for the poor, its advantages will also be extended to patients possessed of means, who will be received as boarders. The institution is intended to be conducted on lines similar to those on which the Bielefeld Epileptic Colony has been so successfully organised, and a beginning is to be made with a few male patients. Only money is needed to allow a fair start to be made, and this, it is hoped, will soon be forthcoming. An influential executive committee has already been formed and many have intimated their willingness to support the scheme. The honorary secretary is Miss Burdon-Sanderson, Branksome, Greenhill-road, N.W., and the honorary treasurer Mr. H. N. Hamilton Hoare, 37, Fleet-street, E.C.

#### BACTERIA IN WOUNDS.

PROFESSOR WELCH and his pupils have for some time been doing very good work in connexion with the study of the micro-organisms found in wounds. In the April number of the *Johns Hopkins Hospital Bulletin* Drs. Hunter Robb and Albert A. Ghrisky publish an interesting contribution on the Bacteria in Wounds and Skin-stitches. These wounds were all in the abdomen or in the peritoneum. In order that as few errors as possible might creep in they adopted the most rigorous antiseptic precautions, carefully soaking the skin with a 1 in 5000 aqueous solution of bichloride of mercury before the operation, cleansing the part with warm distilled water and oleine soap, then washing with absolute alcohol, then with a warm saturated solution of permanganate of potash, followed by a warm saturated solution of oxalic acid, warm sterilised saline solution, Squibb's ether to remove fatty matter, a 1 in 1000 warm aqueous solution of bichloride of mercury, and finally giving a thorough washing with sterilised salt solution. In all cases the peritoneum is brought together by a continuous catgut suture, in order to prevent the infection of the abdomen by means of the skin-stitches. The skin and

muscular surfaces are brought together by deep silkworm gut and superficial silk sutures, and the wound is covered with a mercurialised solution of celloidin, 1 in 30,000. A piece of sterilised gauze is then placed over the incision, just enough to cover it. This is saturated with mercurialised celloidin, and sprinkled with iodoform and boric acid, 1 in 7. "Over this a piece of gauze, large enough to protect the incision on all sides, is applied, and covered with the mercurialised celloidin, and the iodoform and boric acid are again used. Finally, several layers of sterilised absorbent cotton are applied and then the scultetus, or many tailed bandage, is adjusted." Drs. Robb and Ghrisky conclude that under these conditions silkworm gut or silver wire sutures contain fewer germs or organisms than catgut, the knot of catgut sutures being specially rich in organisms, consisting almost entirely of a mass of bacteria. Silver wire sutures contain numerous bacteria, but a smaller number than catgut. Silkworm gut is the most resistant and harmless material that they have yet used; it acts as a kind of splint and is very readily sterilised. In forty-five cases examined the superficial stitches contained staphylococcus epidermidis albus in thirty-three; in five of the others staphylococcus pyogenes aureus was also found; in one staphylococcus gilvus only; in two staphylococcus gilvus and albus; in one streptococcus pyogenes with staphylococcus epidermidis albus; and in three streptococcus pyogenes only.

#### THE MICROBE AND EARLY MEDICAL LORE.

IT is curious to observe how from time to time different people lay claim for their own special school or their own country to the discovery of a bacteriological etiology of disease. The recent Oriental Congress calls to mind Pandit Janardhan's article on "Disease Microbes anticipated in Sanskrit Medical Works," which appeared in the April number of the *Imperial and Asiatic Quarterly Review*. It must be confessed that he does not bring forward anything to prove that naked-eye parasites were the cause of disease, and his illustrations in support of his theory that Indian sages looked upon organic germs as the cause of disease scarcely warrant the interpretations he puts upon them. He depicts the ordinary forms found on many of the older manuscripts and tablets: snakes, scorpions (or something like them), pediculi, star-fish, tadpoles, and curiously enough—as if the draughtsman had had some quaint conceit in his mind—outlines of manikins such as most of us have drawn on our slates during the earlier period of our lives. The article is exceedingly interesting, but we must, throughout, read "worms" or "animal parasites" for microbes, for of the presence of the microbe in the mind's eye of the earlier medical sage there is little or no evidence.

#### EPILEPSY AND EPILEPTIFORM TIC.

WHOEVER has seen a severe and typical case of facial neuralgia must have recognised the appropriateness of the term, *névralgie épileptiforme*, which Trousseau applied to it. The term was apparently used because of the analogy which the condition offered to epilepsy in the nature of its onset and duration, and not because of any supposed etiological connexion. But, as M. Fôré points out in his interesting paper on this subject in a recent number of the *Revue de Médecine*, Trousseau was not unaware of the occasional occurrence of both conditions in the same patient, and he states some facts which had led him to believe that in certain cases epileptiform neuralgia was one of the manifestations of true epilepsy. He instanced the case of a provincial *confrère* whom he had treated for some years for severe facial neuralgia and who had, towards the end of his life, epileptic fits; and that of an American who had

for two or three years suffered from severe attacks of tic with typical attacks of epilepsy. But on the whole he was apparently inclined to think that such occurrences were coincidences, and that the two conditions showed striking differences in the absence of heredity and of mental obscurity in cases of facial neuralgia, and the want of synchronism in the onset of the diseases. But as M. Féré points out, a number of the slighter signs of epilepsy are often present before the typical attacks come on, and in many cases no proof of heredity can be furnished. Further, too much importance, he thinks, may be attached to the absence of mental obscurity, for even in epilepsy such a condition can sometimes only be shown to be present by time measurement, and as pain lengthens the time of reaction a similar condition may be suspected to be present in severe neuralgia. But M. Féré brings forward a fact even more suggestive of a close connexion between the two conditions—viz., the occurrence of epilepsy and epileptiform neuralgia in the same patient, and the disappearance of both conditions under treatment by bromide of potassium. The case is one which had been under his own observation, and, in reference to this particular point, is very interesting.

#### A BACTERIOLOGIST FOR NEW YORK.

THE Board of Health of the City of New York has, the *New York Medical Journal* states, taken a step that is worthy not only of commendation, but also of imitation by other municipal boards of health. Heretofore the disinfecting corps has consisted of sixteen laymen. This division has been reorganised and is now denominated the division of pathology, bacteriology and disinfection. The chief of the division is to be an expert bacteriologist, and he will have ten physicians under his direction as disinfectors, each of whom has a certain district to supervise. The salary of the bacteriologist in chief is 3000 dols. (£600) per annum, and Professor Herman Biggs, who has been in charge of the Carnegie Laboratory for many years, has been appointed chief of the division.

#### FEVER IN LONDON.

THE pressure on the beds in the Asylums Board hospitals still continues, and we hear of patients sitting on the doorstep at Norfolk House until the ambulance can fetch them away. The scarlet fever accommodation is reported to be exhausted to all intents and purposes, for only some five beds are vacant, and those only for convalescents at Winchmore Hill. In the meantime, the new hospital at Tottenham is being pressed on to completion and it is expected to be ready in about a week's time. This will give the Managers some four or five hundred more beds and will, it is hoped, enable them to tide over the difficulty. There will be some temptation to overcrowd this new hospital, but we trust that the interests of the patients themselves will be considered in this connexion and so undesirable a proceeding avoided. At the meeting of the Asylums Board on Sept. 17th the chairman made an attack upon the Local Government Board, blaming the superior authority for the delay that had occurred in the erection of this proposed hospital and for the general delay in meeting the pressure which existed. Pending any reply from the Local Government Board, it should, however, be remembered that that body is not an initiating or executive authority, but simply a supervising or controlling arm of the State. It is the Managers who have these functions assigned to them, and it is for them to mature in times, when no pressure threatens, those measures of hospital isolation and equipment that may appear necessary in the future. Then it should be recollected that the higher board has other duties to the public besides that of granting assent to the Asylums Board for their doings. In the case of the proposed Tottenham Hospital there was considerable local opposition amongst the

residents to its erection, and the Local Government Board was obliged to institute a careful local inquiry before granting its assent. Some delay must therefore have been unavoidable, for which that Board can hardly be held responsible. The large proportions of the present prevalence can hardly be credited with the appellation of a serious epidemic; for the excess over the autumnal incidence of other years is more apparent than real, and due most probably to (1) notification and (2) a greater willingness of better class people to avail themselves of the hospitals (with this feature we have dealt fully in a leading article). In any case, the Managers have an urgent duty before them in grappling with this problem of fever hospital accommodation in London; and we trust that no time will be lost in gradually providing an adequate number of beds for its growing population, taking as a basis the recognised official datum of 1 bed per 1000 inhabitants.

#### CARRIAGE LIGHTING ON THE UNDERGROUND RAILWAYS.

TRAVELLERS by the Underground Railways are for obvious reasons peculiarly dependent upon the efficient management of carriage lighting arrangements. The time spent by them on their subterranean journeys is considerable. To those who are daily engaged in business in the City the period of tunnel transit each morning and evening would be wearisome indeed but for the page of news; and this again would be a tantalising luxury without sufficient light for its perusal. It is therefore particularly to be regretted that this much-needed convenience is not always adequate to its intended purpose. By way of justification we are told that in order to provide the gas pressure required for better illumination a much larger outlay than is now allowed would be called for. It is also pointed out that occasionally small electric lights may be obtained for the trifling sum of a penny. Here certainly is a grain of comfort, and a cheap one enough. To our mind, however, the question cannot be thus easily disposed of. Sufficient light is a primary necessity, and should therefore be provided at the cost of the railway companies, and should therefore be provided at the cost of the railway companies. We might suggest several alternative methods for securing this result. A possible augmentation of gas pressure has already been mentioned. An increase in the number of gas jets—at present two to each first-class compartment—would fulfil the same purpose, though it would also, of course, involve a greater expenditure of gas. Something might likewise be done by increasing the power and ensuring the cleanness and brilliancy of reflectors. Whatever the method employed, however, the responsibility for adequate illumination, we repeat, should certainly devolve upon the company. Light is not to be doled out at an extra charge through an automatic penny slot.

#### THE DIAGNOSIS OF HÆMORRHAGIC SMALL-POX.

OUR correspondent in the Northern Counties stated in THE LANCET of Sept. 17th, that Dr. Armstrong had informed his local authority that a case of small-pox sent from North Shields to the infirmary at Newcastle had not been diagnosed as such at North Shields, and that it was a case which nineteen doctors out of twenty might not have recognised as small-pox. We think Dr. Armstrong has been rather harshly criticised, and we do not wonder that the local authority has unanimously refused to admit the correctness of Dr. Whamond's charge that he had magnified his own powers of diagnosis as against those of 95 per cent. of medical men. Dr. Armstrong is a busy medical officer of health, and for some weeks past has doubtless been subjected to a strain of official duties in connexion with cholera which is itself an excuse for not having chosen words beyond all ambiguity of meaning. But even as his words showed, "it was a case which nineteen doctors in twenty might not have recognised as small-pox." They would seem to imply no censorious reflection on any

medical man, but only that the case was an exceptional and irregular one, in which diagnosis was far from easy. Van Swieten says: "Physicians who are conversant in practice will, I believe, freely acknowledge that it is not an easy matter to distinguish the small-pox *at first* from any other acute inflammatory disease. They will therefore be cautious how they pronounce upon that head *at first sight*." This is the expression of the largest experience and profound common sense. The man who comes second—and even a few hours make a difference in these rapidly fatal cases—has an advantage over the man who comes first. Even when the disease is epidemic and practitioners are on the look out for it, and when the course of it is regular, it cannot be diagnosed *at once*. But in the hæmorrhagic form the eruption may not be forthcoming at all, and if nothing is known of the history of the patient and his exposure to infection, it is a case not to be pronounced on dogmatically at first sight. Small-pox has of late years been in such complete abeyance that we are apt to forget its existence and especially its malignant aspects. The Tyne case should have the good effect of putting us all on our guard.

#### SHORTENING THE ROUND LIGAMENTS.

DR. CHALOT of Toulouse employs a modification of Alexander's method of shortening the round ligaments of the uterus in cases of painful retroflexion. He opens up nearly the whole of the inguinal canal, which enables him to reach the entire thickness of the round ligament even in stout subjects; each ligament is then dissected up to the internal ring, or even into the peritoneal cavity. The replacement of the uterus is not obtained by the support of an assistant, but by direct traction on the two ligaments, each of which is then stitched to the walls of the canal along its entire length. No pessary is used after the operation. The results of this method have given Dr. Chalot great satisfaction.

#### "WHY WEAR A HAT?"

PERHAPS no article of clothing has been more freely criticised in respect of its utility than that which lexicographers describe as a "covering for the head." Some, instructed by the example of savage races and of others widely different in various ways, among them the leaders of feminine fashion, whose crowns of gossamer may practically be disregarded, would have it that the hatless condition is that most characteristic of mankind. Against their opinion we find arrayed the combined force of civilised usage in every climate. From pole to pole we find that man, if he dresses at all, dresses his head. Even if bootless and guiltless of such minor trifles as waistcoat and collar, he covers the head with some form of clothing. Nay, the very savage, though he may know nothing of silk or felt, will often so decorate his vertex with feathers, or so weave its own natural wool, that not even the conventional European cylinder could protect it more effectually. Surely there must be reason in all this. There is a clearly conscious need which exists not merely in the imagination. It is thus practically admitted that though the head, like any other part of the body, may, after having suffered the attrition of atmospheric variations, become injured to their action, it still loses somewhat in the process. In the first place, it is evident that in this conflict only the fittest can hope to survive. Civilised man will not endanger his chance of survival by risking the experiment. Further, he finds that the inferior animals thus exposed undergo external changes which do not often, if ever, tend in the direction of refinement, and instinctively he shuns the possible return to coarseness and barbarism. He also recognises the fact that, given a wholesome custom in head clothing, the consequent effect will be as healthy as it is becoming. Foremost among the sanitary principles which ought to control usage in this

matter are two—the avoidance of any but the lightest pressure, and the admission through the texture worn, or by special apertures, of sufficient air for free ventilation of the head. If these elementary considerations be duly regarded, and sufficient protection be provided against changes of weather, we shall find man the better, not the worse, for wearing his "covering for the head."

#### BACTERIOLOGICAL DIFFERENTIATION.

THE process of differentiation as regards the methods of action of bacteria is gradually being accomplished, and most interesting experiments have been designed to enable us to study such differentiation in connexion with the action of the tubercle bacillus on the animal body. Koch's treatment, of course, depends entirely for its success on an accurate understanding of this question: In a "Study of Experimental Pneumonitis in the Rabbit," Dr. Mitchell Prudden of New York,<sup>1</sup> continuing an account of his researches on the action of dead tubercle bacilli, suggests that as a result of a careful study of the processes set up in the lungs of the rabbit we may make out three different actions of the bacillus tuberculosis and its products: (1) The action of the protein—which is set free from these organisms as they degenerate in contact with living cells—which sets up cell growth, and therefore probably a reparative rather than a degenerative action; (2) the caseous degeneration so frequently met with in tuberculous lesions he considers may be due to the action of some metabolic product of the growth of the tubercle bacillus, this product being wholly distinct from the cell-stimulating bacterio-protein; whilst their still remains another factor (3), probably "of toxic nature, to which many of the graver systemic effects of tubercular infection are due." This is an exceedingly interesting subject, and one well worthy of further careful study.

#### THE PUBLIC HEALTH OF ITALY.

AN Italian correspondent writes, under date Sept. 26th:—"The Government continues to display the utmost promptitude in examining every reported case of cholera and giving the results of its examination to the world. The so-called cases of cholera at Capri turned out to be no cases of cholera at all, and the same may be said of a still later announcement as to the appearance of the malady at Nola, in the Neapolitan district of Caserta. This latter case was given with some fulness of detail in the non-professional press, and from this again quoted, with exaggerations, in foreign journals. The following are the facts, taken from the official report of the Government physicians specially deputed to Nola to make the necessary investigation. A woman seventy years of age had died at that place under symptoms supposed to be choleraic, and the leading physician from Caserta performed the necropsy in presence of his colleagues. She was found to have suffered from chronic bronchitis with pulmonary emphysema, coupled with mitral stenosis and general dilatation and atheroma of the heart. There were also indications of chronic nephritis, with general anasarca, while in the intestine there were found some hyperæmia and hæmorrhagic spots on the colon—spots due no doubt to the grave obstacles to the sanguineous circulation. All characteristics of cholera were non-existent, and the symptoms which had deceived the patient's attendants were attributable to her malady in one of its later phases. No circumstance that could explain the appearance of cholera in Nola or its neighbourhood could, on the minutest inquiry, be discovered. Throughout the peninsula and in the islands, adds the Government bulletin, the health of Italy is excellent, the rates of sickness and mortality being lower than for the corresponding statistical periods in recent years."

<sup>1</sup> New York Medical Journal, Dec. 5th, 1891.

## ENTERIC FEVER IN THE NORTH OF ENGLAND.

ENTERIC FEVER is reported to be prevalent at Eslington in Durham and at Runcorn near Liverpool. At the former place it is alleged to be due to a polluted water-supply. Runcorn is more or less a home of the disease, which has been made the subject of Government investigation on more than one occasion.

## CONTINENTAL ANGLO-AMERICAN MEDICAL SOCIETY.

THE annual meeting of this Society is fixed for Oct. 6th at 4.30 P.M. at the Grand Hotel, Paris. At 7.30 P.M. the banquet will be held at the same place. It was hoped that Sir Joseph Lister would have been able to preside, but unfortunately his engagements prevent his visiting Paris.

## FINANCES OF THE MELBOURNE HOSPITAL.

AT the recent annual meeting of the governors of Melbourne Hospital it transpired that the institution was in debt to the extent of £23,000, and there was a general agreement that the hospital could not go on as at present managed. The cost per bed is £112. The matter was referred for consideration and report to the finance and house committee.

## SMALL-POX PREVALENCE.

THIS disease still prevails in the provinces, London being apparently quite free from it. Some forty cases a week are being notified, of which the great bulk are being contributed by Warrington and Halifax. Cases still continue to be occasionally reported from Dewsbury, which suffered so much at the beginning of the year. A case has also been reported from Leicester.

## THE PORT OF LONDON.

DR. COLLINGRIDGE'S half-yearly report shows an excellent amount of careful and intelligent work done under his auspices. He draws attention to the fact that the Customs have no power to detain a vessel except in the case of cholera, yellow fever or plague, and that the quarantine officers' questions do not apply to esoteric or indigenous diseases, or indeed to any but the above-mentioned complaints. These defects cause great inconvenience in administration, and should be remedied as soon as possible.

## FOREIGN UNIVERSITY INTELLIGENCE.

*Buda-Pesth.*—Dr. Imre Navratil, Extraordinary Professor of Surgery, has been raised to the rank of Ordinary Professor.

*Erlangen.*—Dr. Beckmann, Extraordinary Professor in the University of Giessen, has been appointed to the chair of Chemistry.

*Gratz.*—Professor Moeller of Innsbrück has been appointed to the chair of Pharmacology.

*Innsbrück.*—Dr. J. Nevinny, Assistant to Professor Vogl in Vienna, has been appointed to the chair of Pharmacology.

*St. Petersburg.*—Military Medical Academy: Dr. A. V. Yakovlev has been appointed Prosector in Operative Surgery. The number of *privat-docenten* at work in the Academy has reached sixty, seventeen teaching Internal Medicine, six Midwifery and Gynaecology, six Nervous Diseases, four Children's Diseases, and a smaller number other branches of medical science. Clinical Institute: Dr. N. V. Petroff, prosector in the Obukhoff Hospital and *privat-docent* in the Academy, has been appointed to the chair of Pathological Anatomy.

*Tomsk.*—Dr. J. J. Sudakevich of Kieff has been appointed to the Professorship of Pathological Anatomy.

*Vienna.*—Dr. Georg Juffinger has been recognised as *privat-docent* in Laryngology.

## DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Josef Scharff, Director of the Asylum at Brünn and one of the most distinguished alienist physicians in Austria, at the age of fifty.—Dr. José E. Ramos, Director of the Botanic Gardens and Professor of Botany in the University of Havana.—Professor Pilat of Lille.—Dr. Seligmann, Extraordinary Professor of the History of Medicine, Vienna.—Dr. W. J. Porai-Koshitz, *privat-docent* in Dermatology in the University of Kharkoff.—Dr. K. J. Leonoff, formerly senior surgeon of the 8th Russian Uhlan regiment, who was, in addition to being a very scientific man, a great linguist. He was conversant with Hebrew, Arabic, Persian and Sanskrit, and with nearly all European languages. He died at Yalta, in the Crimea, at the age of sixty-three.—The death is announced of the Professor of Oriental Languages in Halle, August Mueller, who rendered great services to the history of medicine by his works on ancient Arabic medicine.

WE have to announce with regret the death, on Monday last, at North Berwick, of Alexander Keiller, LL.D. St. And., M.D., F.R.C.P., F.R.S. Edin., Consulting Physician for Diseases of Women at the Royal Infirmary, Edinburgh, and the holder of many other appointments in the northern capital. We hope in an early number to give a record of the life and work of the late distinguished physician.

THE Royal Commissioners appointed to consider the question of the water-supply of the metropolis will, on Wednesday next and two following days, resume their meetings, under the presidency of Lord Balfour of Burleigh, for the reception of evidence.

THE Harveian Oration will be delivered at the Royal College of Physicians, Pall Mall East, by Dr. J. H. Bridges, at 4 P.M. on Tuesday, Oct. 18th.

## CHOLERA.

## CURRENT NOTES, COMMENTS AND CRITICISM.

IT is a source of satisfaction to learn the truth about the conduct of the people of Hamburg when face to face with the calamitous sickness that has prevailed in their city since the middle of August last, and which is now happily fast subsiding. The statements which were originally promulgated as to their utter helplessness and want of organising power to cope with the epidemic were, if not altogether false, grossly exaggerated and sensational statements. The letters of the special correspondent of *The Times* obviously afford a far more accurate, reasonable and trustworthy record of the events making up the history of the epidemic. What are the facts? For the first few days the number of attacks was relatively small, but shortly afterwards the epidemic began to assume alarming proportions. Where the cases could be counted by fifties they were soon to be counted by the hundred, and in about a week they reached over a thousand per diem. Up to Aug. 20th there had been only 86 cases of cholera distributed over several days, and on the 22nd, the day the disease was officially recognised, they were 200, and by the 27th they had reached the maximum of 1101. Occurrences of this kind would be likely to strain the powers of the best organised community in the world. The preparations and arrangements for coping with such a state of things were not, and could not reasonably be expected to be, adequate or perfect. Cholera in Hamburg comported itself very much as it

does in India and elsewhere, when it takes, what may be termed, the "explosive" form of a severe outbreak. The shape assumed by such an outbreak, if graphically rendered in diagrammatic outline, may be likened to that of a truncated cone—with a difference however. It rises rapidly to a maximum, continues so for a brief period and then progressively declines, but the line indicating its descent slopes gradually down and is very different to that which represented its almost vertical ascent to a maximum. In this respect an outbreak or epidemic of cholera is more nearly allied to one of influenza than to an epidemic of typhus fever for example, in which contagion from person to person is the dominating factor, for here a diagrammatic figure outlining the rise, progress and decline of the epidemic would assume a cigar or fusiform shape. The probable explanation of this form of cholera outbreak may be adverted to later on; meanwhile, we are glad that their conduct—the really splendid energy of which the Hamburgers may be proud, says *The Times* correspondent—has been fully vindicated. Time was the great difficulty—want of time to make the necessary arrangements was the enemy they had to fight in confronting the cholera. If anyone will try to realise the difficulties that would arise on a small scale from the sudden and unexpected arrival of a hundred people at one of our largest and best-managed hotels, he can easily conceive that its organisation and administration might be for the moment severely tested. But in the case of persons sick and dying of cholera the requirements are infinitely greater and more urgent. A battle causes an epidemic of wounds and injuries, and we all know the strain that this imposes on the best organisation that was ever designed, where the administration is in the hands of men accustomed to provide for such emergencies and trained to act together in that kind of work. It needs such a clear appreciation of principles and mastery of details in regard to transport and hospital management, as well as such correctness and promptitude of judgment, as to amount to a sort of genius. The authorities at Hamburg rose to the occasion, and we are assured by Dr. Koch and other competent authorities that they did their work promptly, manfully and well.

According to the official return of the total number of cholera cases from the outbreak of the epidemic in Hamburg until Sept. 24th, 17,157 persons were attacked by the disease, and of these 7339 succumbed.

But it is to the very ably written tenth letter of *The Times* correspondent, headed "The Sins of Hamburg," and published in that paper on the 27th ult., that we particularly desire to call attention. The moral of the story which is there told, like all stories worth the telling, lies on the surface; its lesson cannot be missed. It is in the application of it that people are likely to falter and fail. The sudden explosion of cholera in Hamburg was apparently a case of wholesale water poisoning. Practically it signifies nothing for the present whether the foul water were the nurse or parent, whether it disseminated or created the cholera poison. The case that seems to have been proved to demonstration in the meantime is this: Here was a city in which the drainage was fairly good, the population not greatly overcrowded, no famine, and but little prevalence of the direst sort of poverty among them, with a creditable condition of house and personal cleanliness; but the drinking water was foul. The sewage may be graphically said "to go out at the basements and in at the roofs of the houses after taking a little tour in the river and the waterworks." This intimate connexion between the prevalence of cholera and contaminated or bad water-supply has been borne in upon us on all sides. There has been cholera for the past six months in France. The first outbreak of the disease took place in the Nanterre prison and asylum early in April last. It was alleged to have been caused by the introduction of contaminated water from the River Seine. The last outbreak in France took place at Portel, a fishing village in the vicinity of Boulogne; sixteen cases occurred and the cause in every case was traced to the drinking of impure water from a well which has since been closed by the sanitary authorities. Boulogne itself has escaped; the disease has not appeared there. Samples of water from that town have been chemically tested and found to be free from impurity. To complete the picture, cholera appeared in the suburbs of Paris to the west and north and long lingered there before it spread by the River Seine to Havre and implanted itself in Paris. The disease was attributed in these cases also to the use of impure water from the River Seine fouled at various places by sewage. *En passant* we would here

call attention to the diagram on another page, representing the daily death-rate from cholera in Paris and its suburbs. It does not signify from a practical point of view whether the true cause of the disease be a comma bacillus, a spirillum, or a vibrio, and their relations one to another, or whether it be any other vitalised agent, the lesson to be learnt is the same; and the two reports which have just been issued from the Medical Department of the Local Government Board regarding the causes of the widespread prevalence of fever in the towns of Rotherham, Rawmarsh and Greasbrough, in the West Riding of Yorkshire, and of the outbreak of typhoid fever at King's Lynn, Norfolk, bring this subject of our water services in this country and the dangers to which a community is exposed conspicuously before us. In these cases also the disease was traced to water pollution. Such pollution may to-day be the cause of enteric fever and to-morrow of cholera. The medical or scientific aspect of the question is another matter. We do not of course intend to minimise or depreciate its importance, for it goes without saying that it is vastly important, and that a logical mind is impelled to seek for and identify the true cause and to differentiate it, if possible, from everything else. But the practical outcome, the object lessons, of the events which have recently taken place on the Continent and elsewhere have tended to demonstrate the importance of a pure water-supply as a safeguard against cholera, as well as against other diseases which are perennial with us, whereas cholera is an exotic and only an occasional visitant.

It appears that Professor Pettenkofer of Munich, who has been actively engaged in studying and observing the disease, together with Professor Koch, during the Hamburg epidemic, considers that the latter's theory of the origin of cholera has not altogether stood the test of experience in Hamburg. It has not been proved, according to Professor Pettenkofer, that the pestilence was brought there in the way indicated by Professor Koch, or that the comma bacillus is the sole cause of the Hamburg epidemic. As will be readily understood by those acquainted with Professor Pettenkofer's ground water theory, he considers that a combination of the two views is necessary to explain all the phenomena of the epidemic. But as it is stated that Professor Pettenkofer intends to publish the results of his observations and conclusions, we need say no more on this head.

There are, however, several points of great scientific interest which still require to be settled before the scientific horizon can be said to be clear. One of the difficulties attending the complete acceptance of the cholera bacillus theory of causation is to account for the occurrence of isolated and sporadic cases of that disease, which in the aggregate amount to a large number—in India, for example. One man is attacked and dies of cholera in a barrack-room occupied by a number of others, the air, food, water-supply and all other conditions being the same for all alike. There is, perhaps, no other case of cholera in the station at the time, nor is there any history of any having occurred before; and this is not at all an uncommon but a frequent occurrence in India at certain seasons, and outside and beyond the so-called endemic area. The relation of these cases to larger outbreaks and epidemics has not hitherto been exactly defined, for when an epidemic occurs later on it does not at all follow that it should be at the same place or time, or soon after the occurrences to which we are referring; and parallel with this is the inquiry, How did the River Seine become infested with the comma bacillus, and how was the cause of the disease introduced into Hamburg, or, to take the latest example, into the well at Portel, the fishing village near Boulogne? Some light may be hereafter thrown on these subjects. Of course it is often excessively difficult to trace out the natural history and descent of an animal or micro-organism and it may be impossible to trace the lineage of a disease, and yet the failure to do so would not at all invalidate the conclusion that it depended upon a specific organism like the comma bacillus.

While the military manoeuvres in Germany were postponed, those in France took place during the present autumn, and the *fête* of the 22nd ult. was celebrated. Whether these gatherings have had any effect or not on the prevalence of cholera in France it would be hard to say. The disease still lingers in that country, although the number of cases is relatively very small considering its population. There is a progressive decline of the disease in Hamburg, satisfactory reports from Vienna and Galicia, and from Brussels, Berlin, the Netherlands, St. Petersburg and New York, notwithstanding that the disease still prevails more or less in these places.

A word regarding the correspondent of the *New York Herald*, who got himself inoculated for cholera in Paris by M. Haffkine. This gentleman has gone through a great experience in the Hamburg hospitals, and he enters into a description of all the details connected with the various and different tests to which he has subjected himself. As regards their scientific and practical results, however, they are valueless, for we knew already that nurses and medical officers did not run any great risk of catching the disease by contact with the sick in cholera hospitals; and as regards more direct methods of infection, a negative result in any individual case will not prove that the apparent immunity was conferred by any previous inoculation; and if the experimenter were attacked and died of the disease we should be no wiser as to how he contracted it, although the occurrence would indicate that in his particular case the previous inoculation had not protected him. There is hardly any test to which some individuals have not at some time or other subjected themselves without contracting the disease, but this fact has not carried conviction to the minds of anyone or served to establish any particular view on a scientific basis.

We are glad to notice that the simplicity and efficacy of the preventive measures adopted by the Local Government Board in this country have attracted attention on the Continent.

It is reassuring to know that, with the exception of a case or two at Hull from the *Uranus* from Hamburg, this country remains free from the disease. When such success has been attained up to the present in keeping cholera out of England it is extraordinary to find a body like the Town Council of Grimsby suggesting to its fellow port sanitary authorities that they should apply to the Local Government Board for powers to detain all ships from infected ports in quarantine for seven days. It is said that the Hull authorities have strenuously dissented from this view, and we trust that no port authority in this country will be found to support the retrograde proposal of the Grimsby Town Council. Abroad the disease appears to be distinctly waning in both St. Petersburg and Hamburg. A few cases are still reported from Berlin, and there appear to be signs of the enemy still in Holland—e.g., at Rotterdam and the Hague. The prevalence of choleric diarrhoea is diminishing in Paris, but a few cases of what appears to be genuine cholera are reported from the vicinity of Boulogne. America appears to be practically free, there having been no extension of the disease which appeared, in spite of quarantine, in New York city. The German Imperial Government are now alive to the necessity of stringent sanitary administration, and a Bill is being drafted which will comprise regulations as to infectious disease applicable to the whole empire. We have already in the foregoing part of this article referred to the well-informed statements which have been made regarding the sanitary condition of Hamburg, and drawing attention to the state of the canals and of the Alster Lake, as well as of the conditions of the water-supply. It appears that the water drunk at Hamburg is nothing but Elbe sewage, subjected to no filtration, but only to a rude and incomplete subsidence. We have pointed out that facts have been adduced against the current hypothesis of the introduction of cholera into Hamburg by means of Russian emigrants and some stress laid upon a theory of soil development of the disease after Pottenkofer. But whether introduced from Russia or developed from seeds of previous epidemics left in the soil, under seasonal influences, is a problem to be settled only after much patient investigation in the future.

## THE CHOLERA IN FRANCE.

PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

### THE DEVELOPMENT OF THE EPIDEMIC.

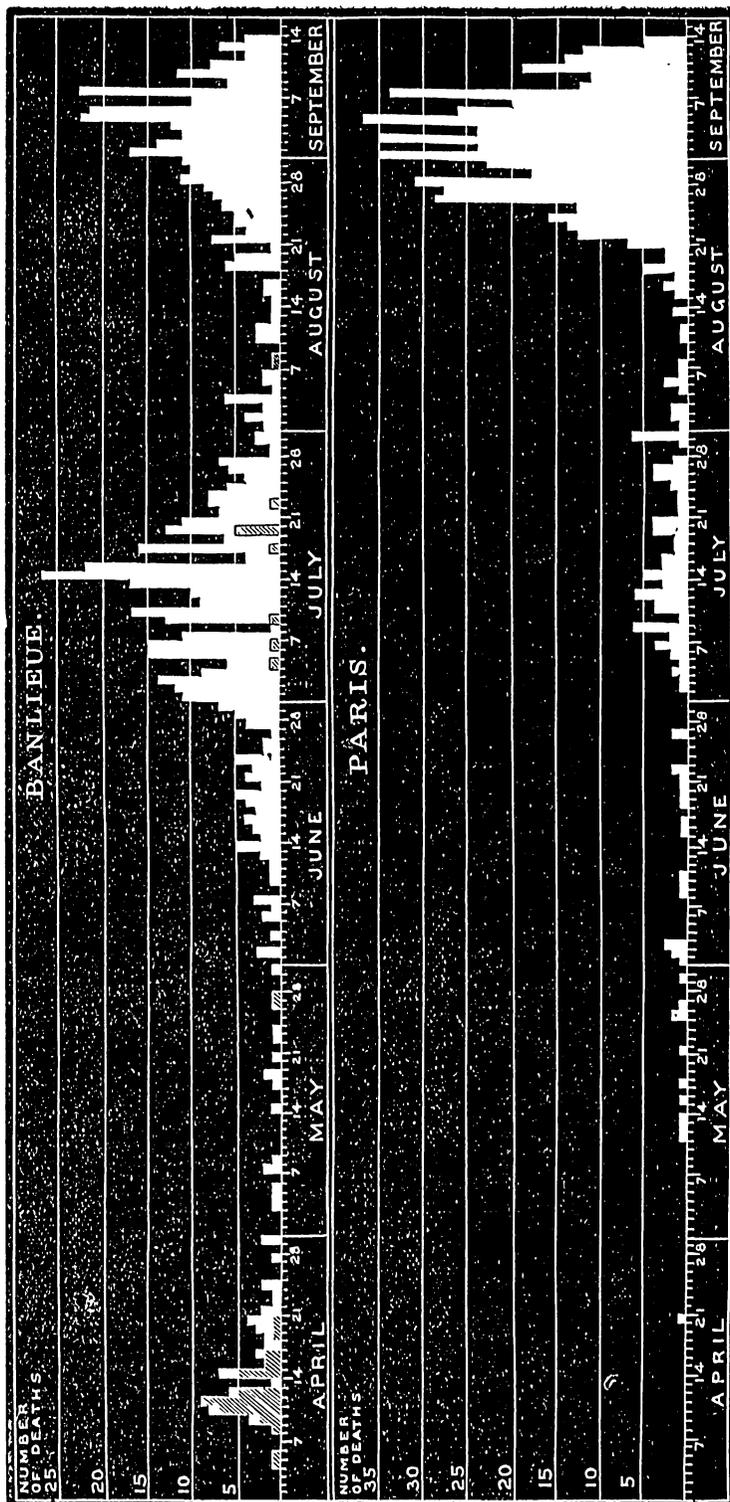

ON Sept. 13th Dr. Brouardel stated before the Academy of Medicine that the first cases of cholera occurred at Bakou on June 22nd, at Nanterre near Paris on April 2nd, at Hamburg on Aug. 11th, and at Havre on Aug. 2nd. It is something to find that the truth is at last acknowledged and this by so high an authority. In July, when I was last in Paris, every effort was made to conceal the real facts. It was said that out of ten clearly defined cases there were as many as nine deaths. It was recognised that the deaths were most rapid, occurring after a few hours; but, nevertheless, we were asked

to believe that this was only cholera nostras. The fact that the disease did not spread was not attributed to better hygiene and a more strict and skilful application of prophylactic precautions, but the slowness of development was taken as a proof that it was not an epidemic of cholera. Now, however, the disease has spread, not to a very large extent, but in any case there are already more victims than during the entire epidemic of 1884; and in that year no attempt was made to disguise the fact that true cholera prevailed in Paris. The only difference is that the epidemic spread much more rapidly in 1884 and lasted but a short time. It had been simmering in the outskirts of Paris for several months, but when it gained a footing within the town it increased very rapidly. There were two deaths on Nov. 4th, 1884, and 110 deaths on the 10th of the month. But, on the other hand, there were only 938 deaths in all, and, adding to these the deaths which occurred in the suburbs, the total was close upon 1000. In the present epidemic the number of victims is already in excess of the cholera death-roll of 1884, only this year the suburbs of Paris have suffered more acutely. Dr. Paul Brousse, reporter of the Permanent Committee on Epidemics, and Municipal Councillor, has prepared a diagram of the present epidemic (which we reproduce on the opposite page) to show the daily, weekly and monthly death-rate from cholera in the suburbs and within the fortifications of Paris. The diagram illustrates how slowly the cholera has spread but how much it increased during July and September in the suburbs and during September in Paris. The figures are as follows:—In the suburbs there were 24 deaths in April, 14 in May, 76 in June, 299 in July, 123 in August, and from Sept. 1st to 14th, 173 deaths. This gives a total of 709 deaths in the suburbs of Paris, but within the department of the Seine; for it must be noticed that there are other districts that may also be considered suburbs of Paris, such as Sarcelles, where the Belgian bricklayers from Jumet contracted cholera, which are not included in these statistics because they form part of another department or county. In Paris—that is, within the fortifications or walls of Paris—there was one death attributed to cholera in April, and this occurred on the 21st. In May there were 10 deaths, in June 19, in July 83 and in August 229. Towards the end of August the cholera had greatly increased. During the first twelve days of September there was an average daily death-rate from cholera of 24, but there has been a considerable decrease since the 13th of the month. Altogether, from Sept. 1st to Sept. 19th there were 357 deaths attributed to cholera within the walls of Paris. Adding this to the 342 deaths recorded during the previous five months, there was a total of 699 deaths within Paris. This figure, taken in conjunction with the 709 deaths in the suburbs, gives a grand total of 1408, and is therefore considerably above the epidemic of 1884, which, as already stated, for Paris and the suburbs, did not quite reach the total of 1000. These figures demonstrate only too painfully that I was justified when, in June and July, I insisted on the importance of the few cases that then occurred. I should also add that at the Nanterre prison and asylum there were 43 deaths, most of them occurring in the month of April. It is difficult to say whether these should be considered as suburban or Parisian cases; for, though the prison of Nanterre is in the suburbs, the patients, mostly vagabonds and beggars, sickened and died very shortly after their arrival from Paris. These 43 deaths increase the general total to 1451 deaths.

### THE ORGANISATION OF MEDICAL INSPECTION, OF DISINFECTATION, AND OF THE AMBULANCE SERVICE

The statistics as to the number of cases of cholera in the Department of the Seine should be fairly correct, for the most careful measures are taken by the Prefecture of Police so as to receive prompt and accurate information. M. Besançon, the courteous and amiable Chief of the Second Division at the Prefecture of Police, who in France represents the administrative side of sanitary reform, and who is a faithful attendant of the International Congresses of Hygiene, was kind enough to explain this mechanism. First I was shown a little pocket-book such as has been distributed to every doctor in Paris. It is of the size of a post-card, and should never leave the practitioner's pocket. On the inside of the wrapper the following is printed: "Prefecture of Police, Second Division, Fourth Bureau, Epidemical Service. Extract from the Decree of Aug. 29th, 1892:—Article 6: The declarations at the Town Hall of all cases that seem likely to prove cases of cholera is obligatory, and must be made within a delay of twenty-four hours by the doctor or medical officer

DIAGRAM REPRESENTING THE DAILY DEATH-RATE FROM CHOLERA IN PARIS AND THE SUBURBS.

The upper column of the diagram represents the daily, weekly and monthly death-rate due to Cholera in the SUBURBS OF PARIS AND WITHIN THE DEPARTMENT OF THE SEINE, from the beginning of April until the 14th of September. The shaded portions represent the deaths within the DEPARTMENTAL PRISON AND ASYLUM AT NANTERRE.

The lower table shows in graphic form the number of deaths from Cholera within the FORTIFICATION WALL OF PARIS during the same period.

who has seen the case, by the head of the family or the persons who are nursing the patient, and by any person with whom the patient is lodging. In Paris this declaration must be made at the Prefecture of Police, or at the Town Halls (*mairies*). Article 10: Any infraction of the present decree shall be reported and give rise to a prosecution according to Article 14 of the law of the 3rd March, 1822, which punishes by imprisonment of from three to fifteen days and a fine of from 5 fr. to 50 fr. all who have disobeyed, in sanitary matters, the orders given by competent authorities."

The pocket-book contains twelve folded letter cards addressed to the "Prefect of Police; Epidemical Service," with notice in the corner that the letter need not be stamped. Inside is a printed formula which has to be filled up, by which Doctor — declares that such person of such an age, residing at such an address, "presents choleric symptoms." Then there is space remaining for other details relating to disinfection, removal of the patient &c. The private practitioner on seeing the patient should then and there fill up the letter, gum down the edges, remove it from the pocket-book and drop it into the nearest letter-box. The inside of the wrapper at the end of this little pocket-book gives instruction for the procuring of ambulances and for disinfection.

At the Prefecture of Police a record of each case is kept on two separate cards. One card is white and headed by the name of the patient, and of course these cards are placed in boxes according to alphabetical order. The other card is yellow and is headed by the address of the patient. The latter is the most useful, for here are found in alphabetical order the streets where cases have occurred, and a glance will show where the epidemic is causing the most harm. Every morning at eight o'clock six doctors attached to the Permanent Committee of Hygiene<sup>1</sup> arrive at the Prefecture of Police, study these white and yellow cards, and determine what places they should inspect during the course of the day. In time every case reported is visited by one of the doctors from the Prefecture. These official medical inspectors carry with them white cards of a larger dimension than those already described. On the top of the card is a space for the address of the place visited. These follow personal details concerning the patient, the date of the illness and details relating to the malady. After this there is a space to fill up with information as to cases, if any, of contagion in or near the house. Another space is left, so that the nature of the water consumed in the house may be mentioned; and finally, all the details concerning disinfection have to be given.

In any case in Paris the necessity of disinfection is at last fully recognised. The services for the disinfection of private houses have been organised quite recently, but great progress has been accomplished in a very short time. The principal disinfecting station is in the Rue des Recollets, near the Eastern Railway Station, and its organisation is more perfect than anything of the sort I have seen in England. Of course the premises are divided in half with two separate entrances—the infected and the disinfected sides. The disinfectors arrive in the morning on the clean side. They are then introduced into a little room, where they take off all their clothes. From this there is a middle room with the necessary apparatus for washing and for taking a douche. In a third room they find their working clothes, and from this third room they reach the infected side of the establishment. To return to the clean side, they must leave their working clothes in the third room, take a douche in the middle room and put on their ordinary clothes in the first room. The disinfecting stoves are of course walled round, the entrance to the stoves being on the infected side, while the objects, when purified, are taken out on the opposite and clean side. What is now known as the official stoves only are used. These act by steam superheated under pressure. The temperature is generally about 118° C., and the operation does not require more than about twenty-five minutes. But these stoves have been often described. They are the same as those that are used in most parts of the world, from Belgium to the Caucasus, or from the Suez Canal, at Gibraltar and on board the large ocean liners. The attendants at the Rue des Recollets declared that they had received but few complaints as to damage done to the clothes they had disinfected.

The establishment was somewhat in a state of confusion at the time of my visit, as a new stove was about to be introduced, and it was necessary to build larger storing rooms in

which to place the objects that have been disinfected. It is a rule that no object, on being withdrawn from the stove, shall be put on the ground. It must be placed on large shelves that are built for this purpose. Last week I mentioned that the number of disinfecting operations performed from Sept. 1st to 15th amounted to 1598. This figure had increased to 2271 on Sept. 23rd. Never has such extensive disinfection been previously accomplished in Paris, and to meet such a demand it is necessary on all sides to increase the number of stoves and the size of the premises. These figures do not include the disinfection of passengers' luggage and other goods coming by train, but apply only to the disinfection of houses where there have been cases of cholera and other contagious diseases.

The disinfectors, having put on their working clothes, start out to the various houses where their services are required. They are conveyed in large closed carts. On reaching the house which has to be disinfected they put on a large pair of canvas trousers and a large blouse which fits tightly round the neck and the wrists. They have with them a counterfoil book on which they inscribe on both sides all they intend to take away. One list is left with the owner, the second list is on the other half of the leaf and remains in their book. All the bedding, curtains, carpets and soiled linen are carefully folded up in canvas and securely packed. This is placed in the closed cart which is waiting in the street. The disinfectors have with them wooden jugs of 18 litres capacity, and packages containing 50 grammes of sulphate of copper, and other packages containing 7.5 grammes of bichloride of mercury and 30 grammes of tartaric acid. One of the latter packets is emptied into one of the wooden jugs and dissolved in water. The solution is poured into the pulveriser, and the disinfecter proceeds to systematically work the spray over the walls and the furniture and into all the corners. The other wooden jug is half filled with water, fifteen packets of sulphate of copper are added, and then the jug is filled with more water. When the crystals are dissolved the solution is used to pour down the drains, to wash the floor and walls of the closets and to mix with the excreta of the patient that may still be found on the premises. This completes the process of disinfection. The disinfectors then remove their overalls, which are packed in a small bag and placed in the cart to be disinfected in the stoves with the bedding &c., and before proceeding further spray themselves over with the mercurial solution. Thus the danger of spreading infection during the process of disinfection is reduced to a minimum. It will be remarked that the process of fumigation has been entirely abandoned. The Paris authorities have greater confidence in the antiseptic properties and the penetrating powers of the mercurial spray.

In the suburbs of Paris the linen, bedding &c. are not carried away, but a portable disinfecting stove is brought to the house and the disinfection by superheated steam is practised in the street at the patient's door. For this purpose there are in the Department of the Seine, but outside the walls of Paris, fourteen portable stoves. Only two of these portable stoves are on the south side of the Seine, at Secaux and Villejuif. Two more are to the east of Paris, at Oharenton and Vincennes. These four stoves cover one half of the circle round Paris; the fact that the ten other portable stoves are in the other half of the circle eloquently indicates where the cholera epidemic has found most of its victims. The ten stoves are distributed as follows:—One at Pantin, one at Aubervilliers, two at St. Denis, one at St. Ouen, one at Clichy, one at Neuilly, two at Courbevoie and one at Boulogne. With each stove there is a pulverising apparatus.

It is important to add that all these disinfecting operations are carried out absolutely gratuitously. No payment is demanded either from the rich or the poor. It was felt strongly that any question of payment would tend to cripple the action of the administration. Success depended on the principle of perfect equality. Some wealthy persons might not object to pay, but the poor would strongly object to being treated on a different and on a humiliating footing. The enforcement of sanitary measures must not tend to pauperise certain sections of the population. Therefore disinfection is at once obligatory and gratuitous all round, and there is no difference whatsoever made between rich and poor.

Disinfection was first practised at the Rue des Recollets, because there is here a large night refuge, where nearly 300 people are given shelter for three days in the month. Persons applying for this help were required to strip, a foot-bath and douche were given them and a suit of canvas clothes

<sup>1</sup> See, with regard to the creation and functions of this committee, THE LANCET of July 23rd, 1892.

provided for the night. In the interval their own clothes were disinfected, and for this purpose a disinfecting stove was placed close at hand. This stove, intended originally only for those who came to the asylum or casual ward, was the nucleus of the public disinfecting station now so well organised and so generally appreciated. The disinfecting station in the Rue du Château-des-Rentiers, beyond the Orleans railway station, had a similar origin. Here also there is a night refuge, organised likewise by the Paris Municipality. The washing, the douche and the disinfection of the clothes are similarly enforced, and here likewise the number of disinfecting stoves is being increased, for this has become the public disinfecting station for the south side of the river. On the evening preceding my visit a poor man who was enjoying the hospitality of this asylum was taken ill a few minutes before midnight. The manager of the refuge at once removed the patient from the dormitory, poured a sulphate of copper solution on the dejections and telephoned for the ambulance. The man was promptly removed to the hospital, where he died at two in the morning. The period of illness certainly did not last more than two hours and a quarter. This is the first case of cholera that has occurred in the refuge. The next day the walls of the dormitory were treated with the mercurial spray; and 207 mattresses, 267 rugs and 414 sheets were disinfected in the stove, which is fortunately on the premises. The closets were drenched with a solution of sulphate of copper and the street pavement outside the night refuge was washed with a disinfectant. It would be difficult to do more. While speaking of these night refuges, I might mention that the cost, including all the service administration &c. of receiving the poor, of giving them a footbath and douche, of lending them a suit of clothes for the night, of disinfecting their clothes, of giving them a good bowl of meat and vegetable soup in the evening and a piece of bread in the morning, amounts per person relieved to 55 centimes at the Rue des Récollets and to 42 centimes at the Rue du Château-des-Rentiers. Finally, as an indication of the humane sentiment that animates the management of these municipal refuges, I should not omit to describe the care with which the clothes are disinfected. They are not folded up as is the practice at our English casual wards, so that they come out of the stove all creased. On the contrary, sticks are provided, to which the clothes are fastened in such a manner that there are no creases and no one can tell that the wearer has been in a refuge.

The third disinfecting station is in the Rue de Chaligny, beyond the Faubourg St. Antoine, and is only separated from the Hôpital St. Antoine by a wall. The principle of management is the same at all the three stations. The division between the infected and the disinfected sides is strictly observed, and there are the three compartments for the disinfectors, so that they may change their clothes and take a douche when they finish work.

At the Rue de Chaligny there is also the municipal ambulance service. The other municipal ambulance service is in the Rue de Staël on the south side of the river, near the Boulevard Vaugirard. I will describe the latter as being the more perfect of the two. There is a small central building where three trained nurses live. On one side there are the door and the stabling for the ambulances that are ready to start, and on the other the infected ambulances that have returned from service. These ambulances have the form of small omnibuses; they are absolutely bare inside and lined with tin, the angles being rounded off. The only furniture is an iron folding shelf that serves as a seat for the nurse. Then there are portable iron stretchers, which can be folded up in the form of an arm-chair or laid out as a bedstead. Communication by telephone or telegraph is open day and night with these ambulance stations. When the ambulance is called to fetch a patient the coachman puts on a canvas suit very similar to those worn by the disinfectors. The nurse puts on a white linen gown that fits tightly round the neck and the wrists and descends to the feet. She also puts on her service shoes. On reaching the house the coachman and the nurse, with the aid of whatever assistance may be found on the premises, place the patient on the iron folding chair, on which a small mattress and rugs have been placed. The patient is driven to the hospital and then the ambulance returns to its station. A door close to the entrance on the infected side admits the nurse to a lavatory, where she removes her gown and her shoes and washes herself in a mercurial solution. The coachman in the meanwhile has made a bundle of the mattress and rug, which are

then ready to send to the disinfecting stove. With the pulveriser he then proceeds to disinfect the inside of the ambulance waggon. The ambulance is now ready for the next case, and is sent over to the other side of the yard. At the back of the yard are the stables, where two horses are always kept ready harnessed. The ambulance carriages cost £120, wheels with indiarubber tyres cost £18 more, and the folding iron stretchers cost £5 each. In the month of August the nurses at the Rue de Staël removed 655 patients, of whom 114 were infectious or contagious cases. Up to Sept. 24th they removed 484 patients, and had generally to deal with three or four cholera cases every day.

The disinfecting stoves and ambulances are under the control of the Prefecture of the Seine, but the Prefecture of Police has also under its orders a number of carriages for the removal of the sick. A doctor or the friends of the patient may therefore apply either to the Prefecture of Police or to the municipal ambulances of the Rue de Chaligny and the Rue de Staël. This dual authority is somewhat perplexing, and it is most regrettable that it should have lasted so long. Finally, if a patient is removed to the hospital in a cab or private carriage it will be found that the Prefecture of Police has placed a policeman at the entrance of every hospital. The cab or carriage is made to enter the yard of the hospital, and the policeman is there to see that it does not come out again till it has been disinfected. In case of a cab the cabman receives 1s. 8d. as a compensation for the delay caused by the disinfection. This, however, does not take long, being done with the pulveriser and the mercurial solution.

Such are some of the methods and the precautions which the authorities in Paris are now adopting. They constitute a most notable improvement on what has been done during previous cholera epidemics.

#### NOTES ON TREATMENT.

Our Paris correspondent, writing on the 28th ult., says that it is reported that from Sept. 17th to the 24th there occurred at Portel, a fishing village near Boulogne-sur-Mer, ten deaths from cholera. The director of the Board of Health arrived there on Saturday with a disinfecting stove, and Dr. Aigre, Mayor of Boulogne, visited the place on Friday. Steps are being taken to limit the outbreak. A commission, appointed by the Municipal Council of Paris, has left for London and Glasgow, in order to study the methods employed by water companies in these towns for the filtration of drinking water. At a meeting of the Académie de Médecine Dr. Gibert of Havre uttered a protest against the closing of ports in times of cholera to vessels hailing from contaminated countries. He states that during the present epidemic Havre has so far suffered a loss of 30,000,000 francs from this cause. He points out that England has succeeded in restricting the outbreak to twenty-five cases simply by burning all objects belonging to a cholera patient, whilst keeping her ports free to all comers. At the same meeting Dr. Gaillard reported the results of a mode of treatment followed by him at the extemporised hospital situated in bastion 36. Whenever a patient was admitted in the algid stage his body was at once vigorously rubbed, repeated hypodermic injections of caffeine and ether were given, as also inhalations of oxygen. If no benefit accrued two litres (for an adult) of the following saline solution were injected into the internal saphenous vein:—Sterilised distilled water, 1000 grammes; chloride of sodium, 5 grammes; sulphate of sodium, 10 grammes. This generally suffices to revive the patient. Sometimes, however, the transfusion has had to be repeated (once five times), but an interval of at least eleven hours is allowed to elapse between the injections. When the patient is able to swallow he is given a litre of sweetened water containing fifteen grammes of lactic acid. This is followed by champagne, coffee and nutrient enemata. Dr. Gaillard's results stand thus: Cures, 173; deaths, 164; under treatment, 23—total, 360. Of the cases cured, twenty-five owe their lives to transfusion of sterilised serum. One operation generally sufficed; in three cases only was the transfusion repeated once. Fifty-two very serious cases were saved by the lactic acid treatment only, without transfusion. At the height of the epidemic there were as many as sixty-two male nurses in the hospital; of these, only one contracted the disease, and he was saved by transfusion. The youngest of the transfused patients was aged eight and the oldest—there were three of them—fifty-six years.

## CHOLERA IN GERMANY.

Our correspondent, writing from Berlin, says:—"The numbers of cholera cases and deaths reported from Hamburg on the 16th inst. were 276 and 136; on the 17th, 286 and 127; on the 18th, 241 and 115; on the 19th, 206 and 105; on the 20th, 211 and 100; on the 21st, 180 and 97; on the 22nd, 199 and 69; on the 23rd, 115 and 56; on the 24th, 81 and 49; and on the 25th, 126 and 47. After Professor Koch's last visit to Hamburg it was given out that he had spoken of the anti-cholera measures there in terms of the highest praise. The *Frankfurter Zeitung*, however, has received the following much more credible report from that city:—"It is true that Professor Koch praised some of the measures taken by the authorities, but in general he made no attempt whatever to conceal his dissatisfaction, and even severely blamed this and the other. He frankly declared to the members of the Commission that, if the State (i.e., the little republic of Hamburg) did not at once provide good drinking water for the people, we should not get rid of the epidemic. The distribution of boiled water and spring water was only a temporary make-shift, which could not last long, because, for one thing, even comfortably situated people could not long afford to boil all the water they use in their homes themselves." The immediate results of Professor Koch's visit were that the Commission resolved to have all the cisterns cleaned, the foci of contagion disinfected and Abyssinian wells sunk. Professor von Pettenkofer of Munich, one of the first authorities on cholera, who is by no means altogether at one with Dr. Koch, spent some days at Hamburg last week, studying the epidemic. Dr. Koch visited Stettin on the 19th instant and inspected the waterworks there. He is reported to have declared that the Oder was undoubtedly infected with cholera bacilli, and that, as the water-supply of Stettin is taken from that river, the city was in danger unless the filters kept the bacilli out, which was possible only if the water passed through at the rate of 100 millimetres an hour at most, whereas the rate then was from 200 to 300. This excessive rapidity was due to waste, the Stettiners having used during the last few months from one and a half to twice as much water as necessary. The magistrates have ordered the enlargement of the filtering apparatus, and the work has already begun. An interesting observation has been made in the Hamburg suburb of Sankt Pauli, where cholera raged with great severity. In a block of houses which gets its water from the adjacent Altona not a single case occurred. Altona, like Hamburg, takes its water from the Elbe, but filters it, which Hamburg does not. The fury of the epidemic, however, is not due to bad water alone, but also to the overcrowded dwellings of the poor."

A Hamburg correspondent writes:—"The Hamburg Waterworks, to which so much attention has been directed, are situated about a mile and a half to the west of the town. The intake from the Elbe is a little higher. There is no attempt to purify the water, the water-works being a mere pumping-station to force the water with all its impurities into the mains supplying the town. In this suburb the first cases of cholera occurred, the first case, so far as can be discovered, being a man employed in cleaning ships; but, as he rapidly became unconscious, it is not known on what ships he had been employed. Thus the exact source of the original infection can never be known. Immediately in his neighbourhood several similar cases occurred. The authorities declare that it was not till then that the comma bacillus was seen, and therefore that they could not be sure that cholera was present. Asiatic cholera is a most marked and characteristic disease, having specific symptoms and being invariably attended by great mortality. These symptoms were present, and a great mortality existed—far greater than could be possible with mere European choleric. Moreover, the comma bacillus has not yet by any means been universally admitted to be the cause of cholera, in spite of all the energy of Dr. Koch and his supporters. Is, then, a town to be allowed to have a severely fatal disease, attended with all the symptoms of cholera, and yet to be regarded as perfectly free from infectious disease, because a bacillus which is hypothetically looked upon by some to be its cause has not been recognised? Cholera, unfortunately, is not a theory but a reality, and will make its presence felt by its mortality; and it should be the duty of every place having a disease with all the symptoms of cholera and its mortality to 'proclaim the fact' at once—the bacillus can be searched for afterwards."

## CHOLERA IN AUSTRIA.

Our Vienna Correspondent writes:—"The reports on the course of the cholera in Galicia, which reached Vienna during the last week, led to the expectation that there were only sporadic cases to be met with at Cracow, Podgorze and Wolowice. In the first two towns during the period from Sept. 8th to Sept. 25th only fifteen cases of cholera, with five deaths, have occurred, and these cases showed the specific local character of the disease. The private buildings where these occurred were carefully isolated and their inhabitants kept under medical supervision. As may be seen from the low death-rate, the disease has not been of a very virulent character. In some of the cases infection could be traced to dirty linen. Naturally, disinfecting operations were carried out at Cracow with the greatest energy, sometimes even with curious effects, as in a case in which three young girls were brought to the hospital there with symptoms of gastro-enteritis. It turned out that they had contracted the disease from having eaten fruit which had been disinfected by carbolic acid. At Wolowice only four cases with two deaths occurred a week ago, but no other cases followed. According to official reports no case of cholera has been observed throughout Galicia within the last three days, so that the local authorities believe that the local epidemics are already stamped out. In the meantime medical examination of the passengers arriving from Galicia is carried out in the other Austrian towns, and the importation of meat &c. from the infected districts is prohibited. Last week a railway car containing over 1700 kilogrammes of Galician meat arrived at Vienna, having passed through Cracow. The meat was destroyed by fire. The lack of foresight on the part of the local authorities was also noticeable in the case of supplying Vienna with food. No arrangement had been made to secure the importation of meat from other sources in the case of an outbreak of cholera in Galicia, from which the greatest quantity of meat, eggs &c. is supplied to Vienna in normal times. In Bohemian frontier stations the observation has been made that comma-bacilli may be found also in apparently slight cases of diarrhoea. These cases occur in boatmen who have come on the Elbe from Germany in their barges."

## NOTES ON AN ACCIDENT UNDER CHLOROFORM.

BY SURGEON-LIEUTENANT-COLONEL E. LAWRIE.

No. 1433.—*Mukrum Khan, aged forty, a powerful Afghan Mahomedan male; disease sinus; chloroformed at the Ayzulgunj Hospital on Aug. 19th, 1892, by a student; full anaesthesia in 2 min. 25 sec.*

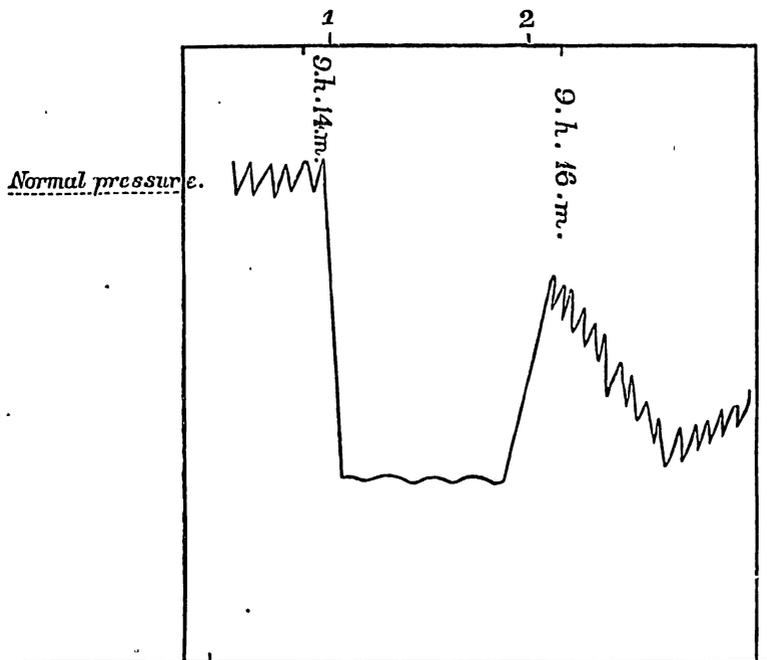

- H. M. S. OBSERVATIONS.
- 8 42 20.—Chloroform on cap; resisting and struggling very violently almost at once.
- 8 43 25.—Stopped struggling; natural breathing.
- 8 43 30.—Chloroform added to the cap; two breaths of air.
- 8 43 45.—Respiration twenty-eight a minute.
- 8 44 45.—Over; cornea insensitive; cap removed.
- 8 45 5.—Shallow breathing; jaw pushed forward.
- 8 45 25.—Natural breathing; cornea sensitive; cap reapplied.
- 8 45 40.—Stertorous breathing; cap removed and jaw pushed forward.
- 8 47 0.—Cornea sensitive; cap reapplied. The cornea became insensitive almost immediately; the respiration became shallow again forthwith, and the jaw had to be pushed forward to relieve it.
- 8 49 0.—Struggling; cornea sensitive; cap reapplied.
- 8 49 40.—Over; cornea insensitive; cap removed.
- 8 50 0.—Respiration becoming shallow; jaw pushed forward.
- 8 50 20.—Respiration stopped. Dr. Lawrie at once jumped on to the table astride of the patient and performed artificial respiration by Howard's method; natural breathing recommenced after 55 seconds.
- 8 51 15.—Artificial respiration stopped; jaw still kept forward.
- 8 52 0.—Normal respiration; jaw let go.
- 8 53 30.—Operation finished.

(The notes of this case were taken by Dr. Lawrie and, after anaesthesia was complete, by a senior student.)

*Remarks.*—Immediately after the inhalation was commenced the patient struggled violently for more than a minute, and it required six or eight students to hold him on the table. Between 8 h. 45 m. and 8 h. 47 m. signs of respiratory failure occurred three times, consequently from 8 h. 47 m. no chloroform was given until 8 h. 49 m. The administration was then proceeded with, and was stopped directly the cornea became insensitive, at 8 h. 49 m. 40 s. After the in-

halation ceased the anæsthesia deepened. At 8 h. 50 m. the respiration began to fail, and it stopped altogether at 8 h. 50 m. 20 s. The patient became deathly pale, and it is probable that there was also reflex stoppage of the heart. Artificial respiration was performed for fifty-five seconds; he then took a natural breath and gradually recovered. The accidental over-dosing in this case emphasises the rule that chloroform should never be administered during the irregular breathing which accompanies violent struggling. It was quite right to hold the patient down, but the chloroform ought not to have been given until he was quiet and the respiration was regular and natural. The rationale of the overdosing is readily explained by the research of the Hyderabad Commission. The Report of the Commission demonstrates that asphyxia renders the respiratory centre extremely susceptible to the action of chloroform, and Experiments 64 and 178 show how narcosis may be produced by residual chloroform in the system after the inhalation of the anæsthetic has been discontinued.

The following is a diagram of part of Ludwig Tracing 3 of Experiment No. 64 of the Hyderabad Commission. The tracing reads from left to right:—

1. At the point marked 1 electrical irritation of both vagi and the administration of chloroform were begun simultaneously.  
2. At point 2 the vagus irritation and chloroform inhalation were both stopped.

In Experiment 64 the administration of chloroform and electrical stimulation of both vagi were commenced simultaneously at 9 h. 14 m. 20 s., and the effect was to send the blood pressure down suddenly almost to zero and to arrest the circulation for nearly two minutes *while free respiration continued*. The air in the lungs was thus gradually charged with chloroform. When the inhalation of chloroform and stimulation of the vagi were stopped at 9 h. 16 m., the blood-pressure rose rapidly again, the circulation was resumed and the chloroform in the lungs was forthwith taken up and conveyed to the nerve centres. Narcosis was produced, and its effect is shown in the tracing by the fall of the blood pressure, which commenced at 9 h. 16 m. and continued until the residual chloroform in the lungs had been got rid of. This experiment reduces what happened in our case to demonstration. Residual chloroform, which was present in the system owing to previous irregularity of the breathing, was conveyed to the nerve centres after the inhalation was discontinued; the respiratory centre became narcotised and the breathing entirely stopped, and but for prompt artificial respiration the narcosis would in all probability have terminated fatally.

In order to prove to my students that it was the method of administration which was at fault and not the chloroform or any constitutional idiosyncrasy on the part of the patient, he

was brought before the class again on the 21st instant and the wound was dressed under chloroform.

The following is the record of the second administration:—

No. 1442.—*Multrun Khan, Afghan Mahommedan male, aged forty, chloroformed at the Afzulgunj Hospital, on August 21st, 1892, by Dr. Lawrie; normal anæsthesia was produced in 4 min. 35 sec.; before the inhalation the heart was examined and found to be healthy; the pulse, which, without my knowledge, was watched out of curiosity by Dr. Leaf, was slow, weak and regular, and it did not vary in any appreciable degree throughout the inhalation or afterwards.*

H. M. S.

OBSERVATIONS.

- 0 21 45.—Chloroform on cap; blowing regularly; cap close.
- 0 22 30.—Natural breathing.
- 0 22 50.—Chloroform added to the cap; two breaths of air.
- 0 23 5.—Respiration twenty-four a minute, regular.
- 0 24 0.—Respiration twenty a minute, regular.
- 0 24 8.—Chloroform added to the cap; one breath of air.
- 0 24 40.—Struggling; regular breathing; cap kept close.
- 0 25 15.—Chloroform added to the cap; two breaths of air.
- 0 25 40.—Snoring.
- 0 26 20.—Over; cornea insensitive; cap removed.
- 0 26 40.—Dressing finished.

The second administration helps to confirm the contention of the Hyderabad Commission that the respiratory centre is peculiarly susceptible to chloroform when it is asphyxiated. In the first administration the respiratory centre was accidentally partially asphyxiated, and full anæsthesia was promoted in 2 min. 25 sec. In the second administration, though the chloroform was given in the same way and the cap was held just as close to the patient's face as in the first, the breathing was natural and regular throughout and anæsthesia was produced in 4 min. 35 sec. Finally, it is probable that the asphyxia, which occurred at the commencement of the inhalation, was a factor in the over-dosing which took place in the first administration. I believe I am right in stating that Case No. 1433 constitutes the first reported instance of an accident under chloroform in which notes of all the events that occurred throughout the entire administration were recorded at the exact time of their occurrence.

MEDICAL MAGISTRATES.—Mr. B. Lumley, M.R.C.S., of Northallerton, has been appointed a magistrate for the North Riding.—Mr. W. D. Spanton, F.R.C.S. Edin., M.R.C.S. of Hanley, has been put on the Commission of the Peace for Staffordshire.

## DEATH CERTIFICATES AND CORONERS' INQUESTS.

AS several cases have recently occurred in which medical certificates of the cause of death have been given unwisely and even improperly, it may be profitable to call serious attention to this very important subject. The lay press, as representing the public, is very severe upon any practitioner who has given a death certificate which subsequent inquiry has shown to be incorrect. Equally severe are coroners, magistrates and prosecuting solicitors. Seeing how very dependent all classes of the public are, for protection from foul play and culpable neglect, upon medical practitioners, from the titled physician to the humble apothecary, this severity is not surprising. But the medical profession may in its turn ask all these severe critics to be just and to take equal cognisance of the following facts and figures. During the year 1890, which was a fairly typical one as regards deaths, the total number of these in England and Wales was, according to the Registrar-General's fifty-third annual report, 562,248. Of these the causes of 514,720, or of 91.6 per cent., were certified by registered medical practitioners. This represents an enormous service rendered to the State quite gratuitously, since the certifying practitioner receives no remuneration whatever from Government. Some practitioners may charge the friends of their patient a fee for the certificate; but this is exceptional, and in by far the larger proportion of cases the medical certification of the cause of death is quite gratuitous. Medical men have therefore no pecuniary motive for giving a certificate of death, as some of these censorious persons imply. It is evidently assumed also by the public that the law which governs the action of the faculty in giving these certificates is so clear and well defined as to present no difficulty. A glance at the Acts will show that this is quite erroneous. The second section of the twentieth clause of the Births and Deaths' Registration Act, 1874, is as follows: "In case of the death of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign and give to some person required by this Act to give information concerning the death a certificate stating to the best of his knowledge and belief the cause of death," &c. Section 3 is: "Where an inquest is held on the body of any deceased person a medical certificate of the cause of death need not be given to the registrar, but the certificate of the finding of the jury furnished by the coroner shall be sufficient." These two sections cover a very large number of cases: (1) those in which there has been medical attendance during life and in which the cause of death is perfectly natural; (2) those in which the coroner is informed of the death by the police, hospital authorities or other informants, and where an inquest follows as a matter of course, a certificate not being asked for. But it must be obvious to many lay readers as well as to all medical readers that the first of the two sections we have quoted is, as it stands, too absolute. Besides the two classes of deaths there is a third, and a very large one, in which the propriety of giving or refusing a certificate of death becomes one of the most important questions with which a medical practitioner has to deal, and upon his decision very serious consequences may ensue. Some physicians have concluded that the Act gives them no power to refuse a certificate in cases where they have attended during life; and in answer to a letter which one of these gentlemen sent some years ago to the Registrar-General that authority upheld this view, observing that the registrars had instructions to refer any doubtful cases to the coroner. With every respect to Sir Brydges P. Henniker we must observe that many cases will from time to time occur in which it is the plain duty of the medical attendant to refuse a certificate, and he will be safeguarded in doing so by Clause 39, which enacts a penalty for refusing a certificate *without reasonable excuse*. Moreover, the medical attendant might urge that he had grave doubts as to what the cause of death was, and that he was unwilling to incur any risk of a penalty under the second section of Clause 40, which punishes with fine and imprisonment anyone giving a false certificate.

Again, different Acts of Parliament must be read not in antagonism to, but in agreement with, each other, and it will be well to give here those portions of the third clause of the Coroners Act, 1887, which ought to guide medical practi-

tioners in giving or refusing certificates of death: "Where a coroner is informed that the dead body of a person is lying within his jurisdiction, and there is reasonable cause to suspect that such person has died either a violent or an *unnatural* death, or has died a sudden death of which the cause is unknown ..... or under such circumstances as to require an inquest in pursuance of any Act, the coroner, whether the cause of death arose within his jurisdiction or not, shall" &c. It is well known that the coroner's right to hold an inquest where an injury is the primary though remote cause of death extends to within a year and a day after the injury. Who but the medical attendant can be aware of such a primary cause, and under such circumstances is it not obviously his duty to refuse a certificate and refer the case to the coroner? Who but the medical attendant can tell whether the death be a natural or unnatural one, whether, if it be a sudden death, the cause is known or unknown, or whether it has taken place under such circumstances as to require an inquest? It is clear from all this that a very large discretionary power rests with members of the profession, and it is obvious that for them to communicate directly with the coroner is a more satisfactory mode of informing him than by giving a certificate with regard to which it is the duty of the registrar not to act, but to inform the coroner. Such a roundabout method can only cause loss of valuable time and great inconvenience.

So far we have dealt with cases in which there has been a medical attendant some time before death. There are, however, other cases where a certificate is asked for. Sometimes a practitioner is called in only to find the patient dying or even dead. In these cases, and especially the latter, it is obviously improper to fill up the usual certificate, and the wisest course is to send a note to the coroner stating the circumstances and leaving it to his discretion as to whether he will hold an inquest or merely make an informal inquiry. Reference to the coroner does not necessarily imply that the case is one of foul play or of neglect. The discretionary powers of that functionary are almost as wide as those of the medical attendant. From the Registrar-General's return already cited we find that the causes of 31,581 deaths, or 5.6 per cent., were certified by coroners after inquest; while the causes of the remaining 15,947 deaths, or of 2.8 per cent., were not certified. These included deaths of infants who had been attended only by midwives, and of persons attended by unregistered practitioners as well as of persons who had received no medical attention of any kind in their last illnesses. In 25,883 cases, or 4.6 per cent. of the total deaths, the cause of death was so inadequately stated that it had to be referred to the class of "ill-defined and unspecified causes." It is satisfactory to learn that the proportion of these was slightly less than in the immediately preceding years, which fact, as the Registrar-General observes, was doubtless in part due to the 3768 letters of inquiry concerning doubtful cases (against 3185 such letters in the previous year) which were sent to the medical men. The result of this process was to transfer a large number of cases from ill-defined to definite headings. Thus, for instance, 522 deaths were removed from more or less vague headings, mainly "tumour," to cancer or malignant disease and 48 to syphilis.

We reproduce these quotations in evidence of our desire to do justice all round and, while guarding our professional brethren from injustice, not to overlook their mistakes. The filling up of a death certificate should be performed with the same care, thoroughness and sense of responsibility as the performance of a surgical operation, the administration of chloroform, or the making of a post-mortem examination. The old adage, "Things which are done in a hurry are not done well," applies especially to the giving of death certificates. In almost all the cases of criminal poisoning in which the deaths were certified to as due to natural causes the certificates had been given hastily and without due thought—in some cases wrongly. In one case justice was defeated by a certificate given by a surgeon who had not attended the deceased during life and who certified that the death was due to stroke. In two other cases certificates were given by a surgeon notwithstanding the strong remonstrances of his partner, entailing consequences upon the certifier which must have been very humiliating to him. A series of deaths from wholesale poisoning by arsenic were certified as due to pneumonia, and the list might be extended *ad infinitum*. Enough has been written to warn all medical practitioners against the hasty or careless giving of certificates.

Should it be considered desirable to amend the Registrar-

tion Act of 1874 it is to be hoped that Clause 20 will have an additional section specifying the cases in which a certificate ought not to be given and thus supplying a great defect. Whether the large discretionary power thrown upon medical practitioners was intended as a compliment is doubtful; that it is a source of much worry, to say the very least, is beyond doubt. Meanwhile in this, as in other matters, members of the profession, individually as well as collectively, will do well to reform from within instead of waiting for pressure from without. Instruction in the matter of giving certificates should form the subject of at least one lecture to students, either in the course of forensic medicine or before the completion of the fifth year of study. Those practitioners who fill up certificates for unqualified practitioners must expect no sympathy from their more right-minded professional brethren, or from the medical press as representing them, still less from the Registrar-General and his superintendents. To young and inexperienced practitioners we would give this advice, Never yield to pressure from the relatives or friends of a deceased person when the propriety of giving a death certificate appears to be doubtful. The refusal may cause some inconvenience or even loss; but these are trifles compared to the humiliation which may result from giving a certificate unguardedly, with the result of having to acknowledge the error in a court of law. We would further remind all members of the profession that it is only to their careful and exact certification of the cause of death in each and every instance that accurate returns can be secured—returns which are of incalculable value to the State, the profession and the public. Still more important is the refusal of a certificate when one ought not to be given, since it is only by this means that the public can be effectually guarded against foul play in its worst form of secret poisoning, and from the many modes in which death may be caused by acts of omission, especially among children of tender age.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Newcastle-upon-Tyne Urban District.*—The death-rate for 1891 exhibited some decrease, amounting as it did to 23·7 per 1000 living; the zymotic rate was 2·5. Measles and whooping-cough were by far the most fatal of the infectious diseases, but neither small-pox nor typhus fever caused a single death, the former disease being at once stamped out, although it made its appearance on three successive occasions. In fact, the means of isolation available for the city and the excellent organisation carried out by Dr. Henry Armstrong afford excellent guarantees for the safety of the inhabitants against any preventable extension of such diseases. Considerable work was done during the year in connexion with the housing of the working-classes, and several departments of the sanitary bureau have been reorganised.

*Lowestoft Urban District.*—On a population of over 23,000 the death-rate last year was 16·2 per 1000 of the inhabitants, the zymotic rate being only 0·3, and the infant mortality 130 per 1000 births. Dr. Wynne has, in short, a satisfactory account to give of the borough, and he is able to speak most hopefully of the diminution which has been experienced as regards cases of enteric fever. Lowestoft is, however, not in a satisfactory state as regards its isolation hospital. The present building is one which is dangerous to convalescents, and its insufficiency has long been known; but the authority still hesitates as to doing its obvious duty in this respect in a proper manner.

*Lowteth Park Urban District.*—Dr. Steeves gives the death-rate of this favoured Liverpool suburb as 13·7 per 1000. The zymotic diseases notified numbered 177, including 123 of scarlet fever, but only 19 cases, of which 13 were scarlet fever, were removed to the isolation hospital. This very small attempt at isolation can hardly be accounted for by the fact that even in such a district the other cases occurred where no necessity for removal arose. It was probably due to the diminutive character of the hospital accommodation available.

*Maidstone Urban District.*—Maidstone had last year a death-rate of 16·7 per 1000 living. Mr. Matthew Adams issues, as usually, a thoughtful and interesting report, in which sound public health teaching is based on a record of local statistics and sanitary circumstances. One portion of the report deals with the London manure nuisance, as to which the Local Government Board are making some comprehensive inquiries through their medical department. He states that again and again have such diseases as diphtheria, erysipelas and septicæmia been attributed to it, and he is strongly of opinion that no excuse exists for casting so gross a nuisance on extra metropolitan districts as is involved in this London manure business. Mr. Adams advocates the automatic waste-water waterclosets for the poorer parts of his district, and he includes in his report some diagrams of the form which he recommends.

*Hanley Urban District.*—Hanley had last year a population of 54,846 and a death-rate of 22·3 per 1000. The zymotic rate was 2·5, and it was largely made up of deaths from measles and whooping-cough. Scarlet fever also became prevalent and efforts were made to cope with it by isolation in hospital and restriction in school attendances, including closure of schools. Mr. John Clare enters at some length into the precautions thus taken. A number of unwholesome tenements and houses have been closed and inspection has been made as to certain trades and occupations calculated to affect public health.

*Bridlington Urban District.*—Mr. W. A. Wetwan reported a death-rate of 19·1 last year, this being an excess largely due to the effects of influenza. The drainage and water-supply are reported as good; but, whilst some improvement has probably been effected as regards scavenging, it is still but imperfectly carried out. Contract work is generally eminently unsatisfactory in this matter, whereas if the authority were to perform the duty themselves there would be no need to discuss whether failure lay with the contractor or with the public themselves. Mr. Wetwan urges a by-law requiring that pig-styes should be at a definite distance from houses. This is an obvious need in many parts of this district, but a similar demand for restricting the keeping of fowls may involve legal difficulties.

*Bridlington Rural District.*—In this district the death-rate for 1891 was 18·8 per 1000. Mr. Wetwan urges increased action and precautions as to cowsheds &c.; he reports the approaching completion of the Flamborough drainage scheme, the need for water in that part of the district, and the desirability of better scavenging and of decent closet accommodation.

*Surbiton Urban District.*—The annual death-rate for Surbiton is given as 13·6 per 1000 for 1891 and the zymotic rate as 1·1. Of the 12 deaths making up the latter rate no less than 10 were of diphtheria, the attacks being a succession of cases spreading over ten months, and it is somewhat cold comfort to be told that the causation was a general one and that the probable reason for the diffusion has to be found in recent climatic and atmospheric conditions, "conditions common to the whole of this island, and indeed the Continent too." Damp, overcrowding and want of ventilation are, however, referred to as local causes, and it is to be hoped these have been dealt with. In all, 21 cases of diphtheria and membranous croup were notified, and Dr. Coleman probably touches the cause of the diffusion most closely where he refers to the inability to distinguish between an ordinary throat affection and mild but infective diphtheria. He suggests that all suspicious cases of throat mischief should be notified; but the danger lies mainly in the cases of those who never come under suspicion at all. The only general sanitary work referred to, apart from the inspector's list, is the thinning out of shrubs round houses, a valuable precaution as regards a town situated in a luxuriant river-valley.

*Wivern Barnet Urban District.*—After giving an account of the infectious fevers prevalent during 1891, the greater number of which were cases of scarlet fever, Mr. Hugh Stott states that the district maintains its ordinary standard of health. He adds that some houses, however, still need a proper water-supply and that sewage from outside the district flows into it and causes nuisance. He also points out the need of by-laws in order to deal with some parts where the soil is waterlogged. The death-rate for last year was only 12·5 per 1000, the zymotic rate being 1·5. For the permanent improvement of the district he urges that the water-supply should be made a constant one, that a disinfecting apparatus and a mortuary should be provided, and that some means should be available for the isolation of first attacks of in-

fectious diseases. If Friern Barnet wishes to maintain a reputation for health and for a low death-rate the sanitary authority should give heed to their health officer's counsel.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6003 births and 3361 deaths were registered during the week ending Sept. 24th. The annual rate of mortality in these towns, which had declined in the preceding three weeks from 19·8 to 18·6 per 1000, further fell last week to 17·2. In London the rate was 15·1 per 1000, while it averaged 18·7 in the thirty-two provincial towns. The lowest rates in these towns were 8·4 in Croydon, 12·4 in Halifax, 12·5 in Wolverhampton and 13·2 in Norwich; the highest rates were 21·9 in Hull, 24·2 in Bolton, 24·4 in Salford and 29·2 in Preston. The 3361 deaths included 605 which were referred to the principal zymotic diseases, against numbers declining from 989 to 747 in the preceding three weeks; of these, 344 resulted from diarrhoea, 58 from diphtheria, 56 from "fever" (principally enteric), 53 from scarlet fever, 51 from whooping-cough, 43 from measles, and not one from small-pox. The lowest death-rates from these diseases were recorded in Croydon, Plymouth, Bristol and Halifax; and the highest rates in Birkenhead, Hull, Salford, Gateshead and Preston. The greatest mortality from measles occurred in West Ham, Gateshead, Salford, Huddersfield and Oldham; from scarlet fever in Nottingham and Huddersfield; from whooping-cough in Nottingham; from "fever" in Huddersfield, Sunderland and Birkenhead; and from diarrhoea in Cardiff, Birkenhead, Sheffield, Leeds, Hull, Gateshead, Newcastle-upon-Tyne and Preston. The 58 deaths from diphtheria included 43 in London, 3 in West Ham and 3 in Birmingham. No fatal case of small-pox was registered in any of the thirty-three towns; two cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 6 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3477, against numbers increasing from 3052 to 3412 on the preceding five Saturdays; 370 new cases were admitted during the week, against 461, 414 and 349 in the previous three weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 114 to 142 in the preceding three weeks, further rose to 152 last week, but were 33 below the corrected average. The causes of 68, or 2·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Oldham, Bradford and in seven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Bristol, Liverpool and Halifax.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the preceding three weeks from 15·7 to 17·0 per 1000, further rose to 17·9 during the week ending Sept. 24th, and was 0·7 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·8 in Dundee and 15·9 in Edinburgh, to 19·0 in Greenock and 21·6 in Leith. The 499 deaths in these towns included 27 which were referred to diarrhoea, 15 to scarlet fever, 14 to whooping-cough, 12 to measles, 6 to "fever," 3 to diphtheria, and not one to small-pox. In all, 77 deaths resulted from these principal zymotic diseases, against 61 and 70 in the preceding two weeks. These 77 deaths were equal to an annual rate of 2·8 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhoea, which had been 24 and 26 in the preceding two weeks, further rose to 27 last week, of which 16 occurred in Glasgow and 4 in Edinburgh. The deaths referred to scarlet fever, which had been 10 and 13 in the previous two weeks, further increased to 15 last week, and included 7 in Glasgow, 5 in Edinburgh and 2 in Leith. The 14 fatal cases of whooping-cough exceeded those recorded in any recent week, and included 6 in Glasgow and 3 in Edinburgh. The fatal cases of measles, which had

been 10 and 12 in the preceding two weeks, further rose to 13 last week, of which 7 occurred in Edinburgh. The 6 deaths from "fever" were within one of the number in the preceding week, and included 2 in Glasgow and 2 in Dundee. The fatal cases of diphtheria, which had increased from 4 to 7 in the preceding three weeks, declined again to 3 last week, of which 2 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 59 and 71 in the preceding two weeks, were 66 last week, and were 14 below the number in the corresponding week of last year. The causes of 33, or nearly 7 per cent., of the deaths in these towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·3 and 23·3 per 1000 in the preceding two weeks, further declined to 19·7 during the week ending Sept. 24th. During the past twelve weeks of the current quarter the death-rate in the city averaged 23·2 per 1000, against 17·2 in London and 16·2 in Edinburgh. The 132 deaths in Dublin during the week under notice showed a decline of 24 from the number in the preceding week, and included 15 which were referred to diarrhoea, 2 to "fever," 1 to scarlet fever, 1 to whooping-cough, and not one either to small-pox, measles, or diphtheria. In all, 19 deaths resulted from these principal zymotic diseases, equal to an annual rate of 2·8 per 1000, the zymotic death-rate during the same period being 2·1 in London and 3·9 in Edinburgh. The fatal cases of diarrhoea, which had been 28 and 18 in the preceding two weeks, further declined to 15 last week. The deaths referred to different forms of "fever," which had been 4 in each of the preceding two weeks, declined to 2 last week. The 132 deaths registered in Dublin last week included 41 of infants under one year of age and 35 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed an increase upon those recorded in the preceding week. Five inquest cases and 2 deaths from violence were registered during the week; and 38, or nearly a third, of the deaths occurred in public institutions. The causes of 16, or more than 12 per cent., of the deaths in the city last week were not certified.

### THE SERVICES.

#### ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel Richard P. Ferguson to be Surgeon-Colonel, vice A. Allan, M.D., deceased; Surgeon-Lieutenant-Colonel Robert C. Eaton to be Brigade-Surgeon-Lieutenant-Colonel, vice R. P. Ferguson (both dated Sept. 6th, 1892).

#### ARMY MEDICAL RESERVE OF OFFICERS.

The undermentioned Officers resign their commissions (dated Sept. 28th, 1892):—Surgeon-Major Charles T. Vachell, M.D., and Surgeon-Captain Charles P. Oliver. The undermentioned Surgeon-Captains to be Surgeon-Captains (dated Sept. 28th, 1892):—John Kerr Butter, M.D., 2nd Volunteer Battalion, the South Staffordshire Regiment, and John Cunningham, M.B., 1st Argyll and Bute Volunteer Artillery.

#### NAVAL MEDICAL SERVICE.

Staff Surgeon Horace Edward Firmin Cross has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet (dated Sept. 3rd, 1892). Staff Surgeon Alfred Thomas Corrie has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet (dated Sept. 8th, 1892). Staff Surgeon William Berkeley Drew has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet (dated Sept. 18th, 1892). The following appointments have been made:—Fleet Surgeon Valentyne Duke to the *Dreadnought* (dated Sept. 13th, 1892). Staff Surgeons: William Tait, M.B., to the *Cleopatra* and Samuel W. Vasey to the *Nelson* (both dated Sept. 21st, 1892). Surgeons: Charles Strickland to the *President*, additional, for three months' study (dated Sept. 12th, 1892); Hugh W. Macnamara to the *Royal Sovereign* (dated Sept. 6th, 1892); Horace B. Marriott to the *Colossus* and George Ley to the *Hotspur* (both dated Sept. 13th, 1892); Herbert P. Shuttleworth to the *Pembroke*, additional, to be lent to the *Briton* for the training season from Sept. 26th (dated Sept. 15th, 1892); James M'C. Martin

to the *Daphne* and Edwd. C. Ward to the *Hyacinth* (undated); and Erington F. S. M'Kay to the *Herald* and Henry E. South to the *Nymph* (both dated Sept. 23rd, 1892); Robley H. Browne to the *Victory*, additional (dated Sept. 29th, 1892); William E. Home, M.B., to the *Swallow*, Cyril J. Mansfield, M.B., to the *Britannia*, and William A. Whiteleggo to the *Volago* (all dated Sept. 28th, 1892).

#### VOLUNTEER CORPS.

*Artillery*: 1st Essex (Eastern Division, Royal Artillery): Surgeon-Lieutenant H. Gurney resigns his commission (dated Sept. 24th, 1892).

#### INDIAN MEDICAL SERVICE.

Surgeon-Colonel W. E. Cates, I.M.S., is permitted to retire from the Service from Sept. 15th, 1892, subject to Her Majesty's approval. The services of Surgeon-Major A. F. Sargent, I.M.S., 3rd Regiment Bombay Light Infantry, are placed at the disposal of the Government for employment in the Civil department. The following gentlemen are appointed to be Fellows of the Madras University:—Surgeon-Major W. R. Browne, M.D., Surgeon, General Hospital, and Professor of Surgery, Medical College, and Surgeon-Major H. Allison, M.D., Fort Surgeon and Professor of Anatomy, Medical College. Surgeon-Major H. K. McKey, Civil Surgeon, Nagpur, is appointed to be in temporary medical charge of the Central Gaol, Nagpur, during the absence of Surgeon-Major T. R. Macdonald on privilege leave.

Surgeon-Colonel Cleghorn, Punjab, has joined the Central Committee of the Lady Dufferin Fund.

Sanction has been accorded to the construction of a new hospital for native troops and followers at Quetta.

The following deaths are reported: George William Powell, retired Honorary Deputy-Surgeon-General, lately residing in Granville-place, Portman-square, died suddenly on Sept. 15th. The deceased joined the Army in 1844, became Surgeon in 1854, Surgeon-Major in 1865, and retired in 1873. Deputy-Inspector-General of Hospitals William Campbell, of Burnside, Ayrshire, N.B., late Bombay Army, died on Sept. 19th, at 2, Manor-road, Folkestone, aged seventy-four.

#### THE PREVALENCE OF VENEREAL DISEASES IN INDIA.

Our contemporary, the *Indian Medical Gazette*, for August contains an ably written article on the remarkably high sick-rate from this cause among the troops serving in all the three presidencies of India. In 1890 no fewer than 34,000 soldiers out of a strength of a little under 68,000 in India passed through the hospital for venereal disease. This our contemporary considers to be nothing short of an alarming state of affairs, demanding the earnest attention of the Government. We have already called attention to the same subject.

#### MOVEMENTS OF MEDICAL STAFF.

The following officers have embarked for India in the *Euphrates*:—Surgeon-Major Peyton, Surgeon-Captains Eckersley, Beach, Gray, Powell, Thurston, Elliot and Jameson. The following officers are returning to India after sick leave and have also embarked in the *Euphrates*:—Surgeon-Major Croly and Surgeon-Captain Markey. Surgeon-Lieutenant-Colonel A. L. Bunne has obtained sick leave from Bombay. Surgeon-Lieutenant-Colonel Barron has arrived in Cork for duty and Surgeon-Lieutenant-Colonel Stannard has assumed charge of the station hospital at Kilkenny. Brigade-Surgeon-Lieutenant-Colonel Comerford has embarked for Bermuda to assume the duties of Senior Medical Officer in the command, and has been succeeded at the Curragh by Brigade-Surgeon-Lieutenant-Colonel Eaton. Surgeon-Captain Gubbin has embarked for Bermuda on a tour of duty. Surgeon-Captain Fletcher has been transferred to Bombay, Surgeon-Captain Wiles to Birmingham and Surgeon-Captain Nunmerley to Hulme. Surgeon-Captains Bartlett and Holyoake have obtained leave from Bombay, and Surgeon-Captain Wade has been transferred to Tregantle Fort. Surgeon-Captain Sexton has been posted to Templemore and Surgeon-Captain Daly to Dublin. Surgeon-Lieutenant Boyts has been transferred from Edinburgh to Netley and Surgeon-Lieutenant Holt has resumed duty at Portsmouth. Surgeon-Lieutenant Stallkart has been transferred from Edinburgh to Dublin and Surgeon-Captain Bell has embarked for a tour of duty in Bermuda. The under-mentioned officers of the Medical Staff, whose tour of foreign service will expire during the troping season 1892-93, will proceed to England in Her Majesty's troopships doing duty with troops during the voyage:—Surgeon-Lieutenant-Colonel W. F. Burnett, Surgeon-Captain R. G. A. Durant in exchange

with Surgeon-Captain J. D. Movi, who exchanged with Surgeon-Captain Hayes; Surgeon-Captain J. W. Buchanan, Surgeon-S. J. W. Hayman, and Surgeon A. R. D. Hall. Brigade-Surgeon-Lieutenant-Colonel H. Comerford, now at the Curragh, proceeds to Bermuda as Senior Medical Officer to replace Brigade-Surgeon-Lieutenant-Colonel J. R. Murray, whose approaching retirement next month we alluded to in last week's issue. Surgeon-Lieutenant-Colonel A. W. Duke, M.D., has arrived home from Gibraltar, and Surgeon-Major J. J. Falvey from India.

#### ASSISTANT PROFESSORSHIP OF MILITARY MEDICINE AT NETLEY.

Surgeon-Colonel E. J. Fairland has been appointed to the above position, vice Brigade-Surgeon-Lieutenant-Colonel W. F. Stevenson, transferred to the chair of Military Surgery in succession to Surgeon-Colonel Godwin. He joined the Army April 1, 1867, and served in the Abyssinian campaign of 1867-68 (medal).

#### THE SANITATION OF BOMBAY.

It appears that sanitary appliances of English design are not altogether adapted to the requirements of a city like Bombay or to the habits of its people. The corporation of Bombay recently appointed a committee to inquire into the working of house connexions with sewers, and it has now completed its researches. What with narrow streets and gullies, the overcrowding, heat and exceptional climatic conditions, the problem is not an easy one. Still a practical solution of the problem will no doubt be arrived at in the course of the experiments that have been decided on.

#### DEATHS FROM CHOLERA.

The deaths of Surgeon-Colonel Allan, the administrative-medical officer of the Rawal Pindi Division, and of Surgeon-Captain Kenny, which we recently announced, took place at Murree from cholera. It appears that the disease had broken out at Gharial, near Murree, where the Seaforth Highlanders are stationed, and that the above-named medical officers were among the first fatal cases.

#### BOY VOLUNTEERS.

Sir Evelyn Wood, V.C., is unquestionably one of the most indefatigable and energetic of our general officers. He had only just returned from Germany when he addressed a letter to the masters of all the public schools which had sent parties to join the Volunteer battalions encamped for training at Aldershot in July last. It seems that 440 boys were encamped near Aldershot in 1891, but last July fourteen schools sent up boys and 590 were encamped in one of the fields near Government House. The General says the boys' conduct was exemplary, their health was excellent, there was no sickness or casualties of any kind, and the messing arrangements were good. No doubt the boys liked the outing, and the training did them good and they were well looked after. Sir Evelyn Wood evidently considers this yearly camping out as a capital thing physically and morally for the boys, to say nothing of their acquiring a knowledge of drill and a sense of discipline and obedience which will do them no harm later on in life.

#### OUR SOLDIERS' FOOD.

Sir Evelyn Wood has manifested much zeal in the soldier's welfare, and especially as regards his feeding. Until quite recently the best was not made of the soldier's rations and groceries, and but little was known as to the means necessary to decide on the quality of the provisions supplied him. The importance of the stock-pot, which exists in the kitchens of most of our households, had not been recognised, whereas under the new system it is, and the food is both varied and well cooked and there is no waste. The soldier of to-day is probably better fed than he ever was before, provided his regiment has had the good fortune to secure the services of a cook thoroughly trained at Aldershot, and to possess officers at the same time who are interested in the subject. One officer from each regiment quartered at Aldershot has been ordered to attend a course of instruction in judging the quality of provisions intended for the soldier's consumption. The object of army hygiene is to keep the soldier out of the hospital, and this is one excellent way of doing it.

#### THE ACQUIREMENT OF THE RUSSIAN LANGUAGE.

The new regulations that have been published in India regarding the acquirement of the Russian language apply to officers of the Indian Army and of the Indian Medical Staff. These regulations lay down the terms for officers visiting-

Russia with reference to service towards promotion and pension and furlough regulations. Officers permitted to proceed to Russia from India who may succeed in qualifying as interpreters, will receive a gratuity of £200 and a further sum of £20 towards the cost of the journey to Russia, plus half of the consolidated sum of £32 or £42 which is allowed to officers who have proceeded from England for travelling expenses to and from St. Petersburg or Moscow, as the case may be.

#### WORK FOR THE NEW WAR MINISTER.

Our service contemporary the *Broad Arrow and Naval and Military Gazette* directs attention to the matters which will probably be pressed upon the consideration of the new Secretary of State for War. Our contemporary is quite right in stating that the alteration of the regulation regarding the extended length of foreign service is the most important subject. The present regulations press heavily upon officers of the medical staff in the matter of health, and the length of foreign tours of service should, in our opinion, be reduced to what it was before the order for prolonged tours abroad came into force—viz., the term of continuous service abroad should not exceed five years, as recommended by Lord Camperdown's Committee. The amalgamation of the Army Medical Staff and Medical Staff Corps into a "Royal Medical Corps or Staff" is a reform that we have also always advocated, and it was recommended by Lord Morley's Committee.

#### SCIENTIFIC RESEARCH.

The Government of India have recommended that Dr. D. D. Cunningham, of the Indian Medical Service, who is Professor of Physiology in the Medical College, Calcutta, be given two more years in which to complete his scientific observations. It is well known that he has been engaged for a considerable time past in investigating the origin of cholera, with special relation to the bacillus theory, and it is alleged that his most recent researches on the comma bacilli in cholera are highly important. If so, the publication of his observations, as far as they have extended, would be very valuable at the present time.

## Correspondence.

"Audi alteram partem."

### THE NOTIFICATION OF DISEASE.

To the Editors of THE LANCET.

SIRS,—I quite agree with Dr. Goodhart that the point he raises "is an important one to a large section of medical men." The case he refers to was a fatal case of diphtheria, the first intimation of which I received in the mortality return supplied to me by the district registrar. I of course at once made inquiries, found that three medical men had been "attending or called in to visit the patient," and wrote to them to ask why they had not certified the case to me. On receiving replies which satisfied me that there had been no intentional concealment of the case I reported to this effect to the sanitary committee, who decided at my recommendation to take no action in the matter. Dr. Goodhart seems to think that only one medical attendant is required to certify a case, and that he was not that one. The words of the Act are, however, perfectly clear: "Every medical practitioner attending on or called in to visit the patient, shall forthwith, on becoming aware that the patient is suffering from an infectious disease to which this section applies, send to the medical officer of health of the district a certificate stating," &c. As a matter of fact, if several medical men see a case and only one certifies it to the medical officer of health, the latter is quite satisfied, as he does not want more than one certificate of one case; but if neither of them certifies it he is bound to report them all to his committee as delinquents. Dr. Goodhart says, "I was further politely informed that as I had sinned in ignorance no action would be taken on this occasion—in other words, I must not be a bad boy again or I should receive a whipping."

In this I think he exactly describes the position, and as he has made it publicly known that he has neglected to certify a case of diphtheria which proved fatal my friendly advice to him is that he should take very great care to certify

any case of "notifiable" infectious disease that he may attend or be "called in to visit" in future.

I am, Sirs, yours faithfully,

W. H. CORFIELD, M.A., M.D. Oxon.,  
Medical Officer of Health for  
St. George's, Hanover-square.

Savile-row, W., Sept. 27th, 1892.

### FRACTURE AT THE SYMPHYSIS PUBIS WITHOUT INJURY TO BLADDER.

To the Editors of THE LANCET.

SIRS,—The following may interest some of your readers. Some years since, when practising in Yorkshire, I was sent for to see a man (J. W.—, aged forty); while sitting in a swing lowered down the face of a rock, working for stone, the rope broke and he was thrown down a great height, falling flat on his abdomen. I examined the man and found nothing wrong, except fracture at the symphysis pubis, the bones overriding one another. I had him placed in bed and passed a broad firm bandage round his body. He lay perfectly still for four weeks, and in twelve weeks was again at his work as a quarryman. One hour after his fall, to my great relief, he passed a good quantity of urine. On inquiry he told me that he emptied his bladder just before he got into the swing, thereby preventing rupture of the organ and saving his life. If men so engaged would only micturate before going up heights for similar work, many a life might be saved, as in J. W.—'s case.—I am, Sirs, yours truly,

H. J. RICE, L.R.C.P., L.R.C.S. Edin.

Sandbach, Cheshire, Sept. 24th, 1892.

### "THE MIDWIVES' REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—Mr. Rowland Humphreys' letter in THE LANCET of last Saturday may in the opinion of many of your readers require a reply from me, for your correspondent calls attention to what he thinks are "some errors I have fallen into." I did not forget that there was a delusive clause in the late Midwives' Bill by which a proof of a certain amount of knowledge was required before registration, but that it was a fair amount I certainly did not know and deny. The midwife's answer to the coroner, "that she had acted as a midwife for twenty years, and that as far as she knew she had never had anything amiss with any patient she had attended," would have been sufficient reason, had the Bill passed, to have placed her on the register of qualified midwives, and I too feel equally sure that her not wilful ignorance would also have been a sufficient reason with the jury to have prevented any punishment following her most reprehensible inaction and the lamentable result of her culpable, although not legal, ignorance. Your correspondent states that it might be desirable, as I suggest, that no midwife should be allowed to act except under the eye and the responsibility of a medical man, but adds, "who is to pay them? for it would be quite impossible for doctors to do all the cheap work thus thrown on them and live on the results." I differ from Mr. Humphreys. I think there are not only in London but in every town medical men who would not object adding to their daily list two or three or even half a dozen of such obstetric calls, and if the patient was too poor to pay for these needed visits the moderate fee of 2s. 6d. per visit should be defrayed, if a parish case, by the guardians, and if private, by the club or some such society as the London and Manchester, or other kindred society which provides medical aid for the industrial classes, and a very slight increase to their present very low rate of weekly payment would be sufficient. I should make my letter, even for a reply, too long did I enumerate the need and advantages and the saving of life that would result from these visits of the qualified practitioner (where a midwife had attended), who would see that the labour was progressing satisfactorily and that the convalescence was neither retarded nor prevented by dangerous or unusual symptoms; but assuredly it was far from my intention that the doctor should "bear" or even cover the misdeeds of the midwife or obstetric nurse, but on the contrary to prevent them. I opposed the late Bill because it appeared somewhat crude and unsatisfactory, but I admired the principles and desires that gave it birth, and from its ashes I look hopefully for such ripe legislation that will ensure increased safety and lessened suffering to the mothers of the poor and, at the same time, and not unmindful

of the interest of the general practitioner, who, like other toilers, lives by the sweat of his brow and is not unworthy of his hire. I am, Sirs, yours obediently,

FREDERICK H. ALDERSON, M.D.

P.S.—In the absence of some system of State medicine for our artisans and industrial classes such societies, as the London and Manchester, which provide medical aid by weekly payments, have become a necessity.

Hammersmith, W., Sept. 27th, 1892.

## "PSYCHO-THERAPEUTICS."

To the Editors of THE LANCET.

SIRS,—Dr. William Dale, commenting in your last issue on Dr. Robertson's interesting article on "Psycho-therapeutics," makes, I consider, a somewhat unfair attack upon hypnotism by asserting that it is "merely another form of the miserable farce which, under the name of mesmerism, wrecked Dr. Elliotson's reputation." The physiology of the nervous system was comparatively so little understood fifty years ago that we cannot wonder that Dr. Elliotson was unable to grasp the real causation of so-called mesmeric phenomena, and that, failing the possibility in the then existing condition of knowledge of giving a rational explanation to the effects he witnessed, he endorsed the prevalent theory of animal magnetism. There is no doubt that he lost his head, and by allowing himself to be duped by clairvoyants and spiritualists he injured his reputation. Now things are widely different, and modern research has enabled recent scientific exponents of hypnotism to place the practice of hypnotic suggestion on a rational basis. Whatever may be the opinion of individual practitioners as to the value of therapeutic hypnotism, everyone must admit that the study of suggestion by such masters as Charcot, Bernheim, Preyer and Tamburini has immensely added to our knowledge of psychology and offered us a key to the understanding of the action of the mind on bodily conditions and functions. The study of suggestion, with or without hypnotism, will help the physician to cultivate that "tact and personality" to which your correspondent attaches so much practical importance in the combating of disease. It seems to me somewhat unfair that the question of the value of hypnotism should be treated in the offhand style adopted by Dr. Dale, and I think he will modify his wholesale condemnation of the practice of hypnotic suggestion if he will study some of the recent literature on the subject and will apply the knowledge thereby gained to the treatment of a few properly selected cases.

I am, Sirs, yours obediently,

CHAS. LLOYD TUCKEY, M.D. Aberd.

Green-street, W., Sept. 25th, 1892.

## "DRUNKENNESS AMONG WOMEN."

To the Editors of THE LANCET.

SIRS,—In your issue of to-day in a short annotation, you say "no one who has his eyes open can fail to see that women are fatally losing modesty in the way in which they enter public-houses." This is very deplorable, but it is far sadder to observe that the facilities for obtaining stimulants afforded by the grocer's and confectioner's licence necessitate no violence to the sense of female propriety, and young girls or older women who would shrink from the door of a public vault complacently sit and chat over a biscuit and glass of wine, or sandwich and glass of ale, in these shelters, which, terrible to contemplate, have proved a *facilis est desoensus Avorni* to many.

I am, Sirs, yours truly,

JOHN DRUMMOND, L.R.C.P. Edin. &c.

Malvern, Sept. 24th, 1892.

## VACCINATION STATISTICS.

To the Editors of THE LANCET.

SIRS,—With reference to the suggestion in THE LANCET of the 24th inst., that the evidence obtained in the four fatal cases of adult hæmorrhagic small-pox which occurred last year in Birmingham may not have been "unequivocal," permit me to explain that I took the precaution of obtaining evidence in writing before I wrote to *The Times* on the subject. As to the placing of these fatalities among the "unvaccinated class," I understand that they would

go into the "not stated class," although in two of the cases it was well known that they had large, deep marks of vaccination. As this neglect has been shown to exist widely, it is obvious that no arguments can safely be drawn from the Registrar-General's statistics in favour of vaccination; and the fact that our medical officer of health refused to help me in tracing the relatives by giving me the addresses of the fatal cases leads, not unjustly, to the inference that the omission to enter the true facts, as required by the Registrar-General on the death certificates, is not always accidental. Whether nowadays "the mere fact of vaccination having been performed at all is considered by the profession to be absolutely protective against fatal small-pox during the whole of life" or no, it cannot be denied that it was on an assurance that it was thus absolutely protective that the compulsory law—which so nearly concerns us guardians—was passed. But if the new claim be now accepted that "vaccination, efficiently performed and reinforced by revaccination, is—in the healthy—almost absolutely protective against the ravages of small-pox," then we guardians have to consider the notorious fact that sanitation without vaccination in the Leicester and Keighley Unions is also "almost absolutely protective." In the latter town it is protective even without isolation. Therefore—even conceding, for the sake of argument, and against the evidence of Mr. Farn before the Royal Commission, that guardians are able to ensure that vaccination can be "efficiently" performed, and that a man sickened with cow-pox can be "healthy"—the at least equally efficient Leicester and Keighley plan commends itself to a guardian as cheaper and less risky than the system which failed to keep small-pox out of well-vaccinated but insanitary Sheffield in 1887. If "year by year in this country the numbers of the unprotected are increasing" and small-pox is on the whole decreasing, then the "protection" and the immunity are in inverse proportion to one another, and the latter cannot be due to the former, but to some other cause, probably to better sanitation.

Lastly, permit me respectfully to protest against your terming me a "prejudiced inquirer." As a guardian I am compelled by my duty to the poor and the ratepayer to investigate this question. If after careful inquiry I am driven to accept the conclusions of Dr. Creighton and Professor Crookshank, why should the intellectual process expose me to this aspersion? I feel it the more from THE LANCET, because that journal has not yet itself seriously controverted the facts and arguments of those scientists.

I am, Sirs, yours faithfully,

A. PHELPS,  
Major-General, F.S.S.

Edgbaston, Sept. 27th, 1892.

\* \* \* The views upon this subject held by our correspondent are so utterly at variance with our own that it would be useless to waste time and space in discussing them. We must agree to differ. We would, however, point out that it will be long before sanitation has driven away all infective diseases, including small-pox, from our midst; and that even the vigilance of Leicester and Keighley may some day be surprised by an outbreak in which it is certain that the people unprotected by vaccination will suffer cruelly; moreover neither Dr. Crookshank nor Dr. Creighton has *proved* that vaccination is of no efficacy.—ED. L.

## THE LOCAL GOVERNMENT BOARD AND THE ROYAL COLLEGE OF PHYSICIANS

To the Editors of THE LANCET.

SIRS,—Some misapprehension seems to have arisen as to the correspondence which recently passed between the Local Government Board and the Royal College of Physicians; and it is in the main due, I think, to the circumstance that the letter which the Secretary, Sir Hugh Owen, addressed to the College, and which you published on the 17th inst., has not been carefully read. The letter relates to that which would become necessary provided regulations as to cholera had to be issued under the Public Health Act, 1875. Section 133 of that Act, following the lines of the old Diseases Prevention Act, empowers local authorities "themselves to provide or to contract with any person to provide a temporary supply of medicine and medical assistance for the poorer inhabitants of their district"; and Section 134 allows regulations to be made,

amongst other things, "for the provision of medical aid and accommodation."

You rightly say that it is the "sick poor" who will mainly need assistance; it is this which regulations under the Act contemplate by the use of the words "poorer inhabitants." You properly say that early medical attendance and nursing are as essential as medicines. Cholera regulations under those sections always require the local authorities to provide a special staff of medical visitors and of nurses for the purposes of a house-to-house visitation such as you also advocate; and such intervention is only "until other provision for [the] medical attendance" of the sick is made. The letter addressed to the College had no need therefore to refer to these requirements, which are already met. But there remained "the supply of medicine" which the Act required the local authorities to provide without charge for distribution by their medical visitors and at dispensaries, to be open day and night, for such "immediate medical treatment" as the regulations specified. It was as to this supply by town councils, local boards &c., of "medicines," together with any necessary medical appliances, that the Local Government Board asked the College of Physicians to advise them, and through them the local sanitary authorities of England and Wales. And for reasons which are thus quite obvious, they asked nothing more than this.

I am, Sirs, yours faithfully,

Sept. 26th, 1892.

PUBLIC HEALTH.

### ISOLATION IN BOOTLE.

To the Editors of THE LANCET.

SIRS,—Your reference to my action, at our recent council meeting, in opposing a proposition to erect a pavilion for the treatment of diphtheria, being based upon erroneous statements, I wish to give the facts of the case and to explain the cause of my opposition.

The fever hospital here was opened only six years ago, having been built under the supervision of the late Alderman Matthew Hill, M.D., consulting physician, according to plans approved of by the Local Government Board. The then chairman of the health committee, Alderman Williams, confirms the fact, which I already understood, that complete arrangements had been made in the Western Pavilion for the separate treatment of cases of diphtheria; and the medical officer of health, referring to the fever hospital in one of his annual reports, says: "Bootle need not now, as in former years, fear the outbreak of any epidemic." Feeling confident, therefore, that ample provision had already been made for diphtheria, I opposed the erection of a pavilion for those cases. There was no truth in the statement that a diphtheria patient was taken into the hospital, caught the fever and died. The chairman now admits that he made a mistake, and the resident medical officer denies that a case of diphtheria has ever been treated in the wards along with any other disease. The statement that a fever patient, while under treatment in the hospital, contracted diphtheria and died is not supported by any evidence; in fact, there is no record in the medical officer's published annual reports of any death from diphtheria having occurred in the hospital since its establishment.

I am, Sirs, yours faithfully,

Bootle, Sept. 28th, 1892.

T. M. WILLS.

### "THE STAMPING OUT OF GLANDERS."

To the Editors of THE LANCET.

SIRS,—In one of your annotations on Sept. 17th satisfaction is expressed that more enlightened and efficient regulations are about to be enforced against glanders. I should be very glad to think so, but all that the Board of Agriculture can do under the existing Act of Parliament is to issue an Order permitting local authorities to be more efficient. There has been twenty years of permissive legislation for the diseases of animals, but no success has ever attended it; only when compulsory enactments have been made has success followed. I sincerely hope that those who know something of glanders and of the working of the Contagious Diseases (Animals) Act will speak out on this rumoured attempt of the Board to refurbish up their old weapons—weapons their advisers have so often described as inefficient. The last paragraph of your annotation says: "So long as horses are permitted to come from infected regions we shall always be liable to its introduction." This is true, not only of foreign countries,

but of our own island. If we stamp out glanders in Edinburgh and leave it alone in Glasgow, Scotland is not likely to remain free. If we stamp it out in London and allow it to exist in Birmingham we shall have to continue the work in England *ad infinitum*. A permissive order is not what is wanted. An amendment of the Act is a *sine qua non* to stamp out the disease. There are, I believe, thirty infected counties, and unless the disease is attacked in each district at the same time and in the same manner it will disappear in one place only to arise again by the introduction of horses from infected places. London is the great centre of the disease, and if the County Council is not afraid to spend the money of the ratepayers it will undoubtedly reduce the disease in a few years to a very small bulk. It must be remembered, however, that the five surrounding counties are all infected, and that until all their diseased horses have been killed or brought into London occasional reinfection must be expected. There is, as you say, "no great difficulty in combating the disease," but that depends on general and uniform measures being adopted over the whole country—a course which can only follow an amendment of the Act. Therefore the first step should not be made until Parliament meets.

I am, Sirs, yours truly,

JOHN ATKINSON, F.R.C.V.S.

Sept. 20th, 1892.

\*\* We quite agree with our correspondent as to the absolute necessity for general and uniform measures being applied to the extinction of glanders, and that these should be compulsory. It will be the business of Parliament to deal with this question, and in a comprehensive and enlightened spirit. Leaving the malady to be handled by the local authorities is simply losing time, throwing away money and causing needless embarrassment to horse owners. The amendment of Acts of Parliament applicable to the contagious diseases of animals should have been undertaken by the Board of Agriculture long ago, as glanders is now, by all accounts, widely prevalent.—ED. L.

### MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

#### *Hospital Extension: Clinical Hospital, Cheetham Hill-road.*

FOR many years past the work of this excellent charity has been impeded by reason of the cramped and otherwise unsuitable character of its administration. The out-patient department has hitherto been placed too close to the wards of the hospital, and as a consequence there is serious and constant danger that various kinds of infection may get transmitted from without to the surgical patients under treatment in the hospital, to the no small risk of the latter. To remedy this defect a new administrative block has just been completed, which, although conveniently situated for central administration, is nevertheless far enough removed from the hospital proper to render almost impossible the extension of infection from the out-patients to the occupants of the surgical wards. The new out-patient department forms a handsome structure facing the Cheetham Hill-road, and adjoining the Jewish synagogue. It consists of a large and commodious waiting-room, with smaller rooms for consultation and convenient offices for dispensing and for the performance of minor operations. The building has been erected at a cost of about £2000, on a site presented by the trustees of the late Mr. Daniel Proctor.

#### *New Cancer Hospital.*

Stanley House, a large and well-appointed residence on the Stanley Grove estates, recently presented to the Owens College by the Whitworth trustees, has now been considerably altered and adapted to the purposes of a hospital for about forty cases of malignant disease. The building stands in its own grounds, which are picturesque and very pleasantly situated, and will form a hospital which may be considered fairly accessible to the population of Manchester and the surrounding district. The Stanley House Hospital is intended to form the nucleus of a much more extensive establishment to be eventually provided on this estate for the equipment of our great school of medicine. The hospital will doubtless be utilised for teaching purposes, as well as for purposes of original research, by the medical staff of Owens College.

*Monsal Hospital.*

According to newspaper reports of the last meeting of our council, the representatives of Newton Heath are much concerned at the considerable extensions that are now apparently being pushed forward at the Monsal Hospital, which is within the Newton Heath township of the city. On inquiry, however, it turns out that the authorities do not at present contemplate the extension of the permanent hospital accommodation at Monsal. The complete separation, however, of small-pox from fever at the hospital is now being asked for by the city corporation, and accordingly an attempt is being made to accommodate each disease in a separate and distinct hospital, space being provided within the small-pox hospital enclosure for temporary extension, in the event of epidemic prevalence of that disease. The two large wooden pavilions which were recently built for the isolation of cholera patients in case of necessity will probably form sufficient means of dealing with such limited outbreaks of small-pox as are likely to require hospital provision in ordinary non-epidemic times.

*Refuse Disposal.*

In view of the recent enlargement of the city and of the increase in the amount of night soil which consequently requires removal, the cleansing committee of our corporation find themselves confronted with a similar difficulty to that with which they had to deal a few years since when, in consequence of a considerable enlargement at that time of the municipal boundaries, it was found necessary to acquire the Carrington Moss estate, and to convey thither such portions of the excretal refuse of the city as could not be converted into pondrette or "bag manure" as it is locally termed. When regard is had to the circumstance that by the City Extension Act of 1890 the area of Manchester was just doubled and its population increased by more than a third, it will readily appear that the limited acreage of Carrington Moss has now become insufficient to cope with existing requirements. In this dilemma the cleansing department have, after diligent search, eventually succeeded in securing an estate 1800 acres in extent at the village of Rampton in Nottinghamshire, to which they propose to send 20,000 tons annually of the midden refuse, for the disposal of which they have now accepted the responsibility. On Tuesday last Mr. Joseph Smith, engineering inspector to the Local Government Board, held an inquiry at the Manchester Town Hall with reference to an application by the city corporation to borrow £60,000 for the purchase of the Rampton estate. At this inquiry, and again at the adjourned inquiry, which took place at Rampton on Thursday last, considerable opposition was shown to the scheme on the ground that much local nuisance, as well as pollution of the watercourses, would accrue as the result of the proposed operations. The inquiry has been still further adjourned to Wednesday next, when further evidence will be heard at Retford, a neighbouring town, which is conveniently situated for the purpose. The inspector will probably complete his inquiry on Wednesday, and both parties to the suit are naturally anxious that the Local Government Board should lose no time in communicating to the City Council their decision on a question which is of very much more than local importance.

Sept. 27th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

*Newcastle Hospital Sunday Fund.*

THE annual meeting of the Newcastle Hospital Sunday Fund, which has now reached its twenty-second year, has just been held. The report showed that last year £4744 had been collected, being the largest sum yet recorded. There was a decrease, however, in the amount received from factories &c.; but the committee explained that this did not necessarily mean that the contributions of the workmen were falling off, as weekly and fortnightly collections were made at many places, which the workmen forwarded directly to the medical charities in which they were interested. The expense of managing the fund was just  $7\frac{1}{2}$  per cent., an outlay so small as to be scarcely equalled by any other fund of the kind with collections extending over such a large area. The committee aim at the future collections reaching £5000 per annum, and they would, it seems, appear to be gradually working up to that amount.

*Fatal Carriage Accident to a Surgeon.*

A very sad accident has occurred to Mr. R. C. Richards, M.R.C.S., of Shotley Bridge, Durham, which cost him his life. Mr. Richards, with two friends, was driving in the city of Durham on Wednesday, Sept. 21st—a dark night—and not being acquainted with the streets, which in many places are dark and narrow, the vehicle came in collision with some railings and he and his friends were thrown out. Mr. Richards sustained a fracture of the skull with concussion of the brain. He was removed to the Durham County Hospital, where he died in a few hours. The coroner at the inquest said the accident was distinctly traceable to the misplacement of the lamps, and the jury, in their verdict of "Accidental death," added a rider to be sent to the Durham corporation advising the fixing of a lamp at these dangerous railings to warn drivers and others.

*Want of Ventilation and Bad Air.*

At a late meeting of the Jarrow Sanitary Committee a discussion took place on the prevalence of measles. The medical officer was empowered to close the Ellison Schools for two months. It was submitted by a member that if the schools in the town had proper ventilation these continued outbreaks of epidemic disease would not arise; the infant schools, it was stated, were in many cases overcrowded with children from three to six years of age. At Gateshead an inquest has been held on a boy aged six years and a half, who died from syncope, a fatality which would appear to have been caused by foul air. An assistant teacher said she was engaged in opening a window for ventilation when she heard a noise and saw that the little boy had been very sick. She carried him outside and sent for medical aid, but he died almost immediately. An inquest has been also held at Walker touching the death of a young man named Bandon, aged eighteen, a well-known cyclist. It was proved that he died from suffocation when taking a hot bath heated by gas, and that he had made an attempt to save himself by running off the hot water. The bath, it was shown, had been fixed only the previous day, and the deceased was the first person to use it.

*The Proposed Lunatic Asylum for Middlesbrough.*

A committee appointed by the Middlesbrough corporation was engaged last week in inspecting the various sites which had been suggested for the proposed lunatic asylum for Middlesbrough.

*Munificent Gift to Cumberland.*

Mr. Simmond, a wealthy resident of Southport, has announced his intention of giving the county of Cumberland £20,000 for hospital purposes, £1000 of which is to be used for the building of a cottage hospital at Penrith.

Newcastle-on-Tyne, Sept. 23th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Insanity: its Causes and the Question of Increase.*

IN the third annual report on the Certification of Lunatics in the Barony Parish, Glasgow, Mr. Carswell, the certifying physician, makes some remarks of more than usual interest. Dealing first with the supposed increase in insanity, he states that there is no evidence to show that this condition is becoming common. It is true that there has been an increase in the number of applications for admission to the parochial asylum and a small increase in the number actually certified and admitted; but the cause or causes of this have nothing to do with any actual increase in lunacy or even possibly of nervous diseases. It seems that persons suffering from delirium tremens, hysteria and various states of excitement and stupor are reported to the inspector of poor, who is supposed to have facilities at his command for dealing with such cases. These patients are troublesome at home; general hospitals do not receive them, or do so only after formalities preventing immediate removal. Whether these transient disturbances of the nervous system are on the increase or not there can be no doubt that there is now greater readiness on the part of the public to avail themselves of the advantages of public institutions, and Mr. Carswell is inclined to ascribe to the latter consideration any increase in the number of lunacy applications to the inspector of poor. Mr. Carswell thinks there is no reason for supposing that insanity is increasing, but points out the danger

of medical opinion regarding the certification of lunatics becoming conformed to the pressure of public sentiment. Opinion, he says, has shown a tendency to expand in regard to the degree of mental disturbance which requires asylum treatment; and this opinion he says has come about chiefly as a part of a general social movement towards relieving individual persons of unusual or special burdens at the public expense. Mr. Carswell refers to a desire on the part of the profession for some provision whereby temporary care may be secured for the transient forms of nervous disease and a better basis obtained for the certification of lunatics. This has been attempted at Barnhill Hospital by the establishment of wards where special supervision is exercised over cases of a temporary nature, an arrangement under which it becomes possible to make a diagnosis of a definite form of insanity requiring asylum treatment, and to make this the only ground on which a person is certified as insane. The value of such wards is seen in the fact that there were treated in them in the past year 99 cases of non-certifiable disorder, the total for the past three years being 238. During last year there were 345 persons reported to the inspector of poor as insane; of these, 192 were at once certified and removed to an asylum. Of the 153 doubtful cases remaining, some were dealt with by other parishes, some by friends, while 105 were sent to the wards at Rainhill for temporary treatment and watching; of these 105, only six were afterwards certified, the remaining 99, as above noted, requiring only temporary care. The importance of such probationary wards is thus manifest. Mr. Carswell states that the one outstanding fact illustrated by the statistical tables is that insanity is the result of various diseased or abnormal conditions of brain and nervous organisation and function, due to (a) inherent defects of brain and nervous organisation; (b) to degenerative diseases of brain structure; and (c) to diseased states of the blood-supply to the brain. All these diseased states of the organ of mind may be prevented just as, and only as, diseased conditions of other organs are prevented, by due regard to the ordinary laws of health. Unwise marriages, imprudence and intemperance in conduct, and unhealthy conditions of living generally produce insanity, just as the same conditions in other subjects produce phthisis and other similar diseases. It is a common error to suppose that a large amount of insanity is caused by the high pressure of modern life, modern educational methods and so on. It is well that people should understand that the real causes are nearer their own lives and conduct, and therefore are more entirely under their own control, than is commonly supposed.

#### Health of Aberdeen.

Fever is on the increase in Aberdeen, 66 cases of measles and 40 of scarlet fever having been reported last week. The City Fever Hospital is full and large numbers of cases have to be refused admittance. The preliminaries for extensive additions to the hospital, to cost £12,800, are being pushed rapidly forward.

#### Aberdeen Royal Infirmary.

The new surgical pavilion of this hospital is now completed and ready for use. It contains accommodation for 145 patients, the wards being situated on three floors, and comprising 6 general wards, 2 eye wards, 2 lock wards, 1 ward for diseases of women and several isolation rooms. On the ground floor are two large operating theatres, the ophthalmic department, the directors' room and offices for the clerk and treasurer. A separate block contains an excellent post-mortem theatre. Electric light is used throughout. The buildings are to be honoured by a visit from Princess Louise, Marchioness of Lorne, and the Duke of Connaught on Oct. 4th, when the Princess will formally open the wards. With these wards in use it will be possible to transform the old building into an administrative block, which, with the medical pavilion to be built next year, will complete the infirmary.

#### Professor Ogston.

The announcement that Dr. Ogston has been appointed one of Her Majesty's Surgeons-in-Ordinary for Scotland was received with high approval as well by the laity as by the medical profession in the north of Scotland. Dr. Ogston had the honour of being received by the Queen at Balmoral on his appointment.

Sept. 27th.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

#### Vice-Regal Appointments.

THE following appointments, it is stated, have been made by His Excellency Lord Houghton:—Physician-in-Ordinary, C. J. Nixon, M.D. R. U. I.; Surgeons-in-Ordinary, R. F. Tobin, F.R.C.S.I., and Arthur Chance, F.R.C.S.I.; Surgeon-Oculist, A. H. Jacob, M.D. T. C. D., F.R.C.S.I.

#### Precautions against Cholera.

The Cork rural sanitary board, having received an offer of a hulk from Sir J. Arnott for the purpose of a floating hospital for cholera patients, Mr. Hodges, with Surgeon-Lieutenant-Colonel Barry and others, made an inspection in order to select a vessel for the purpose. They have reported that the *Mont Blanc* was admirably suited for a hospital of the kind. The deck space is about 150 ft., with a breadth of 24 ft. inside the bulwarks, allowing ample accommodation to construct a hospital ward 60 ft. long by 24 ft. wide. In addition there will be 45 ft. aft of the hospital ward which can be utilised for medical attendants and nurses' quarters, kitchen, dispensary, disinfecting chamber &c. The intercepting hospital will be used for small-pox and other infectious diseases. The Drogheda guardians have placed an iron hut, to serve as an intercepting cholera hospital, near the Maiden Tower, at the mouth of the Boyne. The people in the vicinity have, however, expressed their hostility to the project, and the hut has been guarded by police night and day to prevent its threatened destruction. A memorial has also been sent to the Local Government Board asking for its removal, but the Board have replied that the temporary cholera hospital will be maintained, no matter at what risk or cost. The military authorities at Waterford have asked the guardians in case the cholera broke out in that city if they would set apart a room in their cholera hospital containing eight beds, with a nurses' room adjoining, for the reception of soldiers who might be attacked with the disease. The guardians have unanimously refused to provide separate hospital accommodation for soldiers, on the ground that it was the duty of the military authorities to make the necessary arrangements to treat soldiers attacked by the disease.

#### Wanderings of a Needle.

A woman named Margaret O'Grady about two years since accidentally swallowed a needle and last week complained of a disagreeable sensation in her shoulder. On examination at Mercer's Hospital it was found that the pain was due to the needle, and it was extracted without difficulty.

#### Insanitary Condition of Coolstown Courthouse.

Last week the revising barrister adjourned the sessions *sine die*, or until the building shall have been placed in a proper sanitary condition. Since then the work of correcting the voters' list has been carried on in another building.

Mr. A. E. Wynne, late house surgeon to Mercer's Hospital, has been presented with an illuminated address and a purse of sovereigns.

A woman named Cassells died yesterday at Warrenpoint at the reputed age of 108 years.

Sept. 27th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### Subcutaneous Injections of Thyroid Extract as a Remedy for Myxœdema.

THE belief in the importance to the animal economy of the presence in the normal state of such bodies as the thyroid, supra-renal capsules &c. is steadily gaining ground in this centre of medical activity. That organs unprovided with excretory ducts do form some product which is reabsorbed into the blood is proved by the disastrous effects following their removal. The development of myxœdema in persons whose bronchocelic thyroids have been removed is a phenomenon familiar to all practitioners of medicine. It is further proved by the experiments of Hédou of Montpellier already communicated by me to THE LANCET that the continued vitality of a grafted portion of the pancreas ensures the animal against diabetes, even though the intra-abdominal portion be excised. That condition is, on the contrary, induced by the total ablation

of the normal but evicted pancreas, and also by the destruction of the grafts, the intra-abdominal portion being left *in situ*. As regards myxœdema, Professor Bouchard reports (Association Française pour l'Avancement des Sciences [Congress at Pau], September 19th, 1892), two cases recently treated by him at the Charité Hospital by means of injections of thyroid juice. Both patients were females, and the improvement was, in each instance, extraordinarily rapid. This statement is confirmed by Dr. Roger, who tells me that the effects of the application of the method were astonishing. The œdematous turgescence of the face, eyelids, lips, hands and forearms vanished rapidly, and this had the effect of appreciably diminishing the body weight. The improvement in the functional symptoms—slowness of speech, intellectual torpor, difficulty of locomotion—was no less striking. In both the subjects the temperature, which was subnormal, rose after the injections, and each dose of the thyroid extract was productive of such a sensation of warmth that they could abandon the habit they had contracted of remaining all day in bed fully dressed. Another notable result of the injections was diuresis, which was synchronous with the subsidence of the œdema. It is, however, only right to mention that these favourable results were not procured without some degree of discomfort being experienced by the sufferers. The local reaction was trifling, but headache and pains in the chest and limbs compelled M. Charrin (M. Bouchard's collaborator) to suspend the treatment more than once, and resume it after an interval of five or six days. As to the prognosis, MM. Bouchard and Charrin incline to the belief that the improvement, striking though it be, will prove to be only temporary, and they profess their inability to regard the method as a curative one. "Qui vivra verra."

#### *The Importance of Attitude in the Auscultation of Children.*

Another instructive communication made at the Pau Congress was one by Dr. Azoulay of Paris on the above-mentioned subject. The difficulty often experienced in analysing and localising abnormal heart sounds in the very young is known to most of us. The reason is that in the child the following elements come into play—viz., great rapidity of heart beats, the complicated character of the bruits and their vagueness. In such cases the puzzled practitioner contents himself with the hypothetical diagnosis of peri- and endo-carditis. Dr. Azoulay states that he has devised a means of rendering the problem much easier of solution. Dr. Jules Simon and himself have applied the method at the Paris Children's Hospital, and have thus been enabled to localise the extra- and intra-cardiac abnormal sounds. Dr. Azoulay places his little patients in the following attitude: trunk horizontal, dorsal position, arms raised vertically, lower limbs completely flexed, head raised. In this position of the body the normal sounds are considerably reinforced while the beats are slowed; consequently the abnormal sounds are intensified and better localised. The assumption by the patient of the above position notably increases the pericardial friction sound. The utility of variations of attitude is great in examinations for life insurance and in the examination of recruits. If a person supposed to be in good health experiences, when lying down, dyspœna and arrhythmia, and if the heart beats are not slowed—all of which symptoms are absent in the upright attitude—a lesion of the myocardium may be diagnosed and a fatal issue from asystole at a date more or less remote, according to the intensity of the above symptoms expected.

#### *A Method of Sterilising Water.*

Some weeks ago I supplied the readers of THE LANCET with the details of a method of sterilisation by filtration advocated by MM. Babès of Budapest. Dr. Burlureaux, Professor Agrégé at the Val-de-Grâce Military School, has devised yet another sterilising proceeding which has the merit of simplicity. Bacteriological researches have established the fact that, in depriving water of its lime salts, it is at the same time rendered free from microbes. Clarke's process (addition of quicklime) is relied on to rid the water of its calcium carbonate, and sodium carbonate is employed in the case of specimens containing calcium sulphate. In practice Dr. Burlureaux recommends the use of a powder which is composed of lime, sodium carbonate, alum and ferrous sulphate in varying proportions, according to the degree and kind of hardness of the water. For the dreaded Seine water the powder recommended is thus composed: Quicklime, 9 parts; carbonate of sodium, 5; powdered alum, 1; powdered iron sulphate, 1. As a rule, from thirty to fifty centigrammes would sterilise a litre of

water. The powder is added overnight and the water decanted in the morning for consumption. A knowledge of this simple means of sterilisation—based as it is on scientific data—will perhaps be found useful in these times of cholera. Paris, Sept. 27th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

#### *The Human Epidemic Bill.*

THE conference on the new Human Epidemic Bill for the whole empire began in the Imperial Office of Health yesterday, and is expected to last several days. Dr. Koehler, Director of the Office of Health, presides, and Drs. Koch, Pistar, Gerhardt, Schweningner, Kerschensteiner and Pettenkofer are among the members.

#### *How to Get First-rate Drinking-water.*

Dr. Hans Brackebusch, whose proposal for the disinfecting of water on a large scale I have already alluded to, answers inquiries as to the best method of disinfecting water for household use as follows: "Fill a stone vessel capable of holding about twenty litres to within a hand's breadth from the top with water, add three heaped tablespoonfuls of cement, and stir the mixture with a large wooden spoon for five minutes. The water then clears very quickly, and is fit for washing the body and for cooking everything except pulse. To get drinking-water, filter through coffee-paper into a carafe and add seltzer till the turbidness resulting at first disappears. The cement contains so much free lime that the killing of the bacilli is certain. The dissolved lime is converted by the carbonic acid of the seltzer into bicarbonate of lime, the substance to which mountain water owes its freshness. The cement must be fresh, and must not have lain beside smelling substances. Five pfennigs' (a little more than a halfpenny) worth of seltzer suffices for five litres of water."

#### *Professor Ernst Beckmann.*

Professor Ernst Beckmann of Giessen has been called to Erlangen. He established himself first as a private lecturer, and was then appointed Extraordinary Professor at Leipsic, where he was also Professor Ostwald's first assistant in the Chemical Institute. He was called to Giessen only last year, and taught chemistry there. His writings have appeared for the most part in the *Journal of Practical Chemistry*, the *Periodical of Analytical Chemistry* and the Reports of the German Chemical Society.

#### *Ancient Hygiene.*

The 156th number of the Collection of Popular Scientific Lectures, edited by Professors Virchow and Wattenbach, contains an essay on Ancient Hygiene by Professor Hagen of Bern, an important part of which is a survey of the opinions of the Roman military engineer Vitruvius on architectural hygiene.

#### *German Death-rates.*

The death-rates of the German cities in the week which ended on the 3rd inst. were as follows:—Elberfeld 17.8, Nuremberg 18.9, Barmen 20.3, Bremen 20.7, Stuttgart 22.6, Berlin 24.7, Dresden 25, Dantzic 26, Frankfort-on-the-Main 26.8, Munich 27.6, Königsberg 29, Strasburg 29, Düsseldorf 29.4, Aix-la-Chapelle 31.4, Halle 32.4, Cologne 33.7, Krefeld 34, Stettin 35.1, Breslau 36.2, Leipzig 36.4, Brunswick 36.8, Magdeburg 37.6, Hanover 38.9, Chemnitz 44, Altona 49.7, Hamburg and its suburbs 355.6.

#### *Miscellaneous Items.*

The German Government and the Society of German Women have established a hospital at Cameroons.

Army-Surgeon Dr. Kohlstock, who served for a year as medical officer in the German force in East Africa, has been appointed to the newly-founded chair of Tropical Hygiene in the Berlin Seminary for Oriental Languages.

Dr. Eduard Schubert, of Frankfort-on-the-Main, known as an investigator of the life and writings of Paracelsus and as a writer on that subject, died a few weeks ago.

Berlin, Sept. 27th.

ISLINGTON INFIRMARY.—On September 22nd the guardians met again to decide upon the site of the proposed new infirmary. After some discussion, the Board resolved that a deputation should wait upon the trustees of the Highgate Hospital, with a view to purchasing it.

## Obituary.

GEORGE DIXON LONGSTAFF, M.D. EDIN., L.F.P.S. GLAS.

GEORGE DIXON LONGSTAFF, who died at his residence, Butterknowle, Wandsworth, on Friday, Sept. 23rd, in his ninety-fourth year, was born on March 31st, 1799, at Bishop Wearmouth, in the county of Durham. At Edinburgh, in 1828, he obtained the degree of M.D., in which university he was for some time assistant to Dr. Hope, Professor of Chemistry, and in that capacity is believed to have been the first teacher of practical chemistry to medical students in this country. For some years he practised as a physician at Hull, and was one of the first lecturers at the Hull and East Riding School of Medicine, the formation of which institution, indeed, was largely owing to his exertions. In 1838 he married Maria, eldest daughter of the late Henry Blundell, J.P., of Hull, by whom he leaves two sons. After some years' residence in America he busied himself with mercantile affairs, and for many years acted as chairman of the firm of Blundell, Spence and Company, Limited, remaining a director of that company till his death. He was an active supporter of Canon Wilberforce's anti-slavery movement; and during the Chartist agitation of 1848, though he sympathised with many of the objects of the Chartists, he nevertheless acted as a superintendent of special constables and induced many Chartists to take the side of law and order. Dr. Longstaff was a frequent lecturer at Mechanics' Institutes, an educational movement which he spared no pains to promote. His interest in the spread of education was, moreover, displayed by the presentation, in 1887, of a reading room to the Wandsworth Free Library, founded under the auspices of the Free Public Library Commission, of which he was chairman. He was a founder and Vice-President of the Chemical Society of London, and for many years acted as chairman of the Royal Maternity Charity. He was one of the first members of the Wandsworth District Board of Works, and resided in that parish for upwards of fifty years.

JOHN CHURCHILL, M.R.C.S., L.S.A. LOND.

THE deceased gentleman whose remains have been deposited in the family vault at Egmont after cremation at Woking died on Friday, Sept. 2nd, at his residence, Hall Croft, Gosforth, Carnforth, Cumberland. He was born on the 4th of September, 1815, at Chertsey, in the county of Surrey. After serving an apprenticeship to a surgeon in that town he entered at Middlesex Hospital; subsequently obtaining the diploma of the Royal College of Surgeons. He was elected house surgeon to the Whitehaven Infirmary in 1843, but left this institution three years afterwards and went to London, leaving the metropolis after a stay of only one year for a vacancy which occurred at Gosforth. In 1880 he was placed on the Commission of the Peace for the county. In local affairs he took a very great interest, and the legacies which he left under his will to the following institutions show in a marked degree the spirit of benevolence which characterised the deceased gentleman. He has left legacies to the Whitehaven and West Cumberland Infirmary, of which institution he was a life governor; to the Middlesex Hospital, London; Gosforth Church building and augmentation funds; Seascale Church building fund; Discharged Prisoners' Aid Society, Carlisle; Industrial School at Cockermouth; and the Soup Kitchen, Whitehaven.

**CORONER FOR THE WESTERN DISTRICT.**—The Public Control Committee of the London County Council have recommended that Dr. C. Luxmoore Drew should be appointed Dr. Diplock's successor as coroner to the Western District. A number of members protested against the action of the committee in failing to submit several names for the consideration of the Council, and an amendment was proposed to the effect that the report should be referred back to the committee, in order that three names might be submitted to the Council. It was finally decided to vote upon eight selected candidates who had appeared before and been examined by the committee, the result being that Dr. Drew was elected by a large majority.

## Medical News.

**UNIVERSITY OF DURHAM.**—The following candidates at the Second Examination for the degree of Bachelor in Medicine at the College of Medicine, Newcastle-on-Tyne, have satisfied the Examiners:—

*Second Class Honours.*—Lionel Claude Everard Calthrop, M.R.C.S., L.R.C.P., London Hospital.

*Pass list.*—Wilfred Ernest Alderson, Robinson Brown, Wm. Andrew P'Anson Charlton, Percival Davidson, Gilbert Gocher, William Thomas Harkness, Christopher Julius Jeaffreson, Tom Sanderson, George William Scott, William Smith, and Percy Hugh Wardell-Johnson, College of Medicine, Newcastle-on-Tyne; Leonard Harman, St. Thomas's Hospital; Alfred Grosvenor Hinks, M.R.C.S., L.R.C.P., and Edwd. John Steegmann, M.R.C.S., M.R.C.P., L.S.A., St. Mary's Hospital; William Ernest Jones, M.R.C.S., L.R.C.P., and Bertie James Mayne, Middlesex Hospital; Frank Laughton-Smith, Ernest Percy Satchell, and George Hedley Tomlinson, Mason College, Birmingham; Walter Frederic Miller and Fredk. William Rowland, Guy's Hospital; John Ralph Prior, King's College Hospital; Ferdinand Clarence Smith, M.R.C.S., M.R.C.P., L.S.A., University College, London.

**SOCIETY OF APOTHECARIES OF LONDON.**—The following candidates have passed in the respective subjects:—

*Surgery.*—J. N. Dobie, Cambridge and St. Mary's Hospital; G. Grace, Bristol; G. B. Hillman, Yorkshire College, Leeds; S. L. Martin, London Hospital; G. H. Jones, Middlesex Hospital; R. A. Smith, Edinburgh.

*Medicine, Forensic Medicine and Midwifery.*—E. Henry, St. Bartholomew's Hospital; M. Richards, London Hospital; J. M. Swanson, Charing-cross Hospital; P. M. Thomas, Cleveland, U.S.A.; A. E. Wilson, St. Mary's Hospital.

*Medicine and Forensic Medicine.*—W. Fowler, Durham; G. L. Godwin, Edinburgh.

*Medicine and Midwifery.*—W. E. Barker, Owens College, Manchester; F. B. Lewis, London Hospital; E. D. Madge, Middlesex Hospital; J. H. Roberts, Guy's Hospital.

*Medicine.*—D. Berns, Royal Free Hospital.

*Forensic Medicine and Midwifery.*—F. V. Denne, Westminster Hospital; E. J. T. Jones, St. Thomas's Hospital; A. J. Russell, London Hospital.

*Forensic Medicine.*—B. S. Foulds, Charing-cross Hospital; S. L. Martin, London Hospital; T. E. Pallett, Westminster Hospital.

*Midwifery.*—E. C. Adams, St. Bartholomew's Hospital.

To Messrs. Dobie, Fowler, Grace, Hillman, Lewis, Martin, Pallett, Smith, Thomas and Wilson was granted the diploma of the Society entitling them to practise Medicine, Surgery and Midwifery.

**LITERARY INTELLIGENCE.**—Dr. von Schroeder has retired from the joint editorship of the *St. Petersburger Medicinische Wochenschrift*, his place being taken by Dr. Rudolf Wanach of St. Petersburg.—A new medical journal has appeared in New York under the editorship of Dr. Aulde. It is entitled *The American Therapeutist*, and is to be devoted exclusively to therapeutics.

**A PAPER on the Urgent Need for amended Legislation for Inebriates** will be read by Mr. W. H. Williams, M.R.C.P., at the quarterly general meeting of the Society for the Study and Cure of Inebriety, at 11, Chandos-street, W., on Thursday afternoon, Oct. 4th, at 4 o'clock, when the chair will be taken by the President, Dr. Norman Kerr, F.L.S.

**FIRE AT THE JESSOP HOSPITAL, LEAVYGREAVE.**—A fire, which was fortunately discovered before very serious consequences resulted, broke out on the 22nd ult. at the above hospital. The disaster was probably due to the ignition of the floor of one of the rooms which it was desired to fumigate by means of a pan of sulphur.

**WATER-SUPPLY OF HASTINGS.**—The Hastings Borough Corporation are engaged in carrying out experiments at Brede, with a view of getting an additional water-supply to the town. When the wells are sunk there will be a daily yield of 3,000,000 gallons. The cost of the undertaking is roughly estimated at £70,000. The water from the springs is reported to be exceptionally pure.

**PROPOSED ISOLATION HOSPITAL, BANSTEAD DOWNS.**—Last week a meeting of the Joint Committees of the Sutton and Carshalton Local Boards and the Epsom Rural Sanitary Authority was held to consider the suggested site on Banstead Downs for the erection of an isolation hospital. It was resolved that the proposed site, on the terms offered, be accepted. It was also resolved that application be made to the Central Board for power to constitute the three local authorities into a joint board for the management of the hospital.

**EXETER CENTRE ST. JOHN AMBULANCE ASSOCIATION, GREAT WESTERN RAILWAY BRANCH.**—On Sept. 26th the Duke of Edinburgh presented the students who had been successful in the Great Western Railway Branch of the Exeter Centre of the St. John Ambulance Association examination with certificates.

**THE NEW WESTERN HOSPITAL.**—At a meeting of the London County Council on Sept. 26th it was agreed, on the recommendation of the Finance Committee, to lend to the Metropolitan Asylums Board the sum of £46,825 for the purpose of erecting additional buildings at the Western Hospital and for the reconstruction of the Western Ambulance Station.

**NEW DISINFECTING CHAMBER FOR ISLINGTON.**—On the initiative of Mr. Alfred Harris, medical officer of health, it has been decided by the public health committee to recommend to the vestry the desirability of erecting a disinfecting chamber on a piece of ground within the bounds of the parish. The estimated cost of building and apparatus is £1500.

**FOOTBALL CASUALTIES.**—Whilst playing a game on the 17th ult. at Dixon's-green, Dudley, a youth badly fractured his left arm. On Saturday, during a match between Laurieston and King's-park, Falkirk, the King's-park goalkeeper, through colliding in the midst of a scrimmage with one of the opposing forwards, fractured his left leg just above the ankle.

**DISINFECTION OF PARCELS.**—An arrangement has been come to between the General Post Office authorities and the Clerkenwell Vestry whereby the latter undertake the disinfection of Post Office parcels at a charge of six shillings each time the apparatus is used, irrespective of the number of parcels, and this charge to include the services of two men fetching the parcels in the disinfecting truck and returning them when disinfected.

The number of patients remaining in the several fever hospitals of the Metropolitan Asylums Board at midnight in Sept. 27th was as follows:—Eastern Hospital, 415 scarlet fever, 64 diphtheria and 37 enteric fever; North-Western Hospital, 411 scarlet fever, 98 diphtheria and 21 enteric fever; Western Hospital, 302 scarlet fever, 45 diphtheria, 3 typhus fever and 12 enteric fever; South-Western, 307 scarlet fever, 61 diphtheria and 25 enteric fever; South-Eastern, 404 scarlet fever, 20 diphtheria and 9 enteric fever; Northern Hospital, 824 scarlet fever and 18 diphtheria; and at the Gore Farm Hospital there were 724 cases of scarlet fever. The hospital ship *Atlas* had 2 cases of small-pox.

**PRESENTATIONS.**—Mr. A. W. Douglas, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of Brushgrove, Clarence River, New South Wales, was presented on July 5th last, on the occasion of his leaving the district, with an illuminated address and a gold Waltham watch, suitably inscribed.—Dr. Arthur W. Kempe, of Exeter, has been presented by the Exeter Fire Brigade with a silver salver, in appreciation of his services as their medical officer.—Mr. A. E. Wynne, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of Dublin, has been the recipient of a handsome illuminated address and a purse of sovereigns, from the medical and surgical staff of the Mercer's Hospital in that city, as a token of respect and esteem.

## LIST OF PRIZES AT THE LONDON MEDICAL SCHOOLS.

The following is a list of the prizes &c. awarded for the sessions 1891-92.

**ST. BARTHOLOMEW'S HOSPITAL.**—Lawrence Scholarship and Gold Medal: E. W. G. Masterman. Brackenbury Medical Scholarship: E. H. E. Stack. Brackenbury Surgical Scholarship: A. H. Buck and A. N. Weir, equal. Senior Scholarship in Anatomy, Physiology and Chemistry: E. J. Toye; *prox. acc.* F. Fraser. Open Scholarships in Science, Chemistry and Physics: M. Coleman and T. Horder, equal. Biology and Physiology: H. T. Gillett. Junior: V. H. Blackman. Preliminary Scientific Exhibition: J. Hussey. Jeaffreson Exhibition: F. H. Nimmo. Kirkes Scholarship and Gold Medal: H. L. Brooksbank. Bentley Prize (Surgical): H. J. Paterson. Hichens Prize: H. J. Paterson. Wix Prize: No award. Harvey Prize: M. G. Pearson; 2, J. Currie; 3, G. A. C. Calvert; 4, G. H. Sowry; 5, A. W. R. Cochrane; 6, E. J. Toye; 7, F. A. Smith; 8, S. P. Kesteven. Sir George Burrows' Prize. Skynner Prize: A. B. Blackwell and W. B. Jones, equal. Practical Anatomy (Junior)—Treasurer's Prize: S. P. Huggins; 2, G. E. Dodson; 3, S. P. W. Bristocke and W. R. Stowe; 5, J. P. Maxwell; 6, E. J.

Simmonds; 7, W. K. Miller; 8, L. F. Marks; 9, F. H. Nunn. Practical Anatomy (Senior)—Foster Prize: J. H. Meacher; 2, T. P. Legg; 3, H. T. Gillett and A. Woodward; 5, G. H. Sowry; 6, J. Currie; 7, G. A. C. Calvert; 8, M. G. Pearson; 9, A. W. R. Cochrane. Shuter Scholarship: W. M. Borchers. Junior Scholarships: J. T. Horder; 2, J. Hussey. Junior Scholarship in Chemistry (1891): E. J. Toye; 2, J. Currie and E. G. B. Drury.

**ST. GEORGE'S HOSPITAL.**—£125 entrance scholarship: H. M. Cooper. £50 entrance scholarship: J. M. Manning. £65 entrance scholarships: F. C. Bottomley, C. Kempson. Pollock Prize in Physiology: C. R. Watson. The Henry Charles Johnson Prize in Anatomy: Reginald Norman. The William Brown £100 Exhibition: R. G. Turner. The William Brown £40 Exhibition: C. C. S. Barry. Sir Charles Clarke's: A. E. Weston. The Treasurer's: G. H. Gouldemith. The Thompson Medal: G. Carré. The Brackenbury Prize in Surgery: A. L. Tatham. Third Year's proficiency: G. R. Baldwin. Second Year's proficiency: L. G. Davies. First year's proficiency: C. R. Keyser.

**GUY'S HOSPITAL.**—The Treasurer's Gold Medal for Clinical Medicine: Arthur Mantell Daldy, Romford; Alfred Theodore Rake, Fordingbridge, *proxime accessit*. The Treasurer's Gold Medal for Clinical Surgery: Alfred Theodore Rake, Fordingbridge. Gurney Hoare Prize for Clinical Study? Herbert Edward Durlum, London. Boney Prize for Pathology: Arthur Mantell Daldy, Romford. Golding-Bird Prize and Gold Medal for Diagnosis: Charles Satchell Pantin, Blackheath. Sands Cox Scholarship for Physiology: Charles John Harnett, Guildford; Alfred Sater, Blackheath, *proxime accessit*. Michael Harris Prize for Anatomy: Henry Alfred Moffat, Grahamestown, Cape Colony. The Arthur Durham Prizes for Dissection: First Year's Students—Norman Howard Pike, Streatham-common, prize, £5; Richard Hamilton Ashwin, Spalding, certificate: Arthur George Butler, Beckenham, Kent, certificate. Second Year's Students—Richard Foster Clark, Plymouth, prize, £15; James Henry Horton, Charlton, certificate; Henry Alfred Moffat, Grahamestown, Cape Colony, certificate. Prizes for Fourth Year's Students: Francis Jordan Coleman, Hunmanby, Yorks; Charles Satchell Pantin, Blackheath, and George Frederic Still, Tooting-park, equal, £12 each; Arthur John Sharp, Bromley, Kent, certificate; William John Johnson, Shefford, certificate; David Morgan Beddoe, Merthyr Tydfil, certificate. Prizes for Third Year's Students: John Alexander Howard, Canonbury, first prize, £25; Hugh Milton Stewart, Beckenham, Kent, second prize, £10. Prizes for Second Year's Students, 1891: Guy Eugene Manning, Hammersmith, first prize, £25; Leopold Ernest Valentine Every Clayton, Nelson, Lancashire, second prize, £10; John Alexander Howard, Canonbury, certificate; Arthur Henry Leote, Wellingborough, certificate. Prizes for First Year's Students, 1891: Francis James Steward, Old Charlton, first prize, £50; Charles John Harnett, Guildford, and Alfred Salter, Blackheath, equal, £12 10s. each; Harold Nolan, London, certificate. Prizes for First Year's Dental Students: John Brodribb Parfitt, Reading, prize, £10; Charles Henry Oram, South Molton, certificate; George Sidney Frederick Manton, London, certificate. Prizes for Second Year's Dental Students: Richard Ernest Woodcock, Pontefract, Yorks, prize, £15; Samuel Ralph Athporhe, Bromley, Kent, certificate; Archibald Rutledge Henry, Hastings, certificate. Prizes for Practical Dentistry: Stephen Keele, London, prize, £10; Archibald Rutledge Henry, Hastings, certificate; Harold Arthur Turner, Eastbourne, certificate. Open Scholarships in Arts: Gerald Burton-Brown, Cambridge, 100 guineas; Norman Lavers, Tasmania, 50 guineas. Open Scholarships in Science: Arthur George Butler, Beckenham, Kent, Peter Henry Haylett, Kimberley, Cape Colony, and Hugh Milton Stewart, Beckenham, Kent, equal, £61 5s. each.

**LONDON HOSPITAL.**—Entrance Science Scholarships, instituted 1875, given for proficiency in the subjects required for the preliminary scientific M.B. examination at the University of London: £75 scholarship, H. Innes; £50 scholarship, C. E. Davenport. Buxton Scholarships, given for proficiency in the subjects required for the preliminary examinations: £30 scholarship, G. H. Warren; £20 scholarship, J. G. Wallis. Clinical Medicine: £20 scholarship, given jointly by the House Committee and the Medical Council, A. Strange; honorary certificate, F. J. Woollacott. Clinical Surgery: £20 scholarship, given jointly by the House Committee and the Medical Council, A. Strange; honorary certificates, J. W. Hull and J. E. Gilbert Rogers. Clinical Obstetrics: £20 scholarship, given jointly by the House Committee and the Medical Council, A. Strange; honorary certificates, J. W. W. Stanton and H. L. Barnard. Duckworth Nelson Prize (biennial): Awarded last year. Lethaby Prize: £30 prize for proficiency in chemistry, J. C. Spillane and D. P. Harris; honorary certificate, R. Bebb. Hutchinson Prize (triennial): Awarded 1890, W. G. Noble. Anatomy, Physiology and Chemistry: £25 scholarship, given by the Medical Council, W. B. Butler. Anatomy and Physiology: £20 scholarship, given by the Medical Council, Elgar Down; honorary certificate, H. Innes. Dressers' Prizes, for Zeal, Efficiency, and Knowledge of Minor Surgery, given by the House Committee: £15 prizes, J. D. Galloway and A. Gooding. Practical Anatomy Prizes: £6 prize, H. E. B. Porter; £4 prize, M. Cameron; £3 prize, J. V. Worthington; £3 prize, J. C. Spillane; £3 prize, A. E. Lovitt; £2 prize, A. Gooding; £2 prize, H. M. Rigby.

**LONDON SCHOOL OF MEDICINE FOR WOMEN.**—Summer Session, 1891.—Materia Medica: Examiner, Dr. Sainsbury—Prize, Miss Moffett; certificates, Miss S. Hughes and Miss Despard. Practical Chemistry: Examiner, C. W. Heaton, F.C.S.—Prize, Miss Yardley; certificates, Miss Thornett and Miss Hull. Practical Organic Chemistry: Examiner, C. W. Heaton, F.C.S.—Prize, Miss E. Knight; certificates, Miss Bennett, Miss de Steiger, Miss Appel, and Miss Flint. Histology and Practical Physiology: Examiner, Professor Halliburton—Prize, Miss M. Benson; certificates, Miss Appel, Miss M. Webb, Miss Turle Evans and Miss Dodson. Forensic Medicine: Examiners, Dr. Dupré and Mrs. Dowson, L.R.C.P. and S.I.—Prize, Miss Hatch; certificates, Mrs. Rye, Miss Murdoch and Miss Bale. Winter Session, 1891-92.—Physiology: Examiner, Professor Halliburton, F.R.C.S.—Prize, Miss Hayward; certificates, Miss Appel, Miss Stoney, Miss Thornett, Miss Patch, Miss Lewin, Miss Flint and Miss Vaughan. Chemistry: Examiner, C. W. Heaton, F.C.S.—Prize, Miss Yardley; certificates, Miss Colebrook and Miss Rawlinson. Organic Chemistry: Examiner, C. W. Heaton, F.C.S.—Prize, Miss Sweetman; certificates, Miss Stoney and Miss Caine. Anatomy, first year: Examiner, Stanley Boyd, F.R.C.S.—Prize, Miss Rawlinson; certificates, Miss Stoney, Miss Colebrook, Miss Hull, Miss Long, Miss Thorne, Miss Despard, Miss Sutherland, Miss Vaughan and Miss Adams. Anatomy, second year: Examiner, Stanley Boyd, F.R.C.S.—Prize, Miss Hodgins; certificates,

Miss Lency, Miss Appel, Miss Holt and Miss de Steiger. Medicine: Examiners, Mrs. Garrett Anderson, M.D., and Dr. H. Donkin.—Prize, Mrs. Rye; certificates, Miss Moffatt, Miss Bale and Miss Murdoch. Midwifery: Examiner, Dr. Ford Anderson.—Prize, Miss Hatch; certificates, Mrs. Rye, Miss Boyle, Miss Bale, and Miss Murdoch. Gynecology: Examiner, Mrs. Scharlieb, M.D.—Prize, Miss Murdoch; certificates, Miss Jones, Miss Bale, Miss Boyle, Miss Moffatt, Miss E. Knight, Miss Gray, Mrs. Rye, Miss Westlake, Miss Harding, Miss Nicholas, Miss Corthorn, Miss Pellatt, Miss Berne, Miss Helen Greene, Miss Armitage, Miss Hatch and Miss Mitcheson. Operative Midwifery: Examiner, Mrs. Stanley Boyd, M.D.—Prize of five guineas given by Mr. Wood. Miss Hatch; certificates, Mrs. Rye and Miss Berne. No certificate is given under 60 per cent. of marks. Entrance scholarship for October, 1891, given by the executive council, value £30, awarded to Miss Latham; examiner, G. S. Carr, M.A. Fanny Butler scholarship, value £20 a year for four years, Miss Von Hippo; Helen Prideaux prize, £50, Miss M. Sturge, M.B. Lond.

ST. MARY'S HOSPITAL.—Entrance scholarship in Natural Science of 100 guineas, 1891, F. A. St. John; entrance scholarships in Natural Science of 60 guineas, B. Lewitt, H. Sugden and W. B. Stevenson; University scholarships of 60 guineas, W. J. Harris and J. A. Wright; Epsom scholarship of value of £120, no award. Summer Session, 1891.—Second year.—Midwifery: A. E. Wilson, prize; A. Stanley and G. Riddick, certificates of honour. Medical Jurisprudence: J. E. Beggs, B.A., and A. E. Wilson, prizes; W. W. Linington and R. Corle, certificates of honour. First Year.—Materia Medica: J. E. P. Davies, prize; W. Ashdowne, A. W. Sanders and J. C. Smellie, certificates of honour. Botany: B. Lewitt and F. A. St. John, prizes; C. D. Lindsey and W. B. Stevenson, certificates of honour. Practical Chemistry: W. Ashdowne, prize; J. N. MacDonald, H. G. Jones and F. Keogh, certificates of honour. Chemistry: E. Hanson, prize; C. S. Murray and W. Ashdowne, certificates of honour. Winter Session, 1891-92.—Third year.—Medicine: C. T. Parsons, prize; C. M. Rhodes, W. Broadbent, B.A., and J. L. Morton, certificates of honour. Surgery: J. L. Morton, prize; C. T. Parsons and C. M. Rhodes, certificates of honour. Practical Surgery: J. L. Morton, prize; J. E. Beggs, B.A., certificate of honour. Pathology: J. E. Beggs, B.A., prize; C. T. Parsons and A. F. Bill, certificates of honour. Third and Fourth Years.—Prizes in Ophthalmology of £10 10s.: E. L. P. Payne and C. M. Rhodes. Prize in Dermatology of £5 5s.: J. E. Beggs, B.A. Clinical Surgery: J. E. Beggs, B.A., prize (1891-92). Clinical Medicine: E. A. Nathan, prize (1891-92). Second Year.—Anatomy: A. W. Sanders, prize; J. E. P. Davies, E. Hanson and J. C. Smellie, certificates of honour. Physiology: A. W. Sanders, prize; J. E. P. Davies and R. W. Dodgson, certificates of honour. First Year.—Anatomy: W. Ashdowne and M. F. Squire, prizes; W. B. Stevenson and W. D. Wiggins, certificates of honour. Physiology: F. A. St. John, prize; P. S. Lelan and W. Ashdowne, certificates of honour. Special Prizes, 1891.—Students of First Year—for general proficiency in Anatomy, Physiology, Materia Medica and Chemistry: A. W. Sanders. Students of Second Year—for general proficiency in Anatomy, Physiology, Midwifery and Medical Jurisprudence: A. E. Wilson. Students of Third Year—for general proficiency in Medicine, Surgery, Pathology and Operative Surgery, no competitors. Prosectors: A. W. Sanders and J. C. Smellie.

MIDDLESEX HOSPITAL.—Broderip Scholarships, for the best Examination at the Bedside and in the Post-mortem Room: First, W. F. Lucas; second, H. B. Long. Governors' Prize: A. Baldwin. Exhibition in Anatomy: First year, C. W. Alford. Medicine: F. E. Rock. Surgery: H. C. Thomson. Practical Medicine and Therapeutics: H. C. Thomson. Practical Surgery: W. F. Lucas. Practical Midwifery: B. W. Nankivell. Anatomy: A. P. Coker. Physiology: E. J. Dobbin. Chemistry: R. H. S. Preston. Hotley Prize: A. Baldwin. Lyell Medal: W. F. Lucas. Dissections: E. J. Dobbin. Pathological Anatomy: R. A. Young. Midwifery: W. T. Pugh and M. W. W. Curtis, equal. Forensic Medicine: C. H. Watson. Materia Medica: A. E. Walter. Practical Chemistry: T. T. Day. Practical Physiology: N. B. Harman. Entrance Scholarships: First, E. du P. Aubin; second, Charles Roberts. Certificates of Honour, in order of merit: Medicine—W. P. Lucas, A. Baldwin, H. C. Thomson. Practical Surgery—T. W. Lockett, A. Baldwin, F. E. Rock, C. H. Watson. Anatomy—E. J. Dobbin, M. B. Pinchard, N. E. Thomas, C. H. J. Robinson. Physiology—T. H. Wells, A. P. Coker, M. A. Raper. Practical Medicine—A. E. Shepherd and A. Baldwin, equal. F. E. Rock. Surgery—A. Baldwin, F. E. Rock. Pathological Anatomy—F. E. Rock, W. M. C. Wanklyn, W. T. Pugh, A. P. Coker, A. Cortes. Midwifery—F. E. Rock, G. A. Jones, R. A. Young. Practical Midwifery—T. Carwardine, A. E. Shepherd, N. J. Smith, T. A. Beddy. Forensic Medicine—H. C. Thomson, A. Baldwin, F. E. Rock. Materia Medica—C. W. Alford, B. J. Mayne, N. B. Harman. Practical Chemistry—T. Thomas, W. H. Wykes, D. J. Jones; E. W. Hopkins, T. H. Jones and J. W. Myler, equal; C. C. Smith and E. Z. Ward, equal. Practical Physiology—F. Dodd, E. K. Herring. Chemistry—C. Roberts.

ST. THOMAS'S HOSPITAL.—Entrance Science Scholarships: A. H. Stewart, Regent's Park, scholarship, 125 guineas, and certificate of honour; F. H. Gervis, Haverstock-hill, scholarship, £60, and certificate of honour. First Year's Students: J. C. Harcourt, South Woodford, the William Tite Scholarship, £27 10s., and certificate of honour; B. Dyball, Brixton, college prize, £20, and certificate of honour; A. H. Stewart, Regent's Park, college prize, £10, and certificate of honour; F. B. Thornton, Leicester; M. Takayasu, Japan; A. J. Martineau, Lupus street; F. H. Gervis, Haverstock-hill; H. N. A. Gode, Kensington.—Certificates of honour. Second Year's Students: G. G. Gunge, Croydon, the Peacock Scholarship, £38 10s., and certificate of honour; W. E. F. Timley, Whitby, college prize, £20, and certificate of honour; E. L. Perry, St. George's-square, college prize, £10, and certificate of honour; A. L. Home, Hampstead; W. H. J. Paterson, Shepherd's-bush, and E. O. Thurston, Pantom-street, equal; W. D. Frazier, Penarth—certificates of honour. Third Year's Students: A. E. Russell, Greenwich, college prize, £20, and certificate of honour; S. W. R. Richardson, Whitby, second tenure of the Musgrove Scholarship, and certificate of honour. Practical Medicine: A. E. O. Milton, Brighton, the Mead Medal, founded by Mr. and Mrs. Newman Smith. Surgery and Surgical Anatomy: W. G. Sutcliffe, Clapham, the Cheselden Medal, founded by the late Mr. George Vaughan; E. Smith, Wandsworth Common; W. Redpath, Norwood-road, certificates of honour. Solly Medal and Prize: W. B. Winston, Oxford-gardens, medal and prize, £20. For General Proficiency and Good Conduct: E. Smith, Wandsworth Common, the Treasurer's Gold

Medal. Certificates of Honour: Anatomical Assistants—S. W. F. Richardson, A. E. Russell. Prosectors: H. C. Crouch, G. G. Gonge, A. L. Home, L. N. Pentreath, E. L. Perry, E. O. Thurston. Assistants in Physiological Laboratory: W. E. Dixon, H. M. Harrison, J. S. Hudson, W. H. J. Paterson. Pathological Assistants: J. C. Durston, E. M. Hainworth, W. G. Sutcliffe. House Physicians: C. R. Box, T. H. Kellock, C. Latter, J. J. Perkins, C. Wyman; non-resident, G. R. F. Stillwell, D. F. Shearer, W. P. Purvis. House Surgeons: L. Cobbett, T. H. Haydon, J. R. Harper, C. Wyman, T. H. Hollock, C. R. Box, W. F. E. Milton, T. A. M. Forde. Assistant House Surgeons: L. Cobbett, C. Wyman, W. F. E. Milton, T. A. M. Forde, T. H. Kellock, C. R. Box, H. Burden, P. J. Atkey. Obstetric House Physicians: Senior—J. R. Harper, W. G. G. Stokes, W. F. Umney, A. Banks; Junior—W. L. Wainwright, T. H. Haydon. Ophthalmic House Surgeons: C. H. Usher, S. G. Toller. Clinical Assistants in the Special Departments: Skin, F. W. Beville, L. G. Soudamoro; throat, P. J. Atkey, A. Dalzell, T. A. M. Forde; ear, E. H. G. Morris, J. H. Fisher, C. S. Wallace.

UNIVERSITY COLLEGE.—Winter Session.—Entrance Exhibitions: £100, W. B. L. Trotter of London; £80, C. B. Goring of London; £40 each, equal, J. C. H. Leicester of Dulwich and A. J. Rodocanachi of London. Atchison Scholarship (£30 per annum for two years): F. V. Bunch of London. Atkinson Morley Scholarship (£45 per annum for three years): Douglas Drew of London. Bruce Medal: F. B. Bunch of London. Physiology.—Senior Class: gold medal, J. H. Cook of London; silver medal, P. J. Edmunds of London; certificates, 3<sup>rd</sup>, equal, F. W. Chandler of Derby, A. Dimsey of London, T. C. H. Stevenson of Strabane; 6<sup>th</sup>, G. B. Hunt of London. Second Class: F. J. Coutts of London, F. G. Crookshank of London, S. E. Shoppee of London, C. C. Weeks of Gibraltar. Third Class: C. Banting of London, J. N. Brown of London, A. Hunnard of London, T. A. Starkey of Northwich, A. Young of Sheffield. Junior Class: silver medal, J. Shardlow of Clay Cross; certificates, 2<sup>nd</sup>, H. B. Shaw of Sydney; 3<sup>rd</sup>, D. N. Nabarro of London; 4<sup>th</sup>, J. C. H. Leicester of Dulwich; 5<sup>th</sup>, W. G. Savage of Blackheath; 6<sup>th</sup>, S. H. Belgrave of Putney; 7<sup>th</sup>, P. K. Byrne of Drogheda. Second Class: J. N. Bhadhurji of Bombay, J. A. Belcher of Gnosall, T. R. H. Bucknall of Kidderminster, F. B. Carter of Gravesend, C. C. Clark of Leicester, A. M. Connell of Barbados, C. B. Goring of London, L. S. Hughes of New Zealand, A. D. Ketchen of Middlebrough, J. H. Murray of Honour Oak, J. W. F. Rait of Forest-hill, A. J. Rodocanachi of London, T. O'N. Keel of London, J. D. Russell of Greenwich, E. Thomas of Cardigan, W. B. L. Trotter of London. Third Class: H. J. Price of New Malden, A. R. Todd of Jamaica. Pathology.—Practical Course: Tuke Silver Medal, J. L. Bunch of London; Tuke Bronze Medal, I. Costa of Jamaica; certificate, 3<sup>rd</sup>, F. T. Travers of London. Anatomy.—Senior Class: Gold medal, A. Dimsey of London; first silver, T. H. C. Stevenson of Strabane; second silver, G. B. Hunt of London. Second Class: F. J. Coutts of London, A. Hunnard of London, T. A. Starkey of Northwich. Third Class: C. Banting of London, J. C. Hibbert of Watford, A. W. Jenkins of Llandysul, W. R. Nettle of Callington, E. Stork of Ceylon, S. E. Shoppee of London. Junior Class: Silver medal, J. D. Russell of Greenwich; certificates, 2<sup>nd</sup>, C. C. Clark of Leicester; 3<sup>rd</sup>, J. A. Belcher of Gnosall; 4<sup>th</sup>, H. B. Shaw of Sydney; 5<sup>th</sup>, A. D. Ketchen of Middlebrough; 6<sup>th</sup>, H. J. Price of New Malden. Second Class: J. N. Bhadhurji of Bombay; C. B. Goring of London; D. N. Nabarro of London; A. J. Rodocanachi of London; E. Thomas of Cardigan. Third Class: P. K. Byrne of Drogheda, H. A. Günther of Hampton Wick, J. C. H. Leicester of Dulwich, J. W. F. Rait of Forest Hill. Medicine.—Gold medal, F. V. Bunch of London; first silver, M. Randall of Beaminster; second silver, J. Jones of Clydach; certificates, 4<sup>th</sup>, C. G. Spencer of New Zealand; 5<sup>th</sup>, A. D. Heath of Exeter; 6<sup>th</sup>, G. A. Stephens of Cardigan. Second Class: A. Y. Fullerton of Sydney; D. Keele of London. Surgery.—Gold medal, F. V. Bunch of London; first silver, M. Randall of Beaminster; second silver, C. G. Spencer of New Zealand; certificates, 4<sup>th</sup>, H. A. Ballance of London; 5<sup>th</sup>, E. W. Selby of Lewisham. Second Class: A. D. Heath of Exeter, G. A. Stephens of Cardigan. Third Class: A. Y. Fullerton of Sydney, W. W. Hodgins of London, D. Keele of London. Chemistry.—Prize, A. R. Tod of Jamaica; certificate, 2<sup>nd</sup>, L. S. Hughes of New Zealand. Practical Surgery.—Erichsen Prize, David Keele of London; certificates, 2<sup>nd</sup>, C. G. Spencer of New Zealand; 3<sup>rd</sup>, H. A. Ballance of London. Second Class: C. J. Harrison of Devonport, W. W. Hodgins of London, G. A. Stephens of Cardigan, F. W. Wesley of London, E. S. Worrall of Manchester. Clinical Medicine.—Senior Class: Fellowes Gold Medal, F. V. Bunch of London; Fellowes Silver Medal, F. W. Wesley of London; certificates, 3<sup>rd</sup>, H. A. Ballance of London; 4<sup>th</sup>, J. Jones of Clydach, 5<sup>th</sup>, W. T. Lister of Leytonstone; 6<sup>th</sup>, C. G. Spencer of New Zealand; 7<sup>th</sup>, M. Randall of Beaminster; 8<sup>th</sup>, C. J. Harrison of Devonport. Second Class: E. Evans of Dinas Mawddwy, A. D. Heath of Exeter, D. Keele of London, A. G. Liny of London, J. E. Ramsay of Sydney, G. A. Stephens of Cardigan, T. Streetfold of London. Third Class: A. Y. Fullerton of Sydney, J. L. Sawers of Blackheath. Junior Class: J. R. Bradford, M.D., D.Sc.; Fellowes Silver Medal, R. W. Lake of Sydney; certificates, 2<sup>nd</sup>, T. B. Stedman of Leighton Buzzard; 3<sup>rd</sup>, E. J. Smyth of New Barnet; 4<sup>th</sup>, J. L. Bunch of London. Second Class: M. Ashley of Modbury, P. Best of St. Ives, P. S. Eves of London, T. R. Llewellyn of Llantwitvadro. Third Class: W. Drake of Canterbury, E. F. Harwood of Lisbon, J. M. Stewart of London, A. M. Watts of Acton. Clinical Surgery.—Liston Gold Medal: A. B. Harris of Oxford. Clinical Dental Surgery.—Silver medal, H. A. Ballance of London; certificates, 2<sup>nd</sup>, F. V. Bunch of London, 3<sup>rd</sup>, G. A. Stephens of Cardigan and F. W. Wesley of London, equal; Second Class, H. R. S. Clarke of Malvern. Summer Session.—Histology and Practical Histology.—Gold medal, P. K. Byrne of Drogheda; silver, J. A. Belcher of Gnosall and C. B. Goring of London equal; certificates, 4<sup>th</sup>, J. D. Russell of Greenwich, 5<sup>th</sup>, J. C. H. Leicester of Dulwich, D. N. Nabarro of London and A. J. Rodocanachi of London equal, 8<sup>th</sup>, H. B. Shaw of Sydney. Second Class: H. Clifford of London. Third Class: H. R. Emms of London. Pathology.—Filliter Exhibition of £30: J. Le M. Bunch of London; silver medal, Isaac Costa of Jamaica. Chemistry (Chemistry and Chemical Physics).—Prize, R. H. Hyde of London; certificates, 2<sup>nd</sup>, L. S. Hughes of New Zealand and L. E. Cressy of Ealing. Second Class, H. Chatterton of London. Third Class: C. M. Atkinson of Ashford, P. D. Barker of Kimpton and C. G. Moffitt of Clapham. Practical Chemistry.—Prize, R. H. Hyde of London; certificates—2<sup>nd</sup>, L. S. Hughes of New Zealand; 3<sup>rd</sup>, C. G. Moffitt of Clapham; 4<sup>th</sup>, P. D. Barker of Kimpton; 5<sup>th</sup>, L. E. Cressy of Ealing, 6<sup>th</sup>, H. Chatterton of London and C. M. Atkinson of Ashford, equal. Third Class: H. H. Fawcett of London. Senior Practical Class: prize,

J. S. Bolton of Whitby; certificates, 2\*, A. Dimsey of London; 3\*, J. N. Brown of London. Second Class: F. J. Coutts of London. Organic Chemistry.—Prize J. S. Bolton of Whitby; certificate, 2\*, F. J. Coutts of London. Second Class: T. A. C. Stevenson of Strabane. Third Class: F. W. Chandler of Derby and A. Dimsey of London. Junior Organic Chemistry.—Certificate, 1\*, J. Shardlow of Clay Cross. Third Class: C. B. Goring of London. *Materia Medica* and Therapeutics.—Gold medal, A. Dimsey of London; silver medal, T. A. Starkey of Northwich; certificates, 3\*, J. S. Bolton of Whitby; 4\*, J. Pole Kitson of Southsea, and H. J. Price of New Malden, equal. Second Class: J. N. Brown of London and C. C. Clarkson of Leicester. Midwifery.—Senior class: gold medal, A. Gaskell of Dartmouth; silver medal, P. H. Stirik of Wolverhampton. Junior class, silver medal, A. W. Kirkpatrick-Picard of London; certificates, 2\*, Palemon Best of St. Ives; 3\*, T. B. Stedman of Leighton Buzzard; 4\*, A. J. Lang of Southport; 5\*, H. J. Price of New Malden; 6\*, G. P. James of Llanely. Medical Jurisprudence.—Gold medal, C. M. Spain of London. Hygiene and Public Health.—Silver medal, J. Wilkie of London. Second Class: J. Rannie of Aberdeen. Clinical Medicine.—Junior Class: Fellowes Silver Medal, W. D. Jones of Chipping Sodbury; certificate, 2\*, A. P. Nuttall of Bury. Second Class: A. W. Kirkpatrick-Picard of London. Third Class: W. E. Kirby of London. (\*Obtained the number of marks qualifying for a prize.)

## Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET OFFICE, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ARCHER, E. J., M.B., C.M. Dub., has been appointed, *pro. tem.*, Medical Officer for the Second Sanitary District of the Southampton Incorporation, *vice* Archer, deceased.

BAILEY, T. C., L.R.C.P., L.M. Edin., M.R.C.S., has been appointed Medical Officer for the Crewe Southern Sanitary District of the Nantwich Union.

BOSTOCK, J., M.R.C.S., has been appointed Medical Officer for the Wymeswold Sanitary District of the Loughborough Union.

BRATTON, J. A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for Ewell, of the Epsom Union, *vice* Barnes, deceased.

CARNELLEY, M., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Gotham Sanitary District of the Basford Union.

COWAN, RICHARD HAMILTON, M.R.C.S., L.S.A., has been appointed Honorary Medical Officer to the Royal Albert Edward Infirmary, Wigan, *vice* R. F. Woodcock, deceased.

DALISON, BERNARD E., has been appointed Medical Officer and Public Vaccinator for the Puddletown District of the Dorchester Union.

DIGBY, C. A., M.D., B.Ch., D.S.M., L.M.R.C.P. Irel., has been appointed Medical Officer for the Ticehurst Sanitary District of the Ticehurst Union.

FORRESTER, R. A. P., M.B., C. M. Edin., has been appointed Health Officer for Wycheepford, Victoria, South Australia.

FRANCIS, ERNEST EDWARD, M.R.C.S., L.S.A., has been appointed Surgeon to the Assam-Bengal Railway.

HAMILTON, R. H., L.R.C.P., L.M., J.R.C.S. Irel., has been appointed a Public Vaccinator for the District of Mount Pleasant, South Australia.

HOOVER, MARSHALL, L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer for the Codner Park Sanitary District of the Basford Union.

HOUSLEY, J., M.D. St. And., M.R.C.S., has been reappointed Medical Officer of Health for the East Bedford Rural Sanitary District.

JACKSON, R., M.B., C.M. Edin., has been appointed Deputy Medical Officer for the Township of Sutton, St. Helen's, Lancashire.

JEFFREYS, JAS. G., L.S.A. Eng., has been appointed a Public Vaccinator for the District of Naseby, New Zealand.

KEMPE, C. M., M.R.C.S., has been reappointed Medical Officer for the Port of Shoreham.

MULLALHY, WM. T., M.D., M.Ch., L.R.C.P. Irel., has been appointed Health Officer for the Shire of Ballarat, Victoria, Australia.

PHILLIPS, GEO. G. O., L.R.C.P. Lond., M.R.C.S., has been appointed a Public Vaccinator, and also Health Officer for the Sire of Heidelberg, Victoria, Australia.

PURVIS, GEO. CARRINGTON, M.D., B.Sc. (Pub. Health) Edin., has been appointed Assistant Medical Officer of Health (Temporary) to the Port of Leith.

RICHARDSON, A., M.D. Brux., L.R.C.P. Edin., M.R.C.S., has been appointed an Honorary Medical Officer of the Port Augusta Hospital, South Australia.

WARD, A. A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Christchurch Sanitary District and the Branch Workhouse of the Parish of St. Giles, Camberwell.

WILLIAMS, G. R., L.R.C.P., L.M., J.R.C.S. Irel., has been appointed Medical Officer for the Seventh sanitary District of the Depwade Union.

YOUNG, RICH. W., M.R.C.S., L.S.A., has been appointed Government Medical Officer and Vaccinator for the Lower Clarence River District, New South Wales.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BERKSHIRE COUNTY COUNCIL.—Lecturer on "Hygiene." (Apply to Mr. Colburn, Organising Secretary, 6, Russell-street, Reading.)

BRIGHTON THROAT AND EAR HOSPITAL, 23, Queen's-road, Brighton.—Non-resident House Surgeon. Salary at the rate of £50 per annum.

CHELSEA HOSPITAL FOR WOMEN, S.W.—Clinical Assistant.

CHARING-CROSS HOSPITAL MEDICAL SCHOOL.—Lecturer on Organic Chemistry. Minimum remuneration £100 per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Pathologist. Salary 100 guineas per annum. (Applications to the Secretary, 21, Finsbury-circus, E.C.)

CLAYTON HOSPITAL AND WAKEFIELD DISPENSARY, Wakefield.—Junior House Surgeon. Honorarium £40 per annum, with board, lodging, and washing.

COUNTY BOROUGH OF STOCKPORT.—Medical Officer of Health for the District of the Borough, and to the Infectious Diseases Hospital, and Surgeon to the Police Force, at a salary at the rate of £400 per annum. (Applications to the Town Clerk, Lord-street, Stockport.)

COVENTRY AND WARWICKSHIRE HOSPITAL.—Assistant to the House Surgeon, for six months. Honorarium £15, with board, residence, washing and attendance (exclusive of beer, wines and spirits.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physicians.

Huddersfield Infirmary.—Honorary Physician.

INVERNESS DISTRICT BOARD OF LUNACY.—Medical Superintendent for the Inverness Asylum. (Applications to Mr. E. Davidson, Queens-gate-chambers, Inverness.)

KENT AND CANTERBURY HOSPITAL.—Assistant House Surgeon. Salary £50 a year, with board and lodging.

KENT COUNTY LUNATIC ASYLUM, Barming-heath, near Maidstone.—Third Assistant Medical Officer. Salary £175 per annum, rising £5 per annum up to £200, with furnished quarters, attendance, gas, washing, garden produce and milk. (Applications to Mr. Howlett, 9, King-street, Maidstone.)

M. C. L., care of J. W. Vickers, 5, Nicholas-lane, E.C.—Qualified Medical Man, to proceed to Mexico as Medical Superintendent of a Mining Company. Salary £300 per annum.

PORTLAND HOSPITAL FOR ACCIDENTS, Blackwall, E.—Senior House Surgeon. Salary £100 per annum, with board &c.

READING AMALGAMATED FRIENDLY SOCIETIES' MEDICAL ASSOCIATION. Assistant Medical Officer. Terms £70, in-door. (Applications to be made to R. M. B., Dr. Stansfield, 80, Southampton-street, Reading.)

ROYAL UNITED HOSPITAL, Bath.—House Surgeon for one year. Salary £60 per annum, with board, lodging and washing.

## Births, Marriages and Deaths.

### BIRTHS.

GLYN-GRIFFITH.—On Aug. 20th, at Allahabad, North-West Provinces, the wife of Dr. R. Glyn-Griffith, Senior Surgeon, E.I.R., of a son.

HEDGES.—On Sept. 26th, at 18, Lake-street, Leighton Buzzard, the wife of J. A. Hedges, M.R.C.S. &c., Medical Officer to Local Board, of a son.

JOINSON.—On Sept. 25th, at Mickleton, Campden, Gloucestershire, the wife of James Bovell Johnson, M.D., of a daughter.

PRATT.—On Sept. 27th, at Weedon, Northamptonshire, the wife of W. Sutton Pratt, L.R.C.P. Lond., M.R.C.S., of a daughter.

SCOTT.—On Sept. 21st, at Heathfield, Bromley, Kent, the wife of John Scott, B.A., M.B., M.R.C.S., of a son.

### MARRIAGES.

FINLAYSON-SELLICK.—On Sept. 22nd, at St. Andrew's, Gibraltar, Henry W. Finlayson, M.B. C.M., Surgeon, E.N., to Charlotte Elizabeth, only daughter of Stephen Sellick, Kensington.

KEYS-WELLS-LOWNDES.—On Sept. 21st, at Little Comberton, Dr. Ernest Neville Keys-Wells, of White Parish, near Salisbury, to Grace Eleanor, second daughter of the Rev. E. S. Lowndes, M.A., Rector.

MURPHY-LLEWELLYN.—On Sept. 22nd, at St. Stephen's Church, East Twickenham, Dr. H. Howard Murphy to Annie, daughter of the late Thomas Llewellyn, Esq.

TRANTER-CARPENTER-FROOM.—On Sept. 24th, at St. Mark's Hamilton, terrace, P. Tranter-Carpenter, M.R.C.S., &c., of Stann Creek, British Honduras, to Amelia (Lillie) Froom, fourth daughter of the late Alfred Froom, Esq., of Malda-vaie, W.

### DEATHS.

ANDREWS.—On Sept. 21st, Henry Charles Andrews, M.D., M.R.C.S., L.S.A., L.M., late of Addison-terrace, Notting-hill, London, aged 65. Friends will kindly accept this intimation.

COMPTON.—On Sept. 20th, at Pelham House, Poole, Francis Charles Compton, M.R.C.S., L.R.C.P., aged 38.

HAIME.—On Sept. 20th, at Barnsley, Yorkshire, W. C. Haime, L.R.C.P., L.R.C.S. Edin.

HESLOP.—On Sept. 21st, at 92, Windsor-road, Southport, Robert Heslop, L.R.C.S.E. and L.S.A., Consulting Surgeon to St. Mary's Hospital, Manchester, aged 68 years.

LONGSTAFF.—On Sept. 23rd, at his residence, Butterknowle, Wandsworth, George Dixon Longstaff, M.D., in his 94th year.

MACGOWAN.—On Sept. 15th, in London, Thomas Newall Macgowan, M.B., aged 22.

PRESTON.—On Sept. 24th, at Kilderminster, II. T. Preston, M.D. Abord., C.M., M.R.C.S.

RICHARDS.—On Sept. 25th, the result of an accident, Robert Crout Richards, M.R.C.S.E., L.R.C.P.I., L.M., of Orchard House, Shotley Bridge, aged 40, son of Alfred Richards, Portreath, Cornwall.

RUSSELL.—On Sept. 27th, at Worthing, John Russell, Surgeon, aged 62, late of Newcastle-on-Tyne.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages and Deaths

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

Monday, October 3.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.80 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.  
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.  
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.80 P.M., and each day at the same hour.  
 CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.80 P.M.; Thursday, 2.80.  
 HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.  
 METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.  
 ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.  
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.  
 UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

Tuesday, October 4.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.  
 GUY'S HOSPITAL.—Operations, 1.80 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.80 and Thursday at 2 P.M.  
 ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.  
 ST. MARK'S HOSPITAL.—Operations, 2 P.M.  
 CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.  
 WESTMINSTER HOSPITAL.—Operations, 2 P.M.  
 WEST LONDON HOSPITAL.—Operations, 2.80 P.M.  
 ST. MARY'S HOSPITAL.—Operations, 1.80 P.M. Consultations, Monday, 2.80 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.80 P.M. Electrotherapeutics, same day, 2 P.M.

Wednesday, October 5.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.  
 MIDDLESEX HOSPITAL.—Operations, 1.80 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.  
 CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.  
 ST. THOMAS'S HOSPITAL.—Operations, 1.80 P.M.; Saturday, same hour.  
 LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.  
 ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.  
 SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations 2.80 P.M.  
 GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.80 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.  
 ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.  
 CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.  
 OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Galabin, Dr. McAdam Eccles, Dr. Horrocks, Dr. Rutherford, Dr. Amand Rowth, and Dr. Cullingworth.—Dr. Cullingworth: The Value of Abdominal Section in certain cases of Pelvic Peritonitis.

Thursday, October 6.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.80 P.M. Ophthalmic Operations, Friday, 1.80 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

Friday, October 7.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.  
 WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital).—8.30 P.M. Opening Address by the President (Mr. Swinford Edwards): Urinary Surgery of the Present Day contrasted with that of Twelve Years ago.

Saturday, October 8.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

NOTE-TAKING AND MEDICAL STUDY AND PRACTICE.

THE *Phonetic Journal* of the 24th ult., commenting on an article in our Students' Number entitled "Notes and Note-takers," says:—

"THE LANCET points out that many students know a little shorthand, and wisely recommends them to improve their shorthand for the purpose. But as regards those students who have no knowledge of shorthand, it remarks that they will speedily acquire an abbreviated form of longhand which will probably serve their purpose. We do not share the opinion. To acquire a serviceable method of abbreviated longhand is a long, laborious process, and the notes taken in it when acquired are usually slovenly and illegible, as must be the case when an attempt is made to follow a rapid speaker by means of longhand, however abbreviated, and even when all that is sought to be taken down is a sentence here and there. But the ordinary run of abbreviated longhand, that which the amateur note-taker develops himself, seldom represents a saving of more than 4 or 5 per cent. of the time that would be required to write in full longhand. On an emergency it breaks down entirely. The best advice to every medical student who does not know shorthand is that he should devote some of his time to mastering an art that eminent medical practitioners declare to have proved so valuable to them. With that knowledge they will be enabled to take notes with ease and comfort—notes that they will be able to read without hesitation whenever they desire to do so. With the other piece of practical advice in the article in THE LANCET—namely, that students should secure well-bound substantial note-books—we thoroughly concur. They should be well bound and substantial in order to be available for reference in future years. Stress is laid in THE LANCET article upon the importance of note-taking as a means of cultivating in student days certain habits that are conducive to success in later life. The educational value of the practice of note-taking is too often lost sight of; but, as THE LANCET writer points out, the student who takes notes regularly is likely to develop the habit of punctuality. Like the professional note-taker, who is rarely behind time, the student who takes notes systematically will make a point of being present at the commencement of a lecture. He will also attend with more regularity for fear of missing one lecture of a course, and perhaps having to make good the gap by a prolonged study of books. The practice of note-taking tends to strengthen the power of continuous attention and thus to develop a faculty of the greatest service in every walk of life. It also helps to promote thoroughness. The student who has acquired these qualities in his student days goes forth into the world with a mental equipment of useful habits that are as valuable to him as the knowledge he has gained. To take his notes comfortably, clearly, and so that they may be easily referred to and read in after years the student must have mastered shorthand, and the one defect that we notice in an otherwise admirable article is that this point is not emphasised so strongly as it deserves to be. The medical man who has made himself proficient as a phonographic note-taker in his early days gets so accustomed to rely upon shorthand that he instinctively uses it whenever he has need to make notes, and in his professional work he has abundant need to do so. Therefore it is with confidence that we urge upon all who are, or who propose to become, medical men to learn shorthand and to make it a daily companion of their studies."

*Aqua Pura* (Biggleswade) should consult an article which appeared in THE LANCET of Sept. 12th, 1891, page 628.

## THE LIMPET'S ADHESIVE POWER.

*Mr. J. Lawrence Hamilton*, who has been continuing his experiments on the adhesive power of the limpet, informs us that he has found that whilst a force of 35 lb. is required to remove a living limpet from the place to which it has affixed itself, 25 lb. suffices to displace a limpet immediately after poisoning with corrosive sublimate, and that a force of 9 lb. will detach the limpet twenty-four hours after death. From the experiments which he has made he thinks he may, perhaps, be justified in concluding that while some portion of the adhesive power may or may not be due to atmospheric pressure, a very considerable amount, if not the whole, is dependent upon the power of the creature to throw out a very tenacious substance. In favour of the latter view is the definite evidence of the absence of a vacuum beneath the foot, or of any mechanism whereby such a vacuum might be produced—such, for instance, as is seen in the suckers of the tentacles of octopi &c., and the fact that the adhesion continues after the death of the animal.

*Mr. R. V. Boyle*.—We are not aware that any medical practitioner has devoted more attention to the ailments arising from bicycle riding than to those arising from any other cause. Any properly educated physician or surgeon would be able to treat such troubles.

*Mr. D. T. Richards*.—We think our correspondent would be well advised by delaying—for a time at least.

*Mr. R. N. Ingle* (Jersey) is thanked for his suggestion and appreciation.

## HOSPITALS AND PRIVATE PRACTICE.

To the Editors of THE LANCET.

SIRS,—Much has been said and written about abuse of hospitals, but very little about the grievous abuse of private practice. When deductions are made for the hours consumed in hospital attendances, committee meetings and the various educational, public, social and semi-political engagements which make up the daily round of duty of a hospital physician or surgeon in London, the time at his disposal for seeing paying patients and thereby making a professional income is strictly limited. And yet most men in large practice are called upon to give a considerable portion of their time to seeing patients gratuitously. Many such patients are, it is true, medical men or those dependent upon them, or other worthy persons to whom it is at once a pleasure and a privilege to be of service; but a large number do not belong to this class, and would themselves be sorely puzzled to explain to their personal friends on what grounds they consider themselves entitled to receive medical advice for nothing.

Last week I received a letter from a gentleman asking me to see at home a young woman in whom he was "interested." I replied that I was about to resume hospital work and should be happy to see the young woman at the hospital. Upon this his wife sent the following touching appeal. I should perhaps state that, so far as I know, the only ground on which this lady could base her claim to her "favour" is that eleven years ago, at the request of her medical attendant, I performed an operation upon her for a very reduced fee, and that she subsequently paid me several professional visits, for which no honorarium was ever tendered.

"Sunday, Sept. 25th.  
"DEAR MR. —,—I am going to ask you a great favour; it is this. Would you mind the young woman my husband wrote to you about coming to see you in Harley-street, instead of going to either hospital? The fact is I am so nervous just now about infection, both for the girl (who is in my service) and the fear of her bringing any germ from an out-patient's department. She is a good girl, and I am most anxious to know your opinion about her. Once more asking forgiveness for troubling you,  
"I am, sincerely yours, "\_\_\_\_\_"

Ought I to have succumbed? I did not; but answered that as the demands upon my gratuitous services were already almost unbearable, and as in order to see a patient gratuitously I should have to decline one who would pay, I regretted I was unable to accede to her request, adding that as regards the danger of infection neither she nor her maid would at the hospital encounter any greater risk than my wife and children were exposed to every time I attended hospital.

I am, Sirs, yours truly,

Sept. 20th, 1892.

F.R.C.S.

*Mr. F. P. Trench*.—In the little calendar or register published by the Medical Council of British Columbia in May, 1892, it is stated that "during the year there shall be three regular meetings and three examinations held, beginning on the first Tuesday of May and September and the second Tuesday of January." The examination papers for May, 1892, are appended.

*An Advocate for Registration of Midwives*.—Our columns are intended for members of the profession. Our correspondent's letter is not without prejudice and admits of refutation.

*G. V. (Kidderminster)*.—We regret that we must decline to reply to our correspondent's first question. With reference to the second he should address the publisher.

*M.*—The paper shall have early attention.

## PUBLIC HEALTH AND LEGAL RESTRICTIONS.

To the Editors of THE LANCET.

SIRS.—You will much oblige me by answering the following questions through the medium of your valuable journal. In cases of infectious disease—(1) Is there any law to prevent the father of a patient, or the mother, going to work, supposing the father to work at a laundry or something of that kind? (2) Supposing the mother to be a midwife, can the medical officer of health restrain her from attending cases till after a certain time? (3) Can the children be restrained from playing or otherwise mixing with other children?

I am, Sirs, yours faithfully,

Grays, Sept. 21st, 1892.

SIDNEY H. SNELL, M.D.

\*\* There is no law directly covering any one of the three questions raised. The only assistance which might be looked for from the law is provided by Section 126 of the Public Health Act (1875), by which it is enacted that "any person who gives, lends, sells, transmits or exposes, without previous disinfection, any bedding, clothing, rags or other things which have been exposed to infection from any such disorder shall be liable to a penalty not exceeding five pounds." This provision includes clothing exposed to infection; but we doubt whether the clothing worn by persons attendant on, or otherwise coming in contact with, the sick would be included in its meaning.—ED. L.

THERE are many ways of procuring pure water besides that of filtering. M. Babes has proposed a method which consists in precipitating the minute organic ingredients contained in the water by shaking up the latter with iron filings, while a current of air is passed through the liquid. The novelty of this method lies in the use of the iron filings, which, in contact with the air, undergo a certain oxidation; but the general principle, as Dr. De Santi demonstrated before the Société Biologique of Paris, has long been known and practised, particularly in localities where the water is impure and unwholesome. In Southern Algeria and in Cochín-China the natives add to the suspected water a trace of alum; then they shake it, let it stand, and pour off the liquid portion. In the case of iron filings, however, probably the oxide formed by contact with air effects in addition oxidation of the organic matter.

*Advertising Handbills*.—Some of the bills &c. are twelve months old. We should have more recent evidence.

*New Subscriber*.—We think Ellis's plates are the best for the purpose.

## A TROUBLESOME SKIN AFFECTION.

To the Editors of THE LANCET.

SIRS,—I should be very glad if any of my brother practitioners who have met with a similar case to the following, and have treated it successfully, would give me the benefit of their experience.

A young married lady, twenty-six years of age, is troubled with severe, intermittent attacks of what I believe to be urticaria, which is developed whenever she goes out into the air, and more especially if there is much sunshine; the rash makes its appearance on all exposed parts—viz., face, neck and hands—when severe spreading over the chest and occasionally on other covered parts of the body. It is accompanied by intolerable itching, lasting from half an hour to two hours, and generally leaves severe headache after each attack. The rash eventually bears the characters of an ordinary attack of urticaria, following poisoning by mushrooms &c., and when seen for the first time would be put down to this cause. Constitutionally, she enjoys fairly good health, suffers at times from slight dyspepsia, is perfectly regular, and of constant habits. I have treated her, with especial reference to her digestive organs, with alkalies, bismuth, arsenic, liquor potassæ, bromide of ammonia, citrate of caffeine and nux vomica, but with virtually no real relief. Change of air seems temporarily beneficial only. Any suggestions will be most gladly received by  
Yours truly,

Sept. 26th, 1892.

PERPLEXED.

Justice should, if satisfied with his own diagnosis of the case, press for payment. His claim is not to be decided by the different opinion of the medical officer of health. The time which had elapsed does not affect the legality of the claim.

*Dr. Max Defrenne* (Antwerp) is thanked.

## SOUTH AFRICA.

To the Editors of THE LANCET.

SIRS.—Can any of your readers kindly inform me what supply of drugs, instruments &c. it is necessary for a surgeon about to settle in South Africa to take with him? I am, Sirs, yours faithfully,  
September, 1892.

W. B.

To the Editors of THE LANCET.

SIRS.—Can any of your readers who are well acquainted with the climatology of South Africa inform me of the districts best suited to a patient suffering from bronchial asthma?

I am, Sirs, yours faithfully,

Sept. 27th, 1892.

MEDICUS.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Alderson, London; Dr. Armstrong, Newcastle; Mr. Wm. Anderson, London; Dr. F. F. Anson, Whitehaven; Mr. Bond, London; Messrs. Burgoyne and Co., London; Dr. Bagshaw, St. Leonards; Messrs. Battle and Co., Paris; Mr. Brown, London; M. Berthier, Paris; Mr. R. Fitzroy Benham, London; Dr. G. C. Bright, Switzerland; Mr. T. B. Browne, London; Mr. W. W. Brydon, London; Dr. W. H. Broadbent; Dr. John Boyd, Llanamman; Dr. Barnett, Burton-on-Trent; Messrs. Cassell and Co., London; Mr. R. B. Carter, London; Messrs. The Publisher cannot hold himself responsible for the return of testimonials &c. sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

# “LANOLINE,”

The Discovery of Professor LIEBREICH,

WILL REPLACE THE

## NATURAL FAT OF THE SKIN,

AND IS WIDELY

Prescribed by Physicians and Surgeons for all Ointments,

AS IT

is aseptic;

does not turn rancid;

is rapidly absorbed by the skin;

AND

can be mixed with any proportion of water.

A striking illustration of the power of “LANOLINE” of resisting influences which tend to decompose ordinary fats is afforded by some experiments carried out in 1890 by Surgeon-Major M. G. KING, with the design of obtaining a preparation of vaccine lymph which should withstand the destructive action of the heat in India. KING tried preparations with glycerine, boroglycerine, soft paraffin and “LANOLINE.”

The mixtures containing glycerine decomposed in a week, those of boroglycerine in a fortnight and sometimes sooner, while 1 part of lymph with 4 parts of “LANOLINE” kept completely for at least 40 days

**Dr. A. GOTTSTEIN** showed that “LANOLINE” not only was free from germs, but also **PREVENTED** their growth.

**Dr. S. ECCLES** said that he preferred “LANOLINE” to soft paraffin and other preparations.—**BRIT. MED. ASSOC.**, 1887.

**Dr. W. G. SMITH** proves the virtue of “LANOLINE” in acne and chapped hands.—**BRIT. MED. JOUR.**, June 12th, 1886.

**Dr. SHOEMAKER** describes “LANOLINE” as a mild and soft ointment, valuable for a great number of obstinate skin diseases.—**BRIT. MED. ASSOC.**, 1886.

**Professor ROSENBACH** speaks highly of “LANOLINE” for the prevention and relief of decubitus.

**Prof. NILS O. GADDE** prescribes “LANOLINE” in Frostbites with great success.

**Dr. R. KLEIN** calls attention to the value of a “LANOLINE” cooling ointment containing 50 per cent. water for the successful relief of the itching of measles, scarlatina, chicken-pock, or of any origin.

**Dr. STELLWAGON** considers “LANOLINE” indispensable in psoriasis.

**Dr. NEWTH** treated obstinate ulcers of the irritated kind with “LANOLINE” ointments.

**Dr. MACKEY** used it in all skin diseases, and particularly in chronic joint affections of rheumatic origin.—**BRIT. MED. ASSOC.**, 1886.

Physicians should always prescribe “LANOLINE” diluted with about one-third of its weight of soft paraffin; or they can prescribe this mixture of “LANOLINE” and soft paraffin under the name of

## “UNGUENTUM LANOLINI.”

Introductory Address

ON THE

METHODS, OBJECTS AND AIMS OF STUDY.

*Delivered at St. Mary's Hospital at the opening of the Medical Session on Oct. 3rd, 1892.*

By ARTHUR P. LUFF, M.D. LOND.,  
PHYSICIAN TO THE HOSPITAL.

It has fallen to my lot to-day, in accordance with our custom here, to address a few words of welcome, counsel and encouragement to those of you who are now entering upon your medical studies in this school. Diffident as I feel of my power to do justice to the present occasion, especially when I reflect upon the names of those who have preceded me in the performance of this function, yet in one respect I feel no hesitation, and that is in the heartiness with which I congratulate you on your choice of a profession, and in the welcome which, in the name of my colleagues, I extend to you upon your entry into this school. Rightly worked at, the profession that you have chosen is indeed a noble one. Of it Thomas Carlyle has written: "What profession is there equal in true nobleness to medicine? He that can abolish pain and relieve his fellow mortal from sickness, he is indisputably the usefulest of men. Him savage and civilised will honour." If, however, you are ambitious of riches or of ornamental worldly honours, then you have not chosen a profession which is likely to bring you a plethora of wealth or titles; but if you are looking to the higher aim of human life the desire to minister to the well-being of the human race, at the same time that you earn for yourselves a fair though modest livelihood, then you will not, I think, ever have cause to regret your choice. In no profession are there such great and constant opportunities of doing the good work of relieving suffering and soothing sorrow as in ours, and in the pursuit of this activity for the happiness of others you will attain to the best form of happiness for yourselves—a reward far better than those of riches or of titles. I propose this afternoon to deal with the objects of your studies and work by briefly considering (1) the methods you must adopt here for the acquisition of the requisite education and training that shall fit you for the subsequent discharge of your professional duties as medical men; (2) the opportunities that are offered by your work for the moulding and development of the moral character, so as to fit you for the discharge of the ethical duties both of men and physicians; (3) the means offered you for the training of your powers of observation and thought, so that those of you who rightly avail yourselves of the opportunities may go forth fitted to become explorers and interpreters in the fields of medical science.

With regard to your studies here, let me say at once that though but average mental power and ordinary ability are all that are requisite for the successful prosecution of your studies, for the passing of your examinations, and for the after practice of your profession, yet the one thing that is indispensable is industry. I must honestly impress upon you that it is a laborious career which you have chosen, and one to which you must come with the plain, straightforward object of bringing all that science can teach you to the relief of a suffering humanity. Without determined, steady application no success of any real worth can come to the medical student of the present day. In your work you will find that the race is not always to the swift, and that it is not so much the possession of speed as of staying power that will serve you best in the career that is now before you. If any of you have come here with the idea that the life of a medical student is to be one mainly of pleasure, or with the prospect that you will be able to devote a large share of your time to the gaieties of London life, and a small share of your time to work, I say to such—at once abandon that idea, or at once abandon a career for which you can never be fitted. There is no place for the Bob Sawyer here; the days of walking the hospitals are over and past; these are the days of working in the hospitals. Once more let me repeat that steady application and perseverance in your work are the main factors for success

No. 3806.

here; the possession of exceptional ability is not necessary, but should there be, as I trust there are not, any now joining who are contemplating a life of indolence and pleasure, to such I would say at once and emphatically—abandon hope all such who enter here. I beseech you at this the outset of your medical careers to consider carefully and earnestly the responsibilities that you are incurring and will have to incur. Your subsequent professional careers and actions will be in great measure the result of the industry you display during the next five years. I beg of you to so direct your actions that no apathy in your work, no carelessness in your studies, no neglect of the business of your profession, may be the cause of your ever failing in the future to administer rightly the relief to suffering beings, or you will assuredly have to bear with you, through life, the burden of a conscience that will be constantly reminding you of precious lives lost through your want of skill, of misery brought to many a home as the result of your neglect, of the conversion, by your own fault, of capabilities entrusted to you of doing good into opportunities of doing evil.

I address you as one who has comparatively recently travelled over the part of the road you are now about to take, and as one acquainted with its windings let me point out to you the direction in which you should travel and some of the difficulties that have to be overcome. Do not think that I am contemplating the wearying or the worrying of you with the experiences of my life. I am not, and for the good reason that I am fairly convinced that it would not be of the least use to you. Experience you must acquire for yourselves, and the higher the price you have to pay for it, the greater the suffering through which you learn the more valuable will it be in aiding you to guide and direct your lives. It is doubtless a wise dispensation that individuals profit but little by the experience of other individuals. To those of you coming straight from school or college there will open up what I venture to prophesy will be a delightful change in the nature of your work. At school and college education consists too much in the study of the writings of the past, with a corresponding neglect of the study of the marvellous works of nature. There the ornamental has been given precedence to the useful; here you will find the order reversed. I do not wish to underrate the value of a classical education; it is doubtless, as society goes, the hall-mark of a certain social rank, but I do regret that in our preparatory schools and universities scientific education and training are so subordinated to that which is used more for extrinsic effect than for intrinsic aid in the actions of life.

At the outset of your medical studies you will probably be surprised, and perhaps alarmed, at the diversity of the subjects with which you have to form some acquaintance, and with the wide range of medical education of the present day. The relationship of some of these subjects to your future work and their direct or indirect utility in the practice of your profession may not at first be apparent to you. Let me assure you, however, that the curriculum of study and work which you have to pursue, and which has been mapped out for you with much forethought and care is one that well comprises what is necessary for your training and future success. In the study of those departments of science which precede the direct study of medicine and surgery due regard has been paid to the relationship they bear to medicine and surgery, and though this relationship, and therefore their utility, may not at first be apparent to you, yet eventually you will surely recognise the mutual connexion existing between the various branches of your professional studies. Take, for instance, the subject of chemistry. No one, I presume, will deny that chemistry is a most important and useful science; but the question to you is not whether chemical knowledge is of worth, but what is its relative worth. Remembering how the time for the acquisition of knowledge is limited by our "span-long lives," we must necessarily be careful to employ that time to the best advantage, or, to use an expression of Bacon's, "we must determine the relative values of knowledges." This, I claim, is well done for you in the curriculum of work that has been drawn up for your guidance, and which you will have to faithfully follow here. Although we speak of physics, chemistry, biology, physiology &c. as sciences, do not think that they are distinct branches of knowledge, having no relation to each other. In nature there is no distinction between the so-called sciences; the distinction is a purely artificial and conventional one. It would be better that they should be spoken of as branches of science, for by science is simply meant organised knowledge. The study

of physics, chemistry and biology will prepare the way for, and lead you up to, the study of physiology, and so you will obtain the firm scientific groundwork for the study of the disorders of the human body, which is to be the field of your ultimate special work. Our forefathers adopted an entirely different system of medical training. With them a period of pupilage with a medical man preceded the studies of the medical school; so that the student of those days was first brought face to face with disease before he had learnt the facts and phenomena necessary for the comprehension of it. That, I venture to think, was a most baneful system; it was the building of the house on the sands of empiricism, instead of its erection on the rock of scientific knowledge.

Here let me point out to you that the training through which you have to go to thoroughly fit yourselves for the relief of suffering is one excellently adapted to intellectual development. In the medical school and in the hospital you will be brought face to face with facts, you will be taught to search out and learn for yourselves the truths of nature, and proceeding step by step in your observations, from simple to more complex phenomena, you will, by the inductive method of reasoning, learn the laws which regulate the order of nature. Nature does not deceive those who patiently and laboriously study her immutable laws, though from those who run counter to them she exacts a sure and certain retribution. At this the outset of your medical careers you are doubtless making good resolutions; you are doubtless determining to earnestly apply yourselves to the work that lies before you. That is well. But remember to carry those resolutions into effect. Bear in mind the words of Carlyle: "The end of man is an action and not a thought." I do not wish to underrate the value of good intentions—they are most valuable if followed by good actions. "Good intentions are at least the seed of good actions, and every man ought to sow them." It has been said that man has two lives—that of action and that of thought. Learn therefore the blending of thought and action in the practice of your profession; they are not separated, but related, for action is concrete thought. There are but three classes of men—the retrograde, the stationary and the progressive. To which of these will you belong? It is no use saying that during your first year here you can take it easy and enjoy yourselves, and that you will make it up later on. You never will make it up later on. I would therefore impress upon you at the outset the value of a proper method of disposing of both time and energy and advise each one of you to adopt some method or plan in your work. Commit to writing a time-table for your daily duties both here and at home and rigidly adhere to that time-table. Let your reading time for each evening be arranged so as to rightly apportion your hours of work to the different tasks and subjects. You will not only by such method get through more work than you otherwise would, but your knowledge, if thus systematically acquired, will be more accessible to you when required for use. A writer of distinction says that there are two species of so-called practical minds. One sort of mind is constructed according to the carpet-bag pattern, where nothing is put in any order, and, to find any article, everything else has always to be turned out. The other is the museum sort of mind, in which every specimen is arranged and labelled in proper sequence, and whatever is wanted is always easily found. As a finish to the daily work there is a very useful rule recommended by Pythagoras—to review every night before going to sleep what we have done during the day. This daily settling of the debit and credit account will give you a clear idea of how you stand. But do not devote all the time given to study to the mere learning and ingestion of facts; some part of the time should be devoted to the careful consideration of them—to the processes of mental digestion. The acquisition of knowledge is not everything—what is more important are the digestion and organisation of knowledge, so as to adapt it to the practical uses of life; and for this digestion and organisation time and spontaneous thinking are required. As Humboldt remarks, "the interpretation of nature is obscured when the description languishes under too great an accumulation of insulated facts." Side by side with the acquisition of facts should go the cultivation of the power of observation. I cannot too strongly impress upon you the importance of observing for yourselves, and you will have manifold opportunities of doing so if you will only avail yourselves of them. The accumulation of the occurrences that you observe will constitute your experience, and from such experience, aided by your reasoning faculties, will issue

your actions. The more you observe the more enjoyable will life, in the fullest sense of the term, become. But in connexion with your studies you will necessarily find the acquisition of many of the details wearisome, and you may be tempted to regard some of those details as useless and trifling. It is not so.

"Think nothing trifling, tho' it small appears;  
Sands make the mountains, moments make the years,  
And trifles—life."

Schopenhauer says: "A man shows his character just in the way in which he deals with trifles—for then he is off his guard." Do not be either surprised or dismayed if you at times feel a spirit of despondency arising at the thought that apparently you are making no progress, that however hard you may work little or no headway seems to be made. Remember that it is frequently impossible to detect your progress day by day. The knowledge is surely being acquired, and, if you persevere, I venture to affirm that no one will be more surprised than yourselves at the result of your efforts. Honest work is of all things the most ennobling, and the greatest stimulant and the fullest delight in life come from the struggle with and the overcoming of difficulties.

"Strive, endeavour; it profits more  
To fight and fall than on Time's dull shore  
To remain an idler ever.  
For to him who bares his arm to the strife,  
Firm at his post in the battle of life,  
The victory falleth never."

Moreover, let me remind you that the display of interest in your work and the energetic discharge of your duties constitute a great encouragement to your teachers and furnish a direct stimulus to them in their work of instruction. Nothing is more discouraging and depressing to a teacher than to see a student sitting in the lecture theatre or class-room looking bored and uninterested, and taking no notes—perhaps not even possessing a note-book. It requires no great gift of prophecy to foretell that man's future—there is written upon his brow failure in his examinations, failure in life. Bear in mind therefore that amongst the influences at work in a medical school and hospital like this, the influence for good or ill is not only from the teacher to the student, but that your lives affect and react on ours. We are, after all, only students together, the older ones helping the younger ones, the younger ones encouraging by their enthusiasm and earnestness the older ones. "It is by teaching that we teach ourselves, by relating that we observe, by affirming that we examine, by showing that we look."

Among your various studies, do not neglect one which is most important—the study of the human individual. Symptoms of disease must not be studied in an isolated manner, they have to be considered in connexion with the constitution of the individual and the circumstances under which they arise. Your success as doctors will not consist merely in the interpretation of symptoms, but in your recognition and appreciation of the peculiarities and idiosyncrasies which go to make the individual, and in your powers of adapting yourselves to a right comprehension of the different individuals with whom you have to deal.

The new five years' curriculum which has come into force this year will, I think, prove a boon to you, in that it will enable you to do thoroughly what it was almost impossible to accomplish under the four years' curriculum. With the exception of biology, no new subject is interpolated into this extended curriculum, but one most important and useful reform has been introduced, and that is that a certificated course of study at a fever hospital is now insisted upon as part of the curriculum. I rejoice at the institution of this reform, for it is most essential that you should obtain a practical knowledge of the principal infectious diseases before you go into practice, not only that you may diagnose them correctly and by their early recognition take means to prevent their spread, but also because under the Infectious Disease Notification Act that came into force in 1889 a power is placed in your hands which is almost the power of the *lettre de cachet*. There is one other reform which I trust we shall ere long see instituted, and of which those of you who are now commencing your curriculum will in all probability be able to avail yourselves five years hence, a reform which is sorely needed as a matter of justice and equity to the majority of London medical students, and that is the establishment of a university in London where the degree of Doctor of Medicine will be within the reach of all medical students, and where it can be obtained by a less rigorous series of examinations than the present somewhat

exclusive degree of the University of London. A Royal Commission has been appointed to recommend a scheme for establishing a new university, and I devoutly hope that their deliberations will shortly bear fruit.

So far I have referred only to your professional studies, but do not restrict your education to purely professional subjects and books. Let your reading be general, and through books cultivate the acquaintance of great minds. Just as by ascending to a height the view becomes broadened and the eye can take in so much more, so does general cultivation elevate the mind and give to it a broader and a grander view. Therefore fill up the leisure left by graver occupations with the different forms of lighter and pleasurable occupations, with the perusal of the works of novelists, of poets and with music. Do not crush beauty and poetry out of life. Allow the imagination and the emotions fair play. You will not be efficiently equipped for the discharge either of your professional or social duties if the acquirement of deep information on medical matters has been obtained at the cost of general culture in literature and the fine arts. Herbert Spencer says of the cultivation of literature and the fine arts: "As they occupy the leisure part of life, so should they occupy the leisure part of education." But however engrossed you may become in your studies, never lose sight of the necessity of carefulness of your health and of the need for daily recreation. The acquisition of knowledge is not the only thing needful. The first requisite to success in life is a healthy body, and the best brain is of little service unless there be sufficient vital energy to work it. Remember that success in the medical profession depends much on energy, not altogether on information. Never forget the great value of health as the chief and most important factor in happiness. In primitive times, when muscular power was the chief factor for success in life, the cultivation of the body was the main desideratum, and the cultivation of the mind was almost if not entirely neglected. Now the pendulum has swung perhaps too much in the opposite direction, and excessive devotion to mental education has resulted in a corresponding neglect of bodily education. We must thoroughly realise the fact that physical development underlies mental development, and that a high mental development can never be attained at the expense of the physical one. And here I am happy to say that at the medical schools recognition of this fact is well shown in the endeavour of our students to combine work with play, as illustrated by our various athletic and sports clubs. Some of the sports, however, such as football, cricket, rowing &c., are not immediately accessible, and therefore without the slightest intention of underrating the value of those sports, let me mention one which possesses peculiar advantages to the student residing in London and to the healthful influence of which, on my own life as a student, I can well testify—I refer to cycling. But I refer to rational cycling, not to the horrible exhibitions of cycling too frequently seen in our streets nowadays, not to the individual who, with crooked back and head dangling over the front wheel, tears along indifferent to the safety and comfort of others, and who is so aptly compared by the observant gamins of the London streets to a "monkey on a gridiron." I think too that it is time that we, as members of the medical profession, whilst advocating the immense benefits of athletic training, should raise our voices against the growing evils of athletic straining. A few days ago you might have read in the papers that a bicyclist rode 421 miles in twenty-four hours—that is, that, not allowing for any stoppages, an average pace of over seventeen and a half miles an hour had to be maintained for the twenty-four hours. What a frightful strain to subject the heart and vessels to, what a terrible overtaxing of the powers of the nervous centres, what a fearful price will assuredly have to be paid in the future for the vainglory of having established a *record*!

I have been a cyclist for sixteen years, and in my earlier athletic days I frequently associated with, and therefore had the opportunities of observing, young men who at that time stood prominent in the athletic world as champions and record-breakers, many of whom, alas, now sleep the long sleep, hurried prematurely to their graves by the insane desire for so-called fame of record-breaking and prize-winning.

I pass now from the question of physical training to say a few words concerning moral training. In the first place, with regard to your dealings with the patients in the hospital, be cheerful and kind in your manners to them, showing at all times that delicate consideration for the feelings of others

of which poor and rich are almost equally appreciative. The manners and address that you adopt towards the patients here will be those that will in great part remain with you when brought in contact with your private patients later on. But especially endeavour to be cheerful. It appears to me that in these days of competition and hurry men and women do not sufficiently cull the little wayside flower of cheerfulness. It will make you and others the happier if you will stoop and pick it as you trudge along the highway of life. With regard to the selection of your companions here, be slow and careful in forming acquaintances, for the character of these will probably affect your whole future career. You will, I hope, form many strong and lasting friendships here, but above all make yourselves pleasant companions for yourselves. "What a man has in himself is then the chief element in his happiness," says Schopenhauer. Self-discipline and self-control strengthen the moral fibre; self-improvement means not only self-elevation, but an addition to what should be our highest ideal—the perfection of humanity. In addition to learning the cure of disease and the alleviation of pain you learn here the laws of health, and therefore you will know, or should know, how to shape your lives so as to best conform to those laws; and it is by so conforming or not to them that you will set an example, good or bad, to others in the conduct of their lives, for every man's life, directly or indirectly, knowingly or unknowingly, affects those of others. The medical man should be a moral teacher, showing by the example of his life the lives that others should lead, for to him is given in a very high degree the opportunity of influencing the lives of those of his fellow creatures with whom he is professionally and otherwise brought in contact. There is a constant struggle between the sensual and the spiritual sides of ourselves, between the desire to do that which merely brings ephemeral pleasure or gratification and between that which the prompting of the better instincts tells us to be right and good. The outcome of these struggles must determine for good or ill our characters; according to the side on which rests victory is the position that we take, high or low, amongst our fellow men.

"Our little lives are kept in equipoise  
By opposite attractions and desires!  
The struggle of the instinct that enjoys,  
And the more noble instinct that aspires."

Remember always that it is only patient, hard work that can fit you for the discharge of life's duties—by such means only can you hope to attain to eminence in your profession. Do not think to ever attain it by some happy accident, by some stroke of luck. Believe not in luck, in chance. Those who ascribe the rise of an individual to luck do not think of or recognise the years of toil and self-denial, the struggles and the self-conquests, that have preceded the attainment of his present position. We should all endeavour to clearly recognise how great is the power which man may exert over his own destiny, the power as to whether out of himself he can raise a noble intellectual edifice or reduce himself to a moral and physical ruin. Do not delude yourselves, as so many do, by saying, "Circumstances have not favoured me; luck has not befallen me." Nothing of the kind!

"Man is his own star; and the soul that can  
Render an honest and a perfect man  
Commands all light, all influence, all fate;  
Nothing to him falls early or too late.  
Our acts our angels are, or good or ill,  
Our fatal shadows that walk by us still."

Bad actions, though unseen, though unknown to our fellow creatures, are not without influence on our lives. Evil actions, even if counteracted by good ones, still leave their marks—they are indelible. Perhaps it is well so. The memory of past misdeeds may prevent their repetition. Let me tell you a simple little anecdote. A boy whose resolutions were good but whose actions were frequently perverse was told by his father to go and drive a nail into the door-post for every bad act he committed. He shortly came to his father and with a sorrowful face informed him that there was a crowd of nails in the post. "Well, my son," replied the father, "for every good action you do henceforth go and pull a nail out." Some time later the boy came to his father and said, "The nails are all out; but, father, the marks are still there."

I lastly have to say a few words as to the opportunities that will occur to you for the training of your powers of observation and of thought. The work, and especially the clinical work, that you will do here is so arranged as to stimulate thought and to promote the cultivation of independence

of judgment. Knowledge and intellectual cultivation should be acquired side by side. By knowledge I mean the mere possession of truths; by intellectual cultivation, the acquired power of applying those truths. At the present time I think we may fairly say that Voltaire's satirical remark that an apothecary is a man who pours drugs of which he knows little into a body of which he knows less does not altogether apply to the physician of to-day. We are day by day learning more of the relations of the organism to its surroundings, and instead of endeavouring, as in the past, to treat the organism quite independently of its surroundings, in the recognition that a disturbance of these relations means disease and that a restored harmony between them is health, we are rising to a juster conception of our duties as healers of disease. One of the chief hindrances perhaps to development in our profession is an undue respect for so-called "authorities in medicine." The only sure road to truth is devotion to independent inquiry; and here let me remark that medical science is, in my opinion, markedly different from many other sciences, in that the field of original observation and work is open to all members of the medical profession, high and low, from the hospital physician and surgeon to the humblest general practitioner. Each one may alike contribute in his own way, by careful observation of disease, his share of new facts, or the fresh application of old ones; each one may help to increase the store of human knowledge; each one may render some assistance in advancing our powers of usefulness to our fellow creatures; each one may, by adding his increment, however small, to our knowledge, help to demonstrate the truth of Bacon's aphorism, that the end of knowledge is the well-being of the human race. To do this you must acquire the habit of recording your observations and not trust to unassisted memory. When you meet with symptoms in a patient that you do not understand do not be in a hurry to explain them; wait till you have investigated their causation. "Wise men investigate, while fools explain." An anecdote is told of a young doctor who, in his out-patient room, was learnedly explaining to the students around him the reasons why the right eye of the patient before him was somewhat different from the other. In the midst of a most erudite disquisition on the obvious nerve lesion which was responsible for the greater size of the right pupil, and for its not contracting to light, he was quietly interrupted by the patient with the remark that the eye he was referring to was an artificial one.

Here let me say a few words as to the important bearing on medicine of a branch of science for which I must own a personal attachment and predilection. I refer to chemistry. I am well aware that many of you will not be able to give more than a small share of your time to the study of chemistry, but to those of you who can spare the time to acquire a more extended knowledge of that science I venture to assert that you will become possessed of a factor most useful in the treatment of disease and most potent in aiding the discovery of some of the hidden secrets of the causation of disease. I do not think it is too much to expect that in the future we shall ascertain exactly how drugs act; that in connexion with many diseases, and especially in the case of the infectious diseases, we shall discover the poisons produced within the human body to which the symptoms of those diseases are due; and that, having discovered those poisons, the method of destroying them or rendering them innocuous by antidotes may be found. To those of you who can rightly use it I think it will be found that the light of chemistry will illumine many a dark corner of the still unexplored regions of the continent of disease. Therefore, whether in the direction of the discovery of new facts or in the fresh application of old ones, strive at forging a few links in the chain of progress for yourselves and so leave some marks on life's highway by which you may be remembered when dead and gone.

Although some measure of success has been attained of late years in the treatment of diseases of the individual, yet a much greater measure of success has been obtained in the prevention of the diseases of communities; and in the future preventive medicine will doubtless attain to a much higher degree of perfection. Small-pox has by vaccination and improved sanitation become almost banished from the realm of disease, and indeed in its old virulent form is now in this country simply a matter of history. Cholera, on account of the sanitary and preventive measures we adopt, is unable, as you have recently been made aware, to gain any foothold in this country. I take it as a truism that the prevention of disease is a much higher and grander aim of medical science

than its amelioration or cure. It therefore behoves us, in the furtherance of this enormously important work of preventive medicine, to look out that we are not left hopelessly in the rear by other countries, for to the advancement of what is so obviously of the greatest national importance a great obstruction has been offered in this country by what I am compelled to call the hysterical anti-vivisection movement. We, as members of the medical profession, are as much opposed to cruelty and to the infliction of unnecessary suffering on the lower animals as any members of the community, and I most thoroughly agree with the provisions in the Act of 1876, that painful experiments, with the rarest exceptions, must be made when the animals are unconscious under anaesthetics. I presume that even the most advanced opponents of so-called vivisection will agree that the lessening of the sum of suffering should be one of the highest aims of every human being, and if the abolition of much suffering and the saving of the lives of thousands of human beings can be secured even at the cost of the infliction of some pain on a few of the lower animals, is not such action not only justifiable but righteous? Moreover, the term "vivisection" is an erroneous one, and one that conveys an entirely false impression. The so-called vivisection experiments performed in this country are simply operations performed on animals, with the same skill, with the same antiseptic precautions, and with the same freedom from pain, as the operations practised on human beings, or else they consist of hypodermic injections which involve an infinitesimal amount of pain. The fact is that the utility and necessity for experiments and observations on animals cannot be rightly estimated by an unskilled public. I do not for a moment dispute that these sentimentalists are actuated by the most benevolent feelings, but I would ask them to direct some of their energy to the prevention of some of the cruel operations practised on animals to fit them for human food or labour, or to the altogether unnecessary and cruel suffering that is inflicted in the name of sport. If I, as a medico-legal expert and in the interests of justice, perform the almost painless experiment of injecting a poison into a mouse in order to observe its effects, the strong arm of the law can fall heavily upon me, although I am engaged in the vindication of the law; while at the same time the most horrible infliction of pain and suffering is permitted and even applauded at aristocratic pigeon-shooting matches, in pheasant preserves, in the hunting to death of terror-stricken foxes and tame stags; yea, in the last-mentioned instance it is even fostered and subsidised by the State. While these cruelties are allowed to continue the well-intentioned sentimentalists and opponents of so-called vivisection are straining at an infinitesimal gnat and swallowing a mammoth camel. Instead of impeding the advance of science, let them turn their attention to the suppression of this daily hecatomb of helpless animals, butchered to make an English holiday.

As you go through the course that has been arranged for you, and as you gain an increasing knowledge of the marvellous organisation and working of the human body, the more you learn, the more you will find that we are still unacquainted with what actually is life, that the sovereign reigning over all these states, the soul, is to us intangible, invisible. The more you learn, the more you will recognise that "there are more things in heaven and earth than are dreamt of in our philosophy." I deny the reproach that has been uttered, that where there are three physicians there will be found two atheists. To my mind it implies a very superficial acquaintance with science which can lead men to dogmatically assert that life is nothing more than the outcome of a series of chemical explosions taking place in certain cells, as if man were omniscient. To such the words written by one of the world's greatest philosophers will apply—"Though a small draught of philosophy may lead a man into atheism, a deep draught will certainly bring him back again to the belief of a God." Perhaps no other profession than ours better teaches and inspires the true religious feeling "that holiness is an infinite compassion for others; that greatness is to take the common things of life and walk truly among them."

Now my task is finished. I have endeavoured to give you, in a manner I know all too imperfect, a few words of encouragement and counsel at this the outset of your careers. Aim at aiding the great work of medical progress, aim at making your lives such that you will be ready, when the call shall come, to pay back again the talents you received, but ready also to pay them back with

usury. Believe me, if you will start with noble aspirations and will honestly endeavour to act up to them through life, then a successful, useful and honourable career is assured to you; and at the close of a life so spent, when the sun is setting and the twilight is gathering, there will come to each one of you the inestimable satisfaction of hearing the voice of conscience, the voice of God, saying, "Well done, thou good and faithful servant."

## Introductory Address

ON

### THE POPULAR IDEA OF THE DOCTOR TWO HUNDRED YEARS AGO AND NOW.

*Delivered at the Yorkshire College, Leeds,*

By WM. MITCHELL BANKS, M.D. EDIN.,  
F.R.C.S. ENG.,

SURGEON TO THE LIVERPOOL ROYAL INFIRMARY AND PROFESSOR OF ANATOMY TO THE UNIVERSITY COLLEGE, LIVERPOOL.

I wish to address myself specially to those among you who are my fellow medical students. I call you so purposely, for, however old we may live to be, and however many degrees or diplomas we may succeed in obtaining, we shall still be students of medicine to the end of our days. What am I to say to you? Shall I tell you of the nobility of the profession which you have joined? Shall I speak to you of its astonishing advances—advances so amazing that many like myself, who have seen some of the greatest of them, never cease to marvel at them, albeit a day hardly passes without our making practical use of them? Have I anything new to tell you about the best way in which you may conduct your medical education and fit yourselves for your future life? I was thinking of all these things the other day when I chanced to open an album in which were the portraits of many of my old teachers. I have always been a confirmed hero worshipper. I am sure it does a young man good to have his heroes and adore them and be enthusiastic about them and believe they can do no wrong. One of the faults I have to find with your modern Cambridge and Oxford man is that his motto is *nil admirari*. With him it is the height of good breeding to utter short sentences in a monotone, to preserve a frigid calmness, and to gaze with an equally stolid and bovine eye upon a drunken cabby or a transcendent genius. Only do his pulses quicken when he comes to the consideration of a shirt collar or "the nice conduct of a clouded cane." I confess I cannot bear a fellow who stifles his natural, hearty emotions like a man sitting on the safety-valve of a boiler. To return, however, to the album. As I turned over its leaves I came to the portrait of Syme and looked at the keen, shrewd, somewhat stern face of the Napoleon of surgery, whom in my youth I had constituted my surgical hero, and whose memory I still revere. A few pages further on I came to a beautiful head—a head almost classic in its outlines, and surmounting a tall and stately frame. I recalled the gentle, tender eyes, and the mouth, which, when in repose, gave to the rest of the countenance a tinge of melancholy, but which, in happy moments, could shape itself into a smile of surpassing sweetness. The face was that of Warburton Begbie, physician to the Edinburgh Infirmary. As a student one used to dream day dreams of the future. If ever I pictured myself as a great physician, when I looked closely into that picture it was the portrait of Begbie that I saw. So he became my medical hero. There are some here who will recall him as vividly as I do, and who can tell you for what good he influenced their lives by his own. Of his great eminence as a physician and of the quality of his contributions to scientific medicine I need say nothing. They are still fresh in the memory of those who are best able to estimate their value. As a teacher he had no rival in Edinburgh when I was a student. But while there have been many great physicians and many great clinical teachers, Begbie was not only both, but he was also the gentlest and most kindly of men. When he entered a ward a new light seemed to shine in the faces of the sick. In sooth, something to illuminate their lot was much needed in the dirty, dreary medical wards of the old Edinburgh

Infirmary. The very way in which he would put his hand on a patient's shoulder seemed to give the invalid comfort and strength. It was a great lesson to us young lads. We were full of health and life and hope; somewhat too apt to think that these sick people were only pathological curiosities and that we should never have trouble and disease like them. But there stood our master, who had seen much human suffering; who had had not a few trials to bear himself; and every day he taught us not only lessons in medicine, but lessons in courteous and considerate demeanour to the poor. I have always thought of him in my own mind as the gentle doctor, and I have always striven in the hospital ward and in the clinical theatre to imitate his example. People have often said to me that after many years of surgical work a man must become case-hardened. What a mistake! The more blood a surgeon sheds, the more readily do the tears come into his eyes.

As I was musing about my old master it occurred to me that he was essentially a product of the present day and the current of my thoughts took me back a couple of centuries, which is about as far back as we know anything real about the lives and the manners and customs of doctors. Before that time all is imagination and mystery. How could a comparison best be instituted between then and now? Probably by ascertaining what was and what is the popular idea of the medical man of the period. But who is to tell us? The novelist will. The dramatist will. The painter will. At any rate, so it has appeared to me, and I purpose to take one of each from the seventeenth century and one of each from our own day and see what they individually have to tell us about the doctor.

At the end of the seventeenth century lived Alain René Lesage. He wrote the history of "Gil Blas." In it he has drawn a caricature of the doctors of the day. Doubtless it is a caricature, but, after all, a caricature is only an exaggeration of the salient points of the individual portrayed. Sangrado is immortal. As long as there are doctors he will never die, and for all time, when anybody wants to poke malicious fun at us, Sangrado's memory will be used to poison the shaft of ridicule. You remember the description of him. "A tall, withered, wan executioner of the Sisters Three, who had done all their justice for at least these forty years. This learned forerunner of the undertaker had an aspect suited to his office:—his words were weighed to a scruple, and his jargon sounded grand in the ears of the uninitiated. His arguments were mathematical demonstrations, and his opinions had the merit of originality." There was no doubt about the last statement, for, after taking six good porringers of blood from the old licentiate Pedrillo, he says to Gil Blas: "It is a mere vulgar error that the blood is of any use in the system—the faster you draw it off the better. A patient has nothing to do but to keep himself quiet; he has no more occasion for blood than a man in a trance. Drink, my children; health consists in the pliability and moisture of the parts. Drink water by pailfuls. It is a universal dissolvent: water liquefies all the salts. Is the course of the blood a little sluggish, this grand principle sets it forward. Too rapid, its career is checked." Let me recall to you the scene where the notary is summoned to make the licentiate's will. "The notary," says Gil Blas, "was a dapper little fellow, who loved his joke, and he inquired who our physician was. At the name of Dr. Sangrado, hurrying on his cloak and hat, 'For mercy's sake,' cried he, 'let us set off with all possible speed, for this doctor despatches business so fast that our fraternity cannot keep pace with him. That fellow spoils half my jobs.'"

We really must not part from Sangrado without one more touch. After Gil Blas has been Sangrado's partner for a while he becomes dismayed at the fearful mortality which their treatment seems to produce and says: "If you will take the hint, Sir, we had better vary our system. Let us give, by way of experiment, chemical preparations to our patients. The worst they can do is to tread in the steps of our pure dilutions and our phlebotomising evacuations."

"I would willingly give it a trial," rejoined the doctor, "if it were a matter of indifference, but I have published on the practice of bleeding and the use of drenches. Would you have me cut the throat of my own fame as an author?"

"Oh, you are in the right," resumed Gil Blas; "our enemies must not gain the triumph over us. They would say that you were out of conceit with your own systems and would ruin your reputation for consistence. Perish the people! Perish even the nobility and clergy, but let us go on in the old path."

This is all exquisitely funny, but in one sense it is very terrible reading, for it is obviously so true to the life. The

English translation was made by Dr. Tobias Smollett. I wonder what he thought of Sangrado. After all, I do not suppose he considered it a very far-fetched description. Look at his own novel, "Roderick Random," written a hundred years later, and containing much of his own early experience as a surgeon's mate in the navy. Could anything be more degraded than the position of a very large section of the medical profession even at so much later a period?

Turning to the drama, it is somewhat curious to note that while Shakespeare, with the exception of the Apothecary in "Romeo and Juliet," hardly makes any allusion to medicine, Molière constantly introduces medical characters into his plays. Sad to say, they were invariably brought in for the purpose of being satirised and held up to scorn. In his celebrated plays, "Le Malade Imaginaire" and "Le Médecin malgré lui," and in the smaller pieces, "Le Médecin Volant" and "L'Amour Médecin," he is so severe upon the doctors that he almost seeks an opportunity for excusing himself. In "Le Malade Imaginaire" he makes Argan, the imaginary invalid, say:

"Your Molière, with his comedies, is a fine, impertinent fellow! I think it is like his impudence to go and bring upon the stage such worthy persons as the physicians." To which his brother Béralde replies, "He does not make fun of physicians, but of the ridiculousness of physic." Béralde is always very severe upon the medicos, and when his invalid brother says to him, "But doctors must believe in the truth of their art inasmuch as they make use of it for themselves," he retorts: "That is because there are some of them who actually share in the popular errors by which they profit, and others who profit by them without sharing in them at all. Your Dr. Purgon, for instance, does not discriminate very clearly. He is a thorough-going physician from head to foot—a man who believes in his rules more than in all the demonstrations of mathematics, and who would think it a crime to wish to examine them. He sees nothing obscure in physic, nothing dubious, nothing difficult. With an impetuosity of prejudice, a stiff-necked assurance, a coarse common sense and reasoning, he flies to bleeding and purging, and stops at nothing. You must not owe him a grudge for anything he might do to you, for he would despatch you with the most implicit faith. In killing you he would only do to you what he has done to his own wife and children, and what, if there were any need, he would do to himself."

There is a most delicious interview between the invalid and a certain Dr. Diafoirus, who is accompanied by his son, young Dr. Thomas Diafoirus.

"Argand: Pray, sir, just tell me in what condition I am.  
Dr. Diafoirus (feeling the pulse of Argand): Come, Thomas, take hold of the other arm of this gentleman, to see whether you can form a good judgment of his pulse. *Quid dicis.*

Thomas: Dico that this gentleman's pulse is the pulse of a man who is not in good health.

Dr. D.: Good.

Thom.: That it is hardish, not to say hard.

Dr. D.: Very well.

Thom.: That it acts by fits and starts.

Dr. D.: Bene.

Thom.: And even a little irregular.

Dr. D.: Optime.

Thom.: Which is the sign of intemperature in the splenic parenchyma, which means the milt.

Dr. D.: Very good.

Argand: No; Dr. Purgon says that it is my liver which is not right.

Dr. D.: Well! yes. Whoever says parenchyma says both the one and the other, on account of the close sympathy there is between them through the vas breve and the pylorus, and often through the meatus cholidici. He no doubt orders you to eat much roast meat.

Argand: No! nothing but boiled.

Dr. D.: Well! yes. Roast, boiled—the same thing. He prescribes very carefully for you, and you cannot be in better hands."

"Le Malade Imaginaire" closes with an interlude, a burlesque ceremony of admitting a doctor of medicine into the Faculty. The stage directions, after describing the hall, say: "Then the whole assembly, composed of eight syringe bearers, six apothecaries, twenty-two doctors, and the person that is to be admitted physician, eight surgeons dancing and two singing, enter and take their places, each according to his rank." There is a president, who invites members of the

assembly to "heckle" the candidate. The whole is spoken in dog Latin, with an admixture of French, Italian and Spanish that is extremely diverting, but quite untranslatable. Whatever be the question, the candidate has only one answer, "Clysterium donare, Postea seignare, Ensuita purgare," and at once the chorus bursts out into "Bene, bene, bene responderere: Dignus, dignus est intrare In nostro docto corpore." One doctor propounds a case to him with the usual answer. "But what is to be done if the case won't get well?" says the examiner. "Reseignare, repurgare et reclysterisare," cries the candidate, while the chorus roar out, "Bene, bene, bene, bene responderere." Finally, clapping the doctor's bonnet on the bachelor's head, the president gives him his licence to practise, with the right of physicising, purging, bleeding, piercing, slashing, cutting and killing throughout the whole land. "Ego, cum isto boneto Venerabili et docto, Dono tibi et concedo Virtutem et puissanciam Medicandi, Purgandi, Seignandi, Perçandi, Taillandi, Coupandi Et occidendi Impune per totam terram." The whole interlude constitutes perhaps the funniest satire on medicine that ever was written.

Now for the painters. In the house of a friend of mine hangs an old engraving by Nanteuil called "Le Bassin." It is a representation of a doctor holding in one hand an earthenware vessel containing excreta of some sort, to which he is solemnly pointing with the forefinger of the other. He wears a gown. His head is adorned with a kind of big flat cap, from beneath which flows his long hair. Round his neck is a fur collar, and large white bands hang from below his chin. His eyeglasses are somewhat awry on his nose, and he is evidently giving forth some portentous prognostication as the result of his examination. A glance shows him the incarnation of quackery. Beneath the picture are some verses in old French, the sense of which may be expressed thus:—

Doctor! this precious mess test well,

And from its savour, from its smell

Your prophecies declare

Your skill should soon procure at least

A burial service for the priest,

Whose fees you'll gaily share.<sup>1</sup>

The same form of sarcasm is seen in the famous picture, "La Femme Hydropique," and in many other productions of the Dutch and Flemish artists. It comes out at a much more recent date in the savage caricatures of Gillray. I saw one the other day in which the peasants of a village are represented shooting their rubbish. A great crowd follows three wheelbarrows in which three individuals are being wheeled away. In the first is an attenuated wretch with bag and papers—the lawyer. In the last is a great fat figure with full-bottomed wig and gouty leg done up in flannel—the parson. In the middle barrow, with three-cornered hat on head and still grasping his squirts and bottles, sits the doctor.

Now, while we have the idea of the seventeenth-century doctor fresh in our heads, let us leave two centuries behind and come to our own day. What says the modern novelist? If you want to read a charming book, go and buy *Le Docteur Rameau* by George Ohnet, one of the few French authors who do not consider it essential that the chief constituent in a novel should be literary ordure—which is considered a great crime in him by those mandarins the Parisian critics. The doctor is of the humblest origin, the son of a railway employé in the country. One day a terrible collision occurs near his father's hut. Although only fourteen, he displays such energy in helping the village surgeon, Dr. Servant, to succour the wounded that the latter sees his genius. He gets him put to school, and, in due time, with the aid of scholarships, gained by his indomitable hard work, Rameau has his choice of going to the *École Polytechnique* or to the *École Normale*. Here his benefactor, Servant, steps in and says to him, "Do thou be a doctor. What I have given to thee give back to thy fellow beings. That genius, which is undeniable in thee, place it at the service of humanity." When he comes on the scene Rameau has reached the highest grade in his profession. He is a professor and operator of renown, in great request as a consultant and a famous clinical teacher. Here is the description of him: "Fifty years of age, with a vigorous constitution never weakened by any excesses, Rameau is a man of great stature, with a visage rugged as a volcanic soil. His big forehead

<sup>1</sup> De ce mets précieux goûte, friand Docteur,  
De son odeur, de sa saveur  
Tire d'Infaillibles presages.  
Voi si ton Art aura promptement procuré  
Des De Profundis de curé  
Avec qui gaiement tu partages.

is crowned with grey hair, wavy and coarse, like the mane of an old lion. His grey eyes, clear and piercing as his own steel instruments, are surmounted by eyebrows, black and shaggy: A ruddy complexion tells of blood boiling with the activity of a life absolutely devoted to toil, and his thick-lipped mouth breathes of kindness. But there is a deep wrinkle at the root of the nose, furrowed between the eyebrows, and when he is profoundly occupied or when he is annoyed this wrinkle gives him a fearsome look. At the hospital or in the amphitheatre, when the word is passed that 'Rameau has got his wrinkle,' it is a storm signal for the house surgeons and pupils. Not a man but trembles and holds his peace when that fearful furrow comes over the usually genial brow of the *savant*, for his bursts of passion are formidable and nothing can stop them. His roughness is as well known as his skill. No woman ever put on a dressing or adjusted a bandage with a lighter hand or more dexterous fingers; no carter ever swore at his horses more furiously than the doctor at his assistants. The frightened patients get under the bedclothes or bury their heads in the pillows when they hear the thundering voice of the surgeon as he flourishes with a menacing air some sharp-bladed instrument. He does what has to be done for them; and then, transported with joy, the poor things, more dead than alive, learn that the operation, which they fear has hardly begun, is already over and finished. Then it is that they bless the skill of that kindly carver and come to know why it is that the house surgeons and pupils laughingly say behind his back, 'It's only Rameau's tongue that ever hurts his patients.' Without doubt, the confidence which he inspires accounts for half the success of his treatment. It is so well established that the presence of Rameau by the bedside of a sick man puts death to rout that at the first glimpse of the doctor as he comes in the patient feels himself saved. No great person in the land ever has a serious illness without Rameau being summoned at whatever cost. When the Innspruck surgeons wanted to cut off the Archduke Charles's leg, after he had fallen into a ravine chasing the blackcock, it was owing to his skill and ingenuity that the prince was saved from being a lifelong invalid. For his trouble he demanded a hundred thousand thalers. He once went to operate on Garibaldi for a phlegmon, which was seriously endangering his life. He asked from the grand old adventurer, as a fee, a flower from his garden. Rameau is a democrat and a freethinker—a democrat because, sprung from the people, he has inherited their bitter notions about equality; a freethinker because in his profound scientific researches he has only encountered at the end of his scalpel mere matter, and because his powerful mind refuses to admit what it cannot explain."

Is not this a delightful description of a modern French doctor by a modern French novelist? I think you will forgive me quoting for you a charming incident. There are two ladies, widowed mother and daughter, who have been reduced from affluence to poverty and barely eke out an existence by dressmaking. Their old servant Rosalie still clings to them. The mother takes ill and is at the point of death, and the daughter's anguish is terrible. Then the servant Rosalie invades the crowded consulting-room of Rameau. She is arguing with the manservant, who is telling her that the doctor cannot possibly see her till the following day. Then comes this scene—

"The sound of a bell interrupted the talk and, without giving a thought to the distressed woman, the manservant opened a door and proceeded to let out the person who was leaving the consulting-room. In the half light of the waning day the tall figure of Rameau appeared. Some brief parting words were exchanged between the doctor and his patient. The woman, who was weeping, had raised her head. With the intuition of grief she divined in that unknown, barely visible person the saviour she had come to implore, and, rising sharply, she precipitated herself after him into the room. Rameau did not hinder her, but looked her all over with a smile.

"What is it, my good woman?' he said, in his deep, grave tones.

"Oh! my dear sir! Surely you are Dr. Rameau; are you not?"

"Yes, I am."

"Then it must be Providence that has permitted me to reach you. Ah! Great Heaven! your servant was just telling me that I must either wait or come back to-morrow. As if death would wait!"

"Death!"

"Yes, my dear, good sir, our doctor has said so. It is a question of hours. If the operation is not done this very evening my mistress will never get over the night. And we heard that it was only you that could save her. Then mademoiselle said to me: 'Run for Dr. Rameau and bring him. Ah! Dieu! promise him what you like; we shall sell the furniture, if necessary, to pay. Only let him save mother!'"

"Rameau knit his brows. The woman saw a cloud pass over the face of the *savant*. She reddened and stopped, quite confused.

"Forgive me,' she cried, 'I am so troubled that I say anything that comes first; but I am indeed sorry to have offended you.'

"Rameau made a careless gesture.

"Are your mistresses, then, poor?' he asked.

"Alas! Yes! The dear ladies! After having been in such an excellent position too, distress is all the more painful for them. But so good, one would be cut in pieces for them. And mademoiselle, so sweet and so beautiful. Ah! doctor! if you only knew her!"

"Well, now, what's the matter with your invalid?"

"Oh! some sort of gangrene. At first they treated her for rheumatism in the shoulder, and then, day after day, they have seen her steadily going from bad to worse. Ah! Sir! if she had been rich, as she once was, they wouldn't have let her go to the last gasp. But the poor! They can die. Isn't that so?"

"Rameau threw back his head and very gently replied, 'No, my good woman.'

"Then he calls his carriage and goes out with her, leaving the rich occupants of the crowded ante-chamber to come next day. He cures the mother and marries the beautiful m'amselle. After some years his wife dies, leaving him a daughter, and terrible griefs and calamities accumulate around him. Still he obstinately remains a disbeliever and an atheist, and under the burden of his sore troubles he only becomes more and more defiant and obdurate. His miseries culminate in what threatens to be the fatal illness of the beloved child. But she recovers and marries her father's assistant, and the story closes with a beautiful scene in the church at the marriage. Beside Rameau sits his old and faithful friend Talvanne, who has stood by him through all his troubles.

"At that moment, with measured steps, the priest descended from the altar to unite the young couple. Adrienne's uplifted veil allowed her countenance to be seen bent down in fervent prayer. At the question, 'Do you take for your husband so and so?' she answered with a clear tone, 'Yes;' and her gaze, turned a little sideways, riveted itself on her father as if to offer to him all that happiness which filled her. That look expressed a tenderness so profound that it penetrated Rameau to the heart. At the same instant the sun streaming through the windows of the choir kissed with its rays Adrienne's yellow hair and lit it up as with a golden glory. So she appeared as if transfigured, almost isolated in a divine luminosity, like some young saint come down among men. In her Rameau beheld an angel sent to him to console him for all his miseries. All that remained in him of bitterness or pain melted away in a delicious ecstasy and, full of humble gratitude, he knelt down. Talvanne, hearing him speak in a low tone, leaned over to listen and heard these words murmured with fervour, 'My God! My God!' It was the atheist who was praying."

And now, how do they put the doctor on the stage nowadays? The other night I went to the theatre to find out. I went to see Sydney Grundy's play, the "Fool's Paradise," in which the chief part, that of Sir Peter Lund, the physician, is played by my old friend, Mr. John Hare. In a character of this sort Mr. Hare has admittedly no rival in this country, and therefore it need hardly be said that the part was played to perfection. Doubtless many of you have seen the play, and will remember the admirable make-up of the old doctor, who obstinately keeps up, even in his dress, the traditions of his youth. He is brusque and dictatorial, but there is a total absence of solemn pretentiousness about him. He affects not to know anything, and would have you believe him to be a sort of medical agnostic. He actually delights in making fun of his own profession. But he has not uttered half a dozen sentences before you see that he is a shrewd man of the world, who has mixed with every class of society, from the peer to the pauper. He knows that drugging is for the most part useless, and says so; only the public will have drugs and do not believe in a doctor who talks common

sense to them. There are some capital bits of humour in the conversations between Sir Peter and his patient Philip, whose mysterious case he is quietly and accurately fathoming, while affecting all the while to talk nonsense to him. Sir Peter says to him—

“Well! what’s the matter with you?”

*Phil.*: Really, Sir Peter, that’s what I want you to tell me.

*Sir P.*: You have a high opinion of the medical profession. Do you suppose we can tell you anything if you don’t tell it us first?

*Phil.*: I have always supposed so.

*Sir P.*: Error, sir. You tell us everything we tell you. The only difference is you tell us in English and we tell you in Latin. You take a fee out of your pocket; we put it in ours.

\* \* \* \* \*

*Phil.*: You are plain-spoken, Sir Peter. Now, tell me with equal candour what is the matter with me.

*Sir P.*: Shall I tell you the truth?

*Phil.*: Of course.

*Sir P.*: I don’t know.

*Phil.*: Surely with your experience—

*Sir P.*: Sir, I have no experience.

*Phil.*: Well, with your knowledge—

*Sir P.*: Sir, I have no knowledge. Knowledge is the monopoly of extremely young practitioners. I have been doctoring for forty years, and now I stand here on your hearthrug, sir, a monument of triumphant ignorance.

*Phil.*: Nonsense, Sir Peter.

*Sir P.*: Sense, sir, sense.

*Phil.*: Be candid and tell me frankly what is wrong with me.

*Sir P.*: Your liver, probably.

*Phil.*: Only my liver!

*Sir P.*: Don’t speak disparagingly of your liver, sir. That eminently respectable organ has been much misunderstood. It is commonly supposed to serve certain functional purposes in the physical economy. Another fallacy! The liver was made by a beautiful provision of nature for the benefit of the medical profession.”

During the play I watched the audience to see what they thought of Sir Peter. They evidently liked him very much. They enjoyed him. In one scene the wicked wife, who does not wish him to prolong his stay in the house, says to him: “But what will your patients do without you, Sir Peter?” “Recover,” he answers, and bolts out of the room. This amused them amazingly. But why did they like him? I am certain they liked him for his honesty and his kind-heartedness. In spite of his odd ways and affected cynicism one could see that he was a genuine, true friend, and, in his own heart, was oppressed with anxiety for the safety of his friend and patient. And when the time came for a terrible disclosure and he had to denounce the miserable wife as the poisoner of her husband he rose to the occasion. There was no affected cynicism in the sharp clear voice with which he said, “I suspected you from the beginning.” He stood out a courageous old man, prepared to do and say anything for the right.

Finally, we come to the painter of to-day. It will not be denied that the picture of 1891, the one which stood out clearly and prominently above all the other pictures of the year, was Mr. Luke Fildes’ “Doctor.” Of the hundreds of medical men who must have stood before that picture I am sure there was not one whose pulses it did not quicken with pleasurable pride, or who left it without thinking that it already had been, and again would be, his privilege to fight against pain and suffering and death like his colleague on the canvas. For to us he is a real living man like ourselves. We have acted like him and felt like him.

Note where the scene of the picture is laid—not in some rich man’s mansion, where the doctor might reasonably expect a handsome fee for his trouble, but in a working man’s cottage, where most likely the gratitude of the people and a consciousness of having done his duty by the poor would be his sole honorarium. With admirable skill the painter has pitched on the early hour of morning for the time. The light of the lamp in the room and the light of the dawn coming through the casement are struggling with each other. It is the cold sad hour when human vitality is the lowest and when statistics tell us most men die. The sick child, worn with the raging fever that commonly burns from eight in the evening till one or two in the morning, lies spent and exhausted. Till then the parents have been fighting on with their nursing; soothing, caressing, en-

couraging their little one. But now they too are exhausted and depressed, and hoping against hope seems all that is left to them. And there sits their friend—the gentle doctor—watching with them, and still puzzling his brains to think what more he can devise to stay the lamp of life from flickering out. He is no courtly physician. He is only a country doctor, but his somewhat rugged face tells of honesty and common sense and self-reliance and gentleness. What more do you want? The men that look like that man, whatever be their business or trade or profession, whatever be their wealth or their social position, I say, of such men is the kingdom of heaven.

Let us, then, take a review of the whole matter. This much is clear, that when a personification of the doctor was presented to the public two hundred years ago, he was invariably held up to ridicule as a quack. He was a man who pretended to a knowledge that he did not possess—by consequence a man whose life was one continual fraud. His language was inflated and bombastical, and his sesquipedalian words were employed to distract attention from the unintelligible and idiotic ideas which they concealed. Having a love for collecting old medical books I have dipped a good deal into them. Often, after coming to the bottom of a page, I have read it again, and if it had been written by any lunatic in Bedlam it could not have been more absurd or vacuous. The word “experiment” was almost unknown. If there arose a question as to whether some particular thing was blue or red, men did not go to find it, and see with their own eyes whether it was blue or red, but they sat in their closets and argued about it. I must admit that if the doctors of that day were always presented to the public as quacks they did their best to deserve it. The next thing that is clear is that they were overbearing, greedy, hard-hearted quacks. Never once are we shown one of them doing a good or kind action. The doctor is an impostor whose sole object is to get his fee. That fee he must have if the wretched patient has to sell the shirt off his back for it. Such, I assert, is the impression which must be conveyed to the mind of anybody who reads the novels or dramas or looks at the pictures or caricatures of the seventeenth century. But were all those old doctors like this? No, most certainly not. There were splendid men among them. Look at the names of Morgagni and Bartholin and Willis and Sydenham and Malpighi, among many others. These men had as great patience, as keen wits, as unselfish motives and probably more courageous hearts than any of our scientific men of to-day. Their labours and discoveries were as great and as important as our own. We are every day making use of their work, just as the twentieth-century doctors will make use of ours. But they were in a small minority. Their bright and glorious example had not descended. The rank and file of the profession were still the greedy quacks that Le Sage and Molière and the Dutch artists painted. Molière has been accused of having been too severe upon the doctors of his day, but no ridicule can be too severe when it is employed to expose the humbug and the charlatan. To him, as a profession, we are under an eternal debt of gratitude. As a body we were sick men. His physic was bitter enough in all conscience, but it took hold of the disease and cleansed away many of our impurities.

Turn we now to the picture of to-day. Whatever be the shortcomings and weaknesses which the doctor has, in common with all his fellow men, they are not now seized upon and savagely caricatured and grotesqued to amuse a jaded public. Nobody makes more fun of us than *Punch*. But his fun is always so genial and good humoured that, when a medico forms the principal figure in one of his pictures, the medicos eagerly buy the paper to enjoy the joke. And when a doctor has done some self-sacrificing bit of heroism, who so ready to sing his praises as our dear old friend *Punch*? If you go to the theatre you will see that the people like Sir Peter Lund. His *brusquerie*, his pretended cynicism, and his real tender-heartedness please them. They admire his honesty and his fearlessness when the moment for decisive action arrives, and they are amused with the keenness and shrewdness which a long acquaintance with men and things has given him.

And, finally, tell me a picture that has ever appealed more powerfully to the public than Mr. Fildes’ great work? Naturally it has had to run the gauntlet of severe criticism; but to attract criticism is in itself a sign of the inherent value of a thing. As to the technical merits of the picture I say nothing. Artists are the proper judges of that. But when they accuse the painter of false sentiment I join issue with them at once. To my mind a picture is falsely sentimental

when the artist represents in it a scene or situation which does not occur and is consequently unreal, with the object of eliciting our sympathy and our more tender emotions. But the situation represented in "The Doctor" is not an unreal one. It is a painfully common and real one. It is one which occurs continually in our lives. Would that I had some Asmodeus to lift off the roofs of the houses of Great Britain to-night and to take these critics to where life and death are engaged in the final contest for the mastery. They would see to-night—this very night—Luke Fildes' doctor sitting by the bedside watching for every deeper breath, every stronger pulse that might give him hope to go on with the fight. They would see the country doctor in the Highland cottage or the Yorkshire farmhouse. They would see the physician of renown in some great nobleman's palace. They would see the house surgeon in the hospital ward. But, in whatever capacity he might be revealed, of this I am sure, that he would be seen overmastered by the one idea of how to save his patient and how to show himself the gentle comforter of the afflicted friends. I have just said that we owe much to Molière for lashing out of us the quackery and ignorance that prevailed in his day. But what do we not owe to Mr. Fildes for showing to the world the typical doctor, as we would all like him to be shown—an honest man and a gentle man, doing his best to relieve suffering? A library of books written in our honour would not do what this picture has done and will do for the medical profession in making the hearts of our fellow men warm to us with confidence and affection.

And now, my dear young friends, we are nearing the end of the nineteenth and you will be the doctors of the twentieth century. Upon you will devolve the responsibility of maintaining that honourable position in the sight of all men which your forefathers have struggled to win for the profession of their choice. You are no longer students of a mere provincial school of medicine. You are members of a college of a university, which, before your days are ended, will have revolutionised education in the north of England. The ground has been prepared and planted and watered, and you are the first fruits. Yours it is to bring forth an abundant harvest of good works, not merely for the credit of your profession, but for the glory of your *alma mater*. You must copy the intense industry, the resolute will, the single-eyed devotion to science of Docteur Rameau. You must, like Sir Peter Lund, learn to be wise as serpents as well as gentle as doves, so that you may bring to bear upon your patients' cases not merely a knowledge of morbid anatomy and drugs, but also a knowledge of the ways of the world and of the inner workings of men's lives. But, above everything, whatever may be the rank in your profession to which you may attain, remember always to hold before you the ideal figure of Luke Fildes' picture, and be at once gentle men and gentle doctors.

I take my farewell of you in the words with which Molière's president opens the examination function for the Bachelor of Medicine—

Savantissimi Doctores,  
Medicinae Professores,  
Qui hic assembleati estis;  
Et vos, atri messores,  
Sententiarum Facultatis  
Fideles excoecutores,  
Chirurgiarum et apothecarum,  
Atque tota compania aucti,  
Salus, honor et argentum  
Atque bonum appetitum.

**LOWESTOFT HOSPITAL.**—The committee of this hospital, in their report, state that there has been an increase of expenditure during the past year, due to the increased stress put upon the hospital by the terrible accident at Barnby in December last. Increased accommodation is required, and accordingly plans have been prepared for new buildings, the cost of which is estimated at £900. Sir Savile B. Crossley, Bart., has been elected president of this hospital in place of Mr. W. F. Larkins.

**A DILEMMA AT POPLAR.**—The district of Bow, Bromley and Poplar has two medical officers of health for the three parishes, Mr. Corner and Mr. Talbot. The former has resigned with a gratuity of £390, and the Board wish to place the whole of the district under one medical officer; but Mr. Talbot is not, of course, compelled to resign or take sole charge and thus the Board is in a difficulty. The sanitary committee, as a compromise, recommend the appointment of a new medical officer for Bromley and Poplar.

OF

### INTRODUCTORY LECTURES ETC.

DELIVERED AT THE

LONDON AND PROVINCIAL MEDICAL  
SCHOOLS

AT THE

Opening of the Session 1892-93.

ST. GEORGE'S HOSPITAL.

INTRODUCTORY ADDRESS BY DR. R. L. BOWLES.

THE address opened with a welcome to the new students, and with some references to the great services rendered by St. George's Hospital and its medical school in the past, and to the great and peculiar advantages enjoyed by the present generation of students. They were asked to have confidence in and to cultivate the friendship of their teachers, and to preserve the tradition that "a St. George's man is expected at all times and under all circumstances to be a gentleman." The apprenticeship system was announced to be dead, defeated by the rapid march of science. This led to the main subject of the address, "the application of physics to physic." The lecturer then pointed out that all changes occurring in physiological and pathological processes, formerly supposed to depend on that unknown quantity "vital force," were really nothing more than the action of the recognised forces of nature on the organs and structures of the body. Reference was then made to his own researches on the influence of physics in the treatment of the apparently drowned, and to their influence on patients suffering from apoplexy, chloroform poisoning, and all states of unconsciousness. Coughing, sneezing, snoring &c. were all shown to have immediate origin in physical conditions. The lecturer went on to say that almost all the work of surgery is done by the proper application of the laws of physics; injured parts and broken limbs are kept at rest, dislocated parts are placed in their natural positions, redundancies are removed, and natural deficiencies often well supplied; crooked paths are made straight, and blocked and narrowed ones made patent; stiffened joints are made to move, crooked limbs put into shape; eyes are made to see that would not, and ears to hear that could not. Surgery is a department of physics; a physical art. Medicine, formerly the region of the unknown and the happy hunting ground of quacks, is rapidly following in the same lines. The so-called practical man and the believer in dogmas and nostrums are rapidly giving way to minds trained in the laws of physics. Physiology, medicine's forerunner and its handmaid, is steadily step by step, and without prejudice, elucidating the ways and doings of animal life. By instruments of the most elaborate and delicate nature, by patient and continuous observation, by anatomical and histological searchings, and by the application of the laws of gravitation, chemistry, heat, light and electricity, always by ways and means connected with physics, we are getting to understand better and more surely the movements and functions of respiration, of circulation, and digestion, of secretion and excretion, and finally we hope to understand the most subtle and mysterious of all functions, the operation of the nervous system. Physic, or the sphere of the physician, is the application to diseased or disordered conditions of the ways and means of physiology. We reduce to experiment the disordered state that we may learn its real nature and be enabled to bring it back to order by the use of natural and appropriate means. Students were advised of the necessity of acquiring sound principles and exactness in the sciences; the lecturer mentioning the difficulties which beset him in his earlier years from not starting well equipped in this respect. The value of experiment was next commented on. Sir John Simon had said: "The experiments which give us our teaching with regard to the causes of disease are of two sorts: on the one hand we have the carefully pre-arranged and comparatively few experiments which are done by us in our pathological laboratories, and for the most part on other animals than man; on

the other hand, we have the experiments which accident does for us, and above all the incalculably large amount of crude experiment which is popularly done by man on man under our present ordinary conditions of social life, and which gives us its results for our interpretation." This was illustrated in the case of cholera: on the one hand were Professor Thiersch's scientific infection experiments performed on mice; on the other the experiments in connexion with water-supply, in the 1848 and 1853 epidemics, performed on half a million of people in South London. Both gave the same result. "The experiments which illustrated the dangerousness of sewage-polluted water-supplies cost many thousands of human lives; the scientific experiments which, with infinitely more exactitude justified a presumption of dangerousness, cost the lives of fourteen mice." Passing on to the bases of all true medical work, anatomy, physiology and pathology, he said that anatomy contemplates the parts of the body in a state of rest, the structures on which functions play. Physiology contemplates the parts of the body as living and in process of change, change not only of a mechanical kind, but change of energy and of form, which are the necessary results of function. Pathology is but a part of physiology, the one declaring what is normal in function, the other what is more or less a departure from the normal. Hippocrates more than 2000 years ago proclaimed pathology to be a branch of the science of nature; the slowness of its development can only be explained by the equal slowness of the progress of the natural sciences themselves. Of late years, however, advances have been truly made by leaps and bounds. Professor Schroeder in Germany and M. Pasteur in France, by their investigations on fermentation and putrefaction, and M. Chauveau on the particulate nature of contagia, opened up an entirely new world to us all. We have now not only to study the causes as well as the changes of the disease in the body, but also the doings of the bacteria outside the body and within it. These facts applied to the State at large, forming what is called State medicine, have increased the average duration of life and diminished the suffering consequent on bad health and disease. Each succeeding year shows more and more clearly the great value of physics in the department of preventive medicine. Sir John Simon years ago showed the important part which medicine played in the political economy of the country, and he succeeded in due time in bringing the State and the medical profession into organised relation with one another. Next was pointed out the manner in which physics may be applied for remedial purposes. Change, muscular and nervous, lies at the root of all recreation. The students were reminded that "all work and no play makes Jack a dull boy," and that games and the pleasures of exercise may well be enjoyed during their pursuit after knowledge. Extremes should be avoided, and when really tired rest was a necessity, for fatigue implies diminution of the physico-chemical changes connected with the evolution of force. In some states, movement, exercise and massage may be useful; in others, air, fresh air, or change of air, more of nature's medicines, as are also heat, electricity and light; the last of these having been experimentally shown by the lecturer to produce some very singular effects in connexion with sunburn. Lastly, the lecturer said that we come to the consideration of the administration of medicines. Here empiricism has hitherto been almost supreme, but, thanks to the sciences, clearer and more certain views are taking its place. *Materia medica* or the knowledge of the remedies employed in medicine has its divisions, its departments, each and all being worked on scientific principles. Pharmacology is the knowledge of the mode of the action of drugs upon the body generally and upon its various parts. Therapeutics imply the administration of remedies suitable for the relief of particular symptoms in proper doses and proportions. Long and complicated prescriptions are to be avoided. Not a single drug ought to enter the body except under clear intention of what object it is to fulfil there. Compounds may be good cookery, but do not form scientific medicine. We cannot by any amount of training make a man distinguish himself in a subject to which he is by nature unfitted. Like a real artist the man must have "the touch of the finger of God, of the all-informing, all-creating imagination."

"There's a divinity that shapes our ends,  
Rough-hew them how we will."

In conclusion, Dr. Bowles warned the students against mistaken views of materialism. The "*ars medendi*" is practically illimitable. In Bacon's use of the term, it is coexten-

sive with the whole field of terrestrial nature and the students of the physical and biological sciences are emphatically the servants of nature. Sir Thomas Browne, in his "*Religio Medici*," tells us that "nature is the art of God." Do not ever be bewildered into supposing that there is any antagonism between religion and science; there is no such antagonism. The man of science interprets the physical laws, and equally with the teacher of religion tells us of the greatness and grandeur of the Creator. Every discovery of the scientist can only tend to increase our wonder at the omniscience and perfection of the ways of God.

#### GUY'S HOSPITAL.

##### INTRODUCTORY ADDRESS BY MR. A. ERNEST MAYLARD.

MR. MAYLARD, after expressing his appreciation of the honour which he felt had been conferred upon him in asking him to come from Glasgow to deliver the opening address, proceeded in the course of his remarks to speak of the value of cultivating a spirit of inquiry. He said he considered it one of the best attributes possessed by a student and one of the best faculties to maintain throughout life. "We needed nowadays, more perhaps than at any previous period, to cultivate an attitude of mind which was ever seeking to know the truth. Our profession was one which was peculiarly handicapped in the matter of advance. It was so easy to promulgate a principle or theory, but so difficult to be certain that its basis was sound. It was true enough that we spoke of the science of medicine and surgery, and yet we could not speak of the science of human nature. It was too variable in its formation and function to admit of the framing of general laws. Hence true advance was often hindered by the innumerable practices founded on some false theory or inculcated on insufficient grounds. One, perhaps, of the commonest errors to which we were addicted was that of generalising from a too limited field of experience, assuming, for instance, that what proved suitable or successful in one or two individual cases would effect a like result in all others. Again, we were often apt to forget that within the greater part, if not within the whole period of its existence, the human body had a constant inherent tendency to return to a certain normal standard, and we were apt to assume that measures adopted by us effected results which in reality were due to nature's own work. How should we then as inquiring students contend with these difficulties; or what should be our attitude in respect to them? If we constantly cultivated and exercised a spirit of searching inquiry we should, in the first place, ourselves not be ready to make assertions which we honestly felt had not yet stood the test of a sufficiently extended experience; and in the second we should not be over hasty in adopting every nostrum that is put under our nose, every treatment we read about, without being first fully satisfied as to the veracity of the statements made or the merits of the claims advanced." To illustrate more fully and graphically how a student should exercise and cultivate his faculty of inquiry, Mr. Maylard proceeded to picture in imagination a case of a wound dressed antiseptically. The practical treatment of such a case was carried out with the most elaborate details, formed on a very simple principle. The questions which the inquiring student would ask were whether every detail of the procedure was an accurate fulfilment of the conditions required by the principle, did every agent employed effect the result desired? It was pointed out that in view of the rapid development of the science of bacteriology many new theories and practices based upon them were and would be sent forth into the medical world. But every inquiring student should be cautious in not accepting too hastily conclusions which a more careful and prolonged consideration may prove after all to be based on some false or mistaken theory. In conclusion, Mr. Maylard said: "If the faculty of inquiry was to be exercised to its fullest advantage in our professional life, it must be cultivated to an equal extent in all our relations to the world around us. It should form as much a part of our religion and our politics as our profession. It was hardly possible to think of a man as a bigoted sectarian, a purely party politician or a rampant advocate of any sect or subject, whose mind had been broadened and his views extended, by a searching inquiry into the subject at issue. Dogmatism in any shape or form was not an attribute that belonged to the followers of our profession. It indicated a limited, not an extensive, knowledge. It is for us ever to be seeking and making each truth as it is found, not the limit of our inquiry but the basis for the discovery of another."

## THE MIDDLESEX HOSPITAL.

INTRODUCTORY ADDRESS BY DR. SIDNEY COUPLAND.

"My first words must be ones of regret and apology—regret which we all feel that Dr. Pringle, to whose address we had been looking forward, should have been ultimately compelled by indisposition, arising, I fear, from too unremitting devotion to duty, to abandon the task we had imposed on him. He has been reluctantly compelled to deprive us of an anticipated pleasure, and that has necessitated my appearance before you in an unexpected character. I am very grateful to my worthy colleague, Dr. Pastour, for relieving me of my official duties on this occasion, but I owe my hearers an apology for having rashly undertaken to play the part of understudy to the chief actor of the day. We felt, however, that to have omitted this portion of the programme altogether would have been hardly courteous or right. I trust, then, that I may have your indulgence while I endeavour to maintain this time-honoured institution. The main object, I opine, for these introductory addresses at the opening of our winter session is to welcome those who sit on these benches for the first time, to hold out to them the hand of fellowship and to bid them Godspeed in their new career. To such, then, on behalf of my colleagues and all members of this school, I offer this cordial greeting, promising that although you may find the pursuit of medical studies somewhat arduous and exacting, yet that it is full of those pleasures which are well known to accompany the exploration of new regions, and that day by day, as Nature yields up her secrets, you will find them more and more fascinating. If it were not for those examinations which loom so fearfully in the distance your career here might be almost romantic as you explore the unknown; but we are forced to realise the stern utility of our labour and think to what purpose we shall be required to put the knowledge we are gaining. I have only this to say, that he who does pursue his work in the spirit of the scientific investigator will be sure to have made his knowledge so accurate that he will have no fear of any board of examiners. Therefore, the chief advice I would give you is so to work practically and personally at all your subjects as to fully master them and never stop to inquire whether it might be better to omit some matters and to dwell long on others because they may or may not be likely topics to find favour in the examiner's eyes. You are fortunate in the time of your entrance upon this calling. For in no period of the world's history has there been such a keen desire to find out the truth of things. The sciences which at the opening of this century were emerging from obscurity are now daily enriching the world with their benefits. Never indeed were the advances of knowledge so rapid and so fruitful. We see this not merely in the multiplicity of inventions, all tending to conduce to the material comfort and happiness of mankind, but notably also in medical science, where the labours of numberless investigators in tracking diseases to their sources are leading us to more rational measures for their prevention and treatment. If the golden age ever does arrive when preventive measures will have made scarlet fever, typhoid fever, diphtheria and tuberculosis as rare in this country as typhus fever, relapsing fever, the plague and leprosy, and to a certain extent all manner of surgical septic diseases, there will still remain much for medicine to do in its task of rendering the earth fit to live in. Only quite recently we have been forcibly reminded of our ignorance and impotence. For, as if to mock our science and our skill, the world has witnessed during the past three years the recurrence of a pandemic disorder which has periodically traversed the globe in historical times—a malady which, though often apparently trivial in its immediate symptoms, has indirectly been responsible for an untold amount of sickness and mortality." Turning to the older branch of the medical art—that of healing—the lecturer asked: "Is the advance also great upon that line, and how is it being pursued? It seems a truism to say that the more we know about diseases the better we shall be able to treat them. Still, although we have learned much respecting the art of healing, we have infinitely more to learn and much, I think, to unlearn. The sarcasm which Molière levelled at the physicians of his day is not without meaning now. We too may often err in assigning too great importance to remedial measures and too little to the beneficent working of the organism itself. No one has more emphatically urged this than the late Dr. H. G. Sutton of the London Hospital, who combined in one the gifts of the practical physician, the philosopher and the poet. His lectures should be read by every member of our profession as an antidote against the common error of mistaking recovery for cure.

It has been sometimes urged as a reproach to physic that in respect to the treatment of disease her advance has been far behind that of surgery. I am not about to make invidious comparisons or to meet this criticism with the rejoinder that the opportunities for the performance of the new surgery have been largely owing to a sounder knowledge of the facts of pathology and a greater perfection in diagnosis." After alluding to the benefits conferred by this increased surgical boldness, the lecturer continued: "That there is also progress in the domain of medical therapeutics it would be idle to deny, but unfortunately in this department we are still largely under the influence of teachings framed in times when the structure and functions of the body were imperfectly known, and the operations of disease hardly understood at all. And, moreover, it is because of the darkness which still prevails concerning the intimate processes of disease that we still have to grope our way and trust to the haphazard inferences of experience in many of our prescriptions. I am far from wishing to minimise the importance of those studies in *materia medica* to which you will have to devote many hours; they have their place, not only as a mental exercise, but as a source of information upon what was once the chief armamentarium of the doctor which it would be a pity to lose. Nevertheless at the risk of being pronounced a heretic by the College to which I have the honour to belong I make bold to say that the place taken by drugs in the treatment of diseases is very often a purely subsidiary one. In saying this I must guard myself from misconception. There are many occasions where the prescription of appropriate remedies is of inestimable service, but very often this part of treatment is necessarily unscientific—that is, empirical or irrational. The difficulty lies in affirming in many cases what is the precise nature of the change introduced into the economy by the administration of physic. And this difficulty is enhanced by the fact that we deal with patients, living individual organisms, and not with abstract morbid states. That much-abused genius Paracelsus was far in advance of his contemporaries of the dark age of medicine when he declared that drugs acted on the body by virtue of chemical changes; and the lacuna that has still to be filled is to determine what is the precise change that is necessary to be effected in any given case. Of one thing at least we may be thankful, and that is that the days of polypharmacy are numbered; but, as a set-off to this, we seem to be living in times when a new remedy is vaunted every week, and after a brief but glorious existence sinks into oblivion. I tremble to think of the labours you would have to undergo were it not for the limitations imposed by the British Pharmacopœia and the Schedule of Drugs which the Examining Board has considerably drawn up as being all that is really necessary for you to know. I suppose that the old conception of the apothecary as one whose skill was bound up with the multiplicity of the remedies he might have for every ill is still prevalent, for we have ample testimony of the popular belief in the virtues of physic daily before our eyes. Few things are more surprising, and indeed more saddening, than to find in these enlightened days when the schoolmaster is abroad in all parts of the land that one of the most certain ways to a great fortune is to be the inventor of a pill or a mixture, or even of an ointment. Nay, you have only to shut yourself up in a remote castle and turn out bottles of electrified distilled water to be praised and even worshipped as a saviour of society by the learned and noble. How deeply ingrained must have been the old faith in medical magic for it to have survived so many centuries and to have thriven even amongst those who have been subject to all the culture of the nineteenth century! In this blind, unreasoning faith in panaceas—the very antithesis of the scientific spirit—we have a striking object lesson, not of the virtues of medicine, but of its weakness, of the triumph of credulity over knowledge, and in the effects of such misnamed "remedies"—of the influence of the mind over the body. It is possible, too, that even we who may wish to deal with diseases in an intelligent manner have inherited traditions and prejudices as regards healing which we are unable or unwilling to cast aside, although we cannot help feeling how little we often really know of the action of drugs in individual cases. This demands a thorough investigation of each case, and an appreciation of the conditions of life and environment which may influence the individual organism, including the tendencies to special forms of disease that may be present in the patient's family. The old practitioner who is familiar with the constitution of his patients and their children is mostly a far better guide than the consultant whose acquaintance with them is probably of not

more than ten or fifteen minutes' duration. I should have liked to trace out in more detail the directions in which it seems to me the medicine of the future will mainly tend; but under the special circumstances of this occasion I forbear to tax your patience or my powers in the pursuit of what after all would be mere fanciful speculations. I therefore hasten to turn to a more prosaic, but to all of us a more immediately pressing, question, that of medical education in general and in this city in particular. The aim of our profession being, as I have indicated, of a twofold nature—namely, to prevent disease on the one hand and to assist the natural powers of recuperation in the deranged or injured organism on the other—it is plain that the basis of all our study must be founded on a thorough knowledge of the laws and conditions of life and of the structure and functions of the body. Starting from this foundation, the next superstructure in the edifice of our art is that of pathology, the sum of all the ascertained facts concerning the mechanism by which diseases are brought about and the effects they produce on the organism. In its fullest sense, then, pathology embraces not only the changes to be ascertained by dissection and microscopic and chemical analysis of the dead body, but also the perversion of the natural vital processes and even the causes or conditions antecedent to the departure from a state of health. It is not for me here and now to criticise the scheme of study which in conformity with the revised regulations of the Conjoint Board we have adopted here. In very many respects it is a decided benefit to the student, who will find that even five years is all too brief to enable him to assimilate all the subjects that are now demanded from him. But I cannot avoid expressing my own conviction that the next step in the improvement of the curriculum must be the relegation to a period antecedent to the strictly medical course of the purely scientific subjects—physics, chemistry and biology. The great merit of the new scheme of study is undoubtedly the prominence it gives to practical work. In almost every one of the branches there are now classes and arrangements to enable each student to find out for himself most of the facts about which he reads in his book or learns from the lips of the lecturer. Time was when this kind of work—the most attractive and the most fruitful—was limited to only one or two subjects. But we live under a new régime, and if only it be faithfully carried out it should prove of great advantage. By faithfully sticking to his practical work, whether in the wards, the post-mortem room, the laboratory, or the dissecting-room, his memory will be strengthened, since the avenues to it through the senses will all have been opened up. Then when the examination day comes round the diligent dissector will have his anatomical facts almost literally at his fingers' ends, the patient histologist will see in his mind's eye what he has perceived through the microscope, and the clinical worker will recall the physical signs of the cases he has observed far more readily than he will remember the descriptions which he has merely read. It is surely well in these days, when there is a plethora of text-books and an almost inordinate amount of oral tuition, to remember that the only knowledge which is really *one's own*, that which is of the only real service in practical life, is the knowledge founded on personal observation, upon which we were told of old time that 'the whole medical art consists.' The institution of a final examination in clinical and practical medicine and surgery is a feature of the new scheme of the Royal Colleges which deserves especial mention, and the manner in which the fifth year of study is to be spent should make that period of your career the most interesting of all. It seems to me to give in a fitting manner a completeness to the curriculum not hitherto secured. With a few modifications, which experience may show to be necessary, the course thus laid down by the colleges may without exaggeration be said to be as academic as that of any university, and, this being so, it may seem to be a hardship that it does not lead to the possession of academic distinctions. When thirteen years ago I had the honour of acting in a similar capacity to the present I think that I was sanguine enough to say that there was no reason at all why the majority of the London medical students should not take London University degrees. I thought then—when perhaps the memory of my own student days was more fresh upon me—that one great reason for the singular paucity of London graduates lay in the equally singular ignorance concerning the University which would seem to exist in the schools of the country. But I have learnt since from a wider experience of other universities that this is not the sole reason, for although the number of

London graduates is yearly increasing, they still form a small minority of the London students; whereas in Edinburgh the reverse is the case. I take it that the grievance of the London medical student is established."

After detailing the history of the various proposals which have been made regarding the new London University, the lecturer proceeded: "It matters little what the solution is so long as the true interests of learning are kept in view and the welfare of the large numbers who come up to London every year to enter on the study of medicine. The time is approaching when something will be done to relieve the greatest city in the world of the reproach that it has no local organisation for higher education; and to the medical schools in particular one anticipates nothing but benefit from their union on common grounds within the *agis* of one university. Thereby medical education itself will be rendered more stable and more efficient. It would seem that the spirit of activity and unrest characteristic of the progress of the age is touching the subject in which we are most interested at present. This desire for improvement and perfection is a healthy sign, and although we may be living in the turmoil of transition we can look forward to a more peaceful period when under the new order the training demanded of those who are fitting themselves to be medical practitioners shall be founded on rational and scientific lines; for the desire of all must be that our profession should not fall behind in the race, but should continue as heretofore to lead the van in the great work of bettering the conditions of human existence. And for the individual practitioner a well-conceived and systematic course of training is of much more value than academic honours. If to knowledge he adds the common virtues of sympathy, of gentleness and of strength he will go forth to his daily contact with misery and suffering not only fully equipped for all emergencies and all trials, but with the consciousness that in his little corner of the earth he is doing something to brighten life and to assuage its woes. What higher vocation could be set before him—what could make to him life more worth living? That is the career which opens on many of you to-day, to which we welcome you, and in which we wish you all prosperity and honour."

#### UNIVERSITY COLLEGE, LONDON.

INTRODUCTORY ADDRESS BY MR. S. J. HUTCHINSON.

"LOOKING at the long roll of my distinguished predecessors, and at all the good and wise things they have said, I feel how difficult it is for me to deliver an address worthy of the occasion. To you I would most cordially say how we all are thoroughly in earnest in our desire to make your career here a pleasant and a successful one, and let me say in all friendliness that I personally, in common with many who have gone before me, look back upon the years I spent here as a student as perhaps the happiest portion of my life. It is a time when there are no responsibilities to speak of and few anxieties, except perhaps 'exams.' The simplest and best way to prepare for diploma examinations is to go in for class examinations. Of course I do not mean simply attending class examinations without previous preparation; but the whole ladder of medical education is arranged in such a manner now that by constant attendance on lectures and demonstrations and by careful note-taking, by working up the notes from text-books afterwards and by a rigorous attendance on the class examinations, the whole thing is made much simpler; the subjects, despite their increased number and extent, are more easily mastered and take a firmer hold on the memory, and are thus more available when wanted than when acquired by that pernicious system of spasmodic work, and still more by the popular but fallacious system of 'cramming' during the last few weeks before an examination. Since we met here last year many most important events have happened, not only in our college and hospital, but in the medical world generally. First of all, let me say that the building of the new hospital over the way may before long be confidently expected. A portion of the new hospital will probably be erected in the rear of the present buildings, and when completed patients would be transferred to it and a part of the old hospital removed to make room for further buildings. It will thus be seen that the number of beds will at no time be diminished nor the work of the school retarded in any way. Now, I do think all of us who are interested in University College, particularly those to whom the future belongs, must rejoice at this prospect and must feel a debt of gratitude to the

hospital committee, by whose zeal and untiring devotion this great work is so nearly consummated.

"The next important events which have happened since last year at this time are the reports of the Lords' Committee on Hospitals, and secondly the coming into force of the five years' curriculum for the Conjoint Board, and again the mountain has gone on labouring, but it has not yet brought forth the M.D. degree for London medical students. Let me urge upon every one of you the importance of striving for the 'best possible,' that is to say, make up your minds that you will take the highest degrees attainable—the M.D. or M.S. London, or the M.R.C.P. or F.R.C.S. Those of you who have had the incalculable advantage of a University career cannot be too thankful to your parents whose generosity and wisdom have given you this privilege, and you cannot better show and prove your gratitude than by turning such a training to its greatest advantage. There is always a certain fear of medical students acquiring a hospital manner, which however efficacious it may be in the exigencies of hospital practice, certainly does not suit in private practice. And this leads me to take advantage of this occasion to recommend you, gentlemen, at the outset of your career to cultivate a spirit of consideration towards the patients whom you are called upon to deal with during your studentship, and to behave towards them as far as possible as you would towards your own patients in private practice. You must forgive me if I allude to this, because I know from my own experience how easy it is to acquire certain little acerbities of manner which are meekly borne by the hospital patient, but which would be effectually resented by a private patient. Martial, the Latin poet, has said—

'I had, oh! Symmachus, a simple pain—  
You came, a hundred students in your train;  
A hundred probing fingers felt my brow;  
I had no fever then—I have it now!'

Besides all this, there are certain things to which it is worth your while to pay special attention. Need I say that I mean anatomy and physiology? To these I would add pathology in its widest sense. Without a thorough knowledge of these, the sciences of medicine and surgery are simply the 'baseless fabric of a vision.' It is well also to pay special attention to the art of prescribing. I say 'art' advisedly, for whilst brilliant skill in surgery—the *tactus cruditus* of the master—is the fine art of surgery, so is an efficient and palatable prescription the fine art of a skilful physician. I have alluded already to the burning question of a degree in medicine for London medical students. Now, the solution of this difficulty appears very simple, and I submit the suggestion for your earnest consideration, for probably the consummation will be in your hands, and not in ours. I say the solution is simply this: Let every medical practitioner who has duly gone through the curriculum ordained by the Medical Council and who has passed finally in medicine, surgery, and midwifery be thereafter legally entitled to style himself 'Doctor,' just as every clergyman or minister who has fulfilled the prescribed ordinances is styled 'Reverend.' The case is absolutely on all fours, and it would save an immense amount of trouble. I am aware that this scheme does not provide a university degree for London medical students, but it does provide a title for them, which they would not have to go away from London to procure. The State insists upon the medical student undergoing a five years' curriculum of severe study; it compels him to pass difficult examinations at all periods of his career, and then, when he has done everything and satisfied everybody and got his degree or diploma, what does the State do for him? Does it protect him in any way against the bonesetter, the herbalist, the medical electrician, the mesmerist, the midwife, or prescribing chemist, or the legion of American and other foreign gentlemen with a maybe bogus degree? Does it give him one single advantage over these gentlemen beyond allowing him the privilege of suing for his fee in the county court or being exempt from juries, of being placed on the Medical Register, of holding certain public offices and, most glorious privilege of all, it allows him to sign the death certificate when, 'at the last stage of all,' he is called in with the forlorn hope of restoring new life to the victim maybe of one or other of the practitioners I have named above. Now, I maintain that this is carrying the liberty of the subject a trifle too far, and I think the day is not far distant when it will be impossible for any of these gentry to practise any form of the healing art unless they are entitled to register.

"It would be well now to consider what the medical student had best do when he shall have duly and fully qualified, and

he will probably by that time have discovered whether he has developed any particular taste for, or proficiency in, any branch of the science of medicine or surgery, or if he prefers to work at some scientific subject, such as anatomy, physiology, or bacteriology. To those of you who desire or determine to become general practitioners, and such it is to be presumed the majority of you do, I should like to refer to the introductory address given here by Professor Victor Horsley in October, 1891, for you will there find some very practical and useful advice bearing on this subject, which it would be superfluous to reiterate. But there is one branch of practice which provides at this time a very satisfactory opening for such of you as are possessed of manual dexterity. The opening is afforded in dental surgery, a diploma being granted by the Royal College of Surgeons throughout the kingdom. Now, gentlemen, students of this college, you are singularly favoured in your opportunities for acquiring a knowledge of dental surgery on account of our proximity to two dental hospitals, one in Leicester-square and one in Great Portland-street. In face of these advantages it does not seem desirable for University College to follow the example of Guy's Hospital and establish a dental school within our halls, for whilst Guy's Hospital was more than two miles from any dental school, we are less than a mile from two. Perhaps enough has now been said about the student's work; let us devote a short time to the student's play. The advantages of a judicious admixture of play and work are so obvious that it is needless to dilate upon them. It is, however, the judicious admixture which is so important, for, like Mr. Pickwick's punch, it is possible to have too much of a good thing, and all I would venture to ask of you is this: do not neglect healthy exercise, but do not let it encroach on your work too much; go in for cricket, football, tennis, cycling, boating, anything you like, but play them for the love of them, not for 'cups' and 'pewters,' and, above all, do not in your games overtax your strength.

"I should like before I conclude to say one word about the invaluable help which physician and surgeon alike derives in the successful practice of their profession from skilful and attentive nursing, and whether in the hospital or the home, the nurse is almost as essential as the doctor, but only so far as she understands how to properly fulfil the instructions of the medical men. With regard to the social position of the medical man I am convinced that it depends entirely upon the man himself in the first place, for his education and his degrees or diplomas place him in the order of gentlemen, and it is his conduct and demeanour alone, which will enable him to remain in that honourable position or not, and to enjoy all its privileges or to be ostracised. Sir Thomas Watson once said on an occasion like this: 'The profession of medicine having for its end the common good of mankind, knows nothing of national enmities, of political strife, of sectarian divisions. Disease and pain, the sole conditions of its ministry, it is disquieted by no misgivings as to the justice or honesty of its client's cause, but dispenses its peculiar benefits without stint or scruple, to men of every country and party, and rank and religion, and to men of no religion at all; and like the quality of mercy, of which it is the handmaid, "it blesseth him that gives and him that takes," reading continually to our hearts the most impressive lessons, the most solemn warnings.' Surely you will not dare without adequate preparation to embark in such a calling as this, so capable of good if rightly used, so full of peril to yourselves and to mankind if administered ignorantly or unfaithfully. If you should be successful let it not make you presumptuous, but remember that in your most successful efforts you are but the honoured instrument of a Mightier Power—that, after all, it is 'God who healeth our diseases, and redeemeth our life from destruction.' In conclusion, let me again offer in the name of the Faculty of Medicine of University College a hearty welcome to those who join us to-day, good wishes to those who are in the midst of their work, and Godspeed to those who are going out into the world."

#### WESTMINSTER HOSPITAL.

##### INTRODUCTORY ADDRESS BY DR. MERCIER.

DR. MERCIER reviewed the altered relations of the medical profession to the public, first in regard to the relations of the individual doctor to each patient and then the relation of the profession as a whole to the rest of the community. In the first relation he remarked how the intercourse of doctor and patient had become less oracular and more confidential; how

the indiscriminating *sic volo sic jubeo* of the doctor had given place to a code of instructions whose reasons were imparted to the patient; how in the treatment of disease the doctor no longer contented himself with administering two tablespoonfuls of physic three times a day, a mode of treatment often little superior to that of wearing an amulet round the neck, but sought to take the whole mode of life of the patient into his hands and to modify and regulate it in accordance with the new conditions that the malady requires. The old view of disease that was now passing away regarded the patient as a body, some organ of which was deranged in its working. The new view regarded the patient as an acting, thinking, feeling man, whose power of acting, thinking and feeling was impaired and needed to be restored. The notion that our predecessors had of the body was much like that of an intelligent outsider might obtain of some great engineering workshop. They knew and understood nearly as well as we do the structure and working of the various organs of the body, of the machinery by which the work of the body is done; what they failed to appreciate was the nature and mode of action of the power by which the machinery was actuated and the work of the body performed. It is the working of this power, which resides in the nervous system, to which attention is now being directed, and the study of nervous action is rising continually more and more into prominence. Among the results of our increasing knowledge of the action of the nervous system and the altered views that begin to prevail with regard to what may be termed diseases of the body politic—maladies affecting the community itself—by which is meant not widespread maladies affecting large numbers of individuals, such as influenza or cholera, but disorders of the community which may coexist with a good standard of health in the individuals of which the community is composed, disorders which impair the efficiency of the social body, which impede it in its struggle to maintain its place among the nations, which diminish its welfare and retard its progress. Such social maladies are crime, pauperism and insanity. The lecturer contended that, different as these conditions are in superficial features, they exhibit upon close investigation such substantial similarity that they may be regarded as several branches of one stock. The pauper, the criminal and the lunatic are alike, it was contended, in being stragglers from the great army of civilisation. They have failed to keep pace with the great moving body to which they belong. They have fallen hopelessly to the rear and will perish by the wayside unless they are gathered into one of the three great ambulances that civilised States provide for their wounded and their inefficient, and which are called respectively the workhouse, the lunatic asylum and the gaol. An examination of the inmates of a workhouse would show that, exclusive of the sick, the children and the aged who might be termed accidental paupers, the remainder, or essential paupers, were so by reason of some defect of constitution, some want of intelligence, or of stability of character or some infirmity of temper or passion which, on the one hand, vitiates their capacity for labour or makes their labour unremunerative, and, on the other hand, allies them to the insane. A large proportion of these essential paupers will be found to be or to have been criminals, and a larger proportion to possess the instincts and habits of criminals. Of criminals, all, so long as they are in gaol, are of course paupers in fact, and a disproportionately large number are found to have obvious mental defects. In addition to these individuals, who border, and more than border, on insanity, it has been established beyond cavil by Lombroso and the school of criminal anthropologists that the criminal man is of a different physical organisation from the normal man, and resembles the lunatic in many respects. Lastly, while every insane person is potentially a pauper—that is to say, is incapable of supporting himself continuously by his own labour, all or nearly all the insane are potential criminals also; that is to say, their appreciation of their duty to their fellow men is so dim or so distorted that but for the restraining influence of asylum life they would bring themselves within the purview of the criminal law. It was further pointed out that there is a constant transference of individuals from one class to the other, and that the majority, for instance, of the insane have passed through the workhouse or the gaol; that while our gaols are being closed for want of inmates and pauperism is diminishing relatively to the population, lunatic asylums are being extended in all parts of the country. Finally, it was contended that the same remedial agent—compulsory employment—was used,

and was found efficacious in each of the three disorders; so that the poet's dictum, that "the lunatic, the lover and the poet are of imagination all compact," should read "the lunatic, the criminal and the pauper." The practical bearing of the view advocated was to be found in the modification of treatment that would follow if the close relationship of the three maladies were admitted. The process for admitting a lunatic to an asylum has already been assimilated to that for committing a criminal to goal. In both cases the detention is for a definite period, and at its termination the patient is discharged, quite irrespective of the state of his malady at the time. In the case of the lunatic the patient could be further detained if, in the opinion of his physician, he was not sufficiently recovered to render him a fit person to be entrusted with his liberty. In the case of the criminal this provision did not exist, and herein the criminal had the advantage of the lunatic; but whether the arrangement was equally advantageous to society was another matter. It was certain that if the reclamation of the criminal was to be effected the period of his detention must be indefinite in duration and must depend on the amelioration of his character. The value of these speculations from a medical point of view was claimed by the lecturer to consist in the broadened and more accurate conception that they afforded of the nature of insanity and allied disorders. It was not by poring through the microscopic that man could ever discover the reason for the existence of a delusion or be able to account for disorders of conduct. The explanation of such phenomena are to be found, not in visible structural peculiarities, but in the operation of biological and sociological laws; not in alterations of the brain, even though such alterations exist; but in the ancestral history of the individual, and in the complex interactions between the forces that animate him and the conditions in which he is placed. The lecturer concluded by inferring from these instances of non-success in life, the conditions that were necessary for success, and dealt with the respective shares of intellect and character in conducing to this result, cleverness, he said, was becoming commoner every day; it was almost a drug in the labour market. But character retained and would always retain its value. Strength of character, energy, courage and integrity were priceless qualities. They cannot be gotten for gold, neither shall silver be weighed for the price of them, and while men of brilliant intellect fail every day, men with these qualities can always command success.

#### THE COLLEGE OF STATE MEDICINE.

INTRODUCTORY ADDRESS BY SURGEON-GENERAL W. R. CORNISH, C.I.E., Q.P.H.

"THE medical schools of this country have a good old custom of opening the medical year with an introductory lecture, in which the students are advised as to what they should do and avoid doing in their training for the medical profession. In the course of my remarks I shall endeavour to give you a brief account of the origin and progress of the College of State Medicine and the aims of its founders, and to review from an independent standpoint the position and prospects of the public health medical service of this country; and, lastly, I shall submit to you a few observations regarding the great cholera epidemic, which is only kept at bay by the indefatigable vigilance and labour of our port and sanitary authorities. The College of State Medicine, in which we are to-day assembled, was established in 1886 and incorporated under a certificate from the Board of Trade in the year 1887. Its main objects are defined in the articles of association. The founders of the College of State Medicine may take this amount of credit to themselves, that they saw the defect in the existing system of education for public health officials and endeavoured to remedy it long before the General Medical Council framed its regulations for the granting of diplomas in Public Health. Since the General Medical Council has laid down rules for the guidance of medical men seeking to obtain Public Health diplomas—that is, in regard to all medical men registered subsequently to Jan. 1st, 1890—a large number of the London and provincial medical schools have established departments of teaching in public health, whether wisely or otherwise it is not for me to say; but the scheme of public health instruction adopted by the College of State Medicine has been followed by more than one of the medical schools, and as imitation is said to be the

sincerest form of flattery, the College may congratulate itself on its pioneer efforts being appreciated, even if the appreciation has taken the form of rivalry. Competition in sanitary education is, however, no evil in itself, and in the long run those institutions which combine the best theoretical with practical teaching will maintain their position; but it may be as well to state clearly that as not one medical man in twenty ever dreams of studying for a Public Health diploma, the multiplication of public health departments in medical schools is likely to result in financial loss to the organisers as well as a waste of teaching power. So far the founders of the College have limited their operations to the establishment of an institution for the training of gentlemen for the duties of health officers, and affording instruction in the methods of bacteriological research, but they do not intend to limit its operations to these subjects. State medicine includes more than hygiene and bacteriological inquiry, and the Council have only been deterred, by want of funds, from taking up other important work coming under the description of 'State Medicine.' There is, for instance, the very important subject of Mental Pathology, in which the great bulk of the members of the profession are but imperfectly trained, and in which a professorship would be desirable, if the Council could see its way to its establishment. Then, again, there is the great subject of Medical Jurisprudence and the investigation of cause of death by unnatural agencies, which subjects are supposed to be studied in the ordinary curricula of medical schools; but the daily reports of inquests appearing in the papers show these subjects to be very imperfectly taught, and more definite and practical teaching seems to be desirable. If only a fraction of the enormous wealth of this country, flowing in the broad streams of waste and prodigality, could be diverted to the narrow channels of education in sanitary principles and practice, the future of its inhabitants would be brighter and happier than it now is. A gentleman who prefers to remain anonymous has placed at the disposal of the College a sum of money sufficient to found a research scholarship for one year, and a candidate will be appointed in the course of the present month. The study of public health questions by the medical profession generally has been discouraged by the supineness or inaction of the recently appointed county councils, who, in the exercise of their authority, have not deemed it necessary, in the majority of instances, to avail themselves of their powers of appointing supervising medical officers of health of their respective areas. The 'may' of the English Local Government Act of 1888, instead of the 'shall' of the Scotch Act of 1890, has had the effect, temporarily at least, of discouraging medical men from qualifying for a public health career, and the neglect of local authorities to consolidate some of the smaller areas into workable districts sufficiently large for an officer giving his whole time to public health duties has still further tended to prevent men from devoting their attention to this branch of professional work. Although provision for the public health is more advanced in this country than in any other, it must not be concluded that everything has been done that might be done to ensure the health and longevity of the people. Legislation hitherto has aimed at throwing all the burden of provision for public health duties on local authorities, but it has not, in my view, adequately met the difficulty of insisting on local authorities respecting and practising the regulations laid down for their guidance. It is true that with well-grounded apprehensions of the approach of cholera an effort has been made to ascertain, by actual survey, the sanitary condition of many of the chief ports in regular communication with infected areas abroad. But this work ought to be undertaken, not only in regard to our first line of defence, but throughout the 1500 areas into which our sanitary defence is split up. Without in any way lessening the responsibilities of local authorities as defined by law, it is of the greatest importance that this sanitary survey of the country should be undertaken by the central Government and carried out on a defined plan. The great need of our sanitary system, in fact, is a closer touch between the controlling agency and the local authority. The vaccination laws of this and other civilised countries have been instituted in the general interests of the population, and for the protection of the public health, and where followed have succeeded in holding small-pox in abeyance, but experience has shown that these laws are systematically evaded by an increasing section of our people, and that many local authorities fail to use the legal powers entrusted to them for the public protection. The vaccination laws may or may not

need amending, but a very bad example is set by those local authorities who permit the law to be defied with impunity. All sanitary legislation must necessarily fail of its object if the fad or caprice of the individual is to be allowed to endanger and injure his neighbours. And this brings me to the consideration of the relations between the executive of the public health service and local sanitary authorities. In speaking of these relations I only attempt to give an individual opinion, biased, probably, to some extent by Indian experience. It is in accord with modern principles of legislation that the responsibility for obeying the law should rest with the local authority. The evil seems to be that the sanitary executive of the Government can take no steps on its own authority unless complaint is made, and supported by evidence, of neglect of the local authority. The Local Government Board has to deal with some 1500 local areas, some densely populated, and others very sparsely so. The consolidation of these areas and the employment of health officers unconnected with private practice, would seem to be a preferable way to carry out thoroughly the provisions of the Public Health Acts and of ensuring that sanitary supervision the public have the right to enjoy. In an ideal public health service we might expect to find all candidates entering by one portal, and liable to serve wherever the controlling authority might direct, the officers of the department being graded in accordance with the importance of their several spheres of work. In such a service we should expect the appointments to be permanent, subject to good behaviour, with a provision for retirement and old age; and although the local area should not be relieved of contribution towards the expense of such an ideal service, it should, in my opinion, have no voice in the choice or selection of the health officer, who should belong to a department presided over by a minister of health. It may be perhaps regarded as a sign of better times for men engaged in public health labours that the present Government has been pleased to appoint a member of the profession to the office of Parliamentary Secretary to the Local Government Board. In Sir Walter Foster we have a clear-headed and most excellent man of business who will bring the experience of a long professional life and sound acquaintance with the principles of sanitary legislation to the discharge of his new duties, and it is to be hoped to the amendment and improvement of the machinery of sanitary inspection and control. The epidemic of cholera which has been trying, so far in vain, to effect a lodgment in this country is one of peculiar interest to the student of epidemiology, and I will ask your attention for a brief space to discuss some of its features in relation to the probabilities of Great Britain being brought within the sphere of its influence at a later date. The present epidemic is perhaps the most remarkable of any that has been noticed, and, so far as its history is known, has moved faster than any previously recorded overflow into Europe from 1831 to the present time. All cholera epidemics, whether in India or Europe, have certain definite features as to time and place. There is in every case a period of invasion, a period of rekindling or recrudescence, and a period of decay, and these periods are usually completed within three years, when the contagium, or morbid material, appears to have exhausted its powers of reproduction, or for some other reason ceases to be active. Late information shows us that cholera was prevalent and fatal in Northern India about the end of 1891. It was certainly prevalent and fatal at the Hurdwar pilgrim gathering in March and April of the present year. It passed on to Cashmere in May and seems to have been most deadly in Afghanistan in April and May, from there to Persia in May and June, and crossing the Caspian Sea by trade routes it spread very generally throughout Asiatic and European Russia, and, attacking the German port of Hamburg in August, has, as the daily press keeps us informed, been carried to our own shores, and with almost the same rapidity across the Atlantic. It is the peculiarity of an invading epidemic to push on rapidly through new or uninfected populations. The movement is influenced by season and probably largely by temperature, for it never seems to be able to accomplish much headway during periods of frost and snow, but in the portion of country invaded by cholera seasonal changes bring about a revitalisation, or renewal of activity, and the epidemic may be more diffused or general in the second than in the first year of its introduction. The third year of a cholera epidemic is not so easy to describe. It may appear only in scattered localities and often in places but slightly or not at all affected in the first or second season, but in scarcely any locality does it survive beyond

the third year. The cholera invasions of Europe since 1866 have been mostly the fag ends of epidemics with no great vitality or inherent force of pushing on into new localities. Of this character probably was the cholera of Egypt of 1883 and of Spain in 1885-6. Of the enormous force and vigour of the present epidemic, the circumstances for its propagation being favourable, we may judge from what has occurred at Hamburg, where, out of a population of 600,000, the deaths from the middle of August up to date have been between 9000 and 10,000. The diffusion of cholera in Russia appears to have been very general from the capital on the Baltic to the Siberian coast and from the Caucasian districts to the extreme habitable north. With an epidemic so widely diffused it may be asked, Is it not possible that the germ or contagium may be exhausted in a single season, and that there may be no recrudescence in 1893? One would like to believe in such a possibility, but such belief would be in direct variance to the recorded history of previous epidemics of invasion which have not so quickly exhausted themselves. We are still very ignorant of the intimate nature of the cholera poison, but successive waves of epidemic invasion have taught us this much, that while no two epidemics are precisely alike in all points, yet in their main features there is very little difference between one epidemic and another. As cholera makes itself evident to us in one epidemic, so it will do in the next and the next, and from this peculiarity of the disease it is quite safe to anticipate that cholera invading a locality in any one year after a long period of absence will not absolutely leave that locality in the season of its invasion, but will remain to be revitalised, increasing or decreasing in accordance with surrounding conditions; so that those who look forward to seeing Europe clear of cholera in 1892 base their anticipations on some hazy notions in their own minds, and not on historical data. To have a clear perception of this feature of cholera is all important to sanitary officials. It teaches them that vigilance and precautions cannot be safely relaxed on the temporary cessation of local outbreaks, and that the measures necessary for the protection of the public health will have to be persevered in steadily while there is the possibility of an epidemic revival. The probability of keeping cholera out of this country and America is a question that comes home to all of us, and so far the first attack of the enemy in both countries has been, thanks to the splendid service of the port sanitary authorities, repulsed. The great danger I apprehend may occur on the relaxation of the precautionary measures and when the seasonal revival begins abroad. Now if there is one fact better established than another it is that the dejecta of a case of painless diarrhoea introduced into a new locality may be the means of a subsequent outbreak of cholera in such locality. In epidemic seasons like the present sanitary authorities cannot afford to give heed to names which tend to minimise danger. Such names ought not to be used in official reports of cholera. Their use is due chiefly to imperfect diagnosis and to the idea that every fatal issue of cholera must necessarily be preceded by collapse, cramps and suppression of urine, whereas a very considerable number of persons actually affected by the cholera virus never reach these stages of the disease, though the discharges from their bodies may, under certain conditions, be just as infective as those of the more advanced cases. It is in regard to the very insidious approach of cholera through the form of what may be thought a simple derangement of the bowels that communities in this country are most liable to become infected. We want and must continue to urge a sanitary stock-taking of the country, not by local officials according to their own notions of sanitary provision, but by an independent staff accustomed to such work. That a very large number of sanitary areas will pass such an ordeal with flying colours I make no doubt, but that a still larger proportion will be found defaulting in one or more particulars as regards the public safety is also, I think, very probable. At the present juncture we do not want to wait for the appearance of cholera, to hold investigation, but to determine by careful survey whether local areas are safe or unsafe as regards their sanitary arrangements. The sanitary survey of which I speak ought most certainly to include an account of our rivers and streams. The way in which our water sources have been treated is a standing disgrace to the country. Numberless commissions and committees have reported on the pollution of rivers, but practically nothing is done to remedy the evils resulting from manufacturers turning their waste products into running streams and the use of such streams as sewage receptacles. Clean, wholesome water is as much

a necessity of human life as clean, pure air, and the deflers of both have much to answer for in regard to preventable sickness and premature death. In the preventive medical service of your country you will find ample scope for all your best energies. You deal with human life in the aggregate, and whatever you may be able to effect, in the way of attaining higher standards of cleanliness, in air, food and water, will be for the benefit of thousands, instead of the units who fall into the hands of the practising physician. You will lose no opportunity of advancing your knowledge or of applying the daily advance of science to the perfecting of your methods; and if ever the glorious time is to come when men and women shall die of old age, just as ripe fruit falls, and enjoy long and healthy days, you will have the satisfaction of knowing that sanitary science, which has already appreciably added to the longevity of human life, and to which you give your loving duty and service, has been the chief factor."

#### THE ROYAL VETERINARY COLLEGE.

##### INTRODUCTORY ADDRESS BY PROFESSOR MCFADYEN.

The lecture was devoted to a review of the growth of veterinary pathology during the past twenty years. The lecturer said that there was no exaggeration in the statement that within the period specified veterinary science had made a greater advance than it did during the preceding eighty years. Every branch of veterinary knowledge had shared in this advance, but in none had the progress been so rapid as in the domain of pathology. Pathological research had discovered new diseases, had revolutionised the views formerly held regarding many others, and was pointing the way to methods of cure and prevention that were scarcely dreamt of two decades ago. Taking as an illustration tuberculosis, it was pointed out that twenty years ago this disease was generally ascribed to some mysterious quality of the tissues in certain breeds and individuals, in consequence of which almost any irritant, such as would in other individuals excite merely a transitory inflammation, might serve to light up a degenerative or destructive process capable of spreading throughout the whole body. It was not then generally admitted by veterinary surgeons—in this country, at any rate—that it was contagious or infectious, but they believed that the disease might be generated in various ways, such as by close breeding, exposure or improper feeding. At the present day, on the other hand, they had no need to speculate regarding the cause of tuberculosis. It had been proved beyond the possibility of doubt that tuberculosis was caused by the introduction into the system of a vegetable parasite or germ, and the disease had now to be classed with the contagious maladies. They knew further that tuberculosis was identical with the disease termed "consumption" in the human subject, and they had to reckon with the possibility of the disease being transmitted from the one species to the other. Anthrax afforded another illustration of the revolution which had been effected regarding the cause of important diseases. In text-books published less than twenty years ago anthrax was vaguely described as a disease in which there was a sudden change in the physical characters and physiological properties of the blood. It was believed that it originated spontaneously, and that geographical, climatic and dietetic conditions played an important rôle in its production. Furthermore, it was regarded as a disease that assumed many forms, the two best known in cattle being splenic fever and black leg. Every one of these notions has had to be discarded. Anthrax was now known to be, like tuberculosis, a disease that owned but one cause—viz., the entrance into the body of a vegetable organism—the anthrax bacillus. The so-called black leg, formerly regarded as a form of anthrax, was now known to be a perfectly distinct disease, caused by another bacillus, which, broadly speaking, was as different from the germ of anthrax as a sheep was from a goat. Glanders, again, was a disease regarding whose cause they had acquired positive assurance only within the last few years. It, too, was formerly regarded as a disease that had various causes, and that sometimes originated spontaneously, but it was now known that every case of glanders was due to infection with a germ derived from some antecedent case of the disease. But perhaps the disease regarding whose nature and cause the most complete revolution of opinion had been effected within the past few years was tetanus or lock-jaw—a disease which, from the suffering that it caused and its almost invariably fatal termination, ranked as one of the most terrible maladies of man and the lower animals. In books

published twenty years ago there could not be found the barest suggestion that this disease might be due to a germ, and yet it was well known to-day that the locking of the jaw from which the disease derived its popular name was due to the action of a deadly poison elaborated in the wound by a bacillus. After referring briefly to actinomycosis, strangles and other diseases the causal microbes of which had recently been discovered, the lecturer proceeded to notice how much knowledge had been gained regarding the means of curing and preventing diseases by a minute study of their pathology. It was a truism that the discovery of the cause of a disease was the first step towards the discovery of the means of cure or prevention. It had, perhaps, to be confessed that the discovery of remedies has yet lagged a long way behind the discovery of causes; but still, magnificent results had already been achieved in the case of some diseases. As an example, the Pasteurian method of protecting animals against anthrax by means of attenuated cultures of the anthrax bacillus was cited—a method which, it was stated, had during the last ten years saved many thousands of pounds annually to the stock-owners in France. Similar methods had, with more or less success, been applied to combat several other diseases. At the present time they appeared to be on the threshold of still greater discoveries regarding the means of combating diseases that had hitherto defied every therapeutic effort. It had recently been shown that it was possible to protect even horses against tetanus by the use of what was termed a "chemical vaccin," and the blood serum of animals thus protected was found to be capable of conferring immunity when injected into other animals. What was still more remarkable, and pregnant with promise of the most beneficent results to both man and the lower animals, it had been discovered that the blood serum of horses thus artificially rendered immune against tetanus was actually curative when injected into animals affected with tetanus. But even in those cases where the discovery of the cause of the disease had not yet been followed by the discovery of anything of the nature of a protective or curative "vaccin," the position to-day was infinitely better than before. Take, for example, the case of tuberculosis. There was unfortunately no known cure or preventive for that disease, but the discovery of Koch's bacillus and the study of its life-history had given clear notions regarding the manner in which the disease was spread, and pointed the way to confine its ravages, and possibly even to stamp it out. In the concluding part of the address Professor McFadyen discussed the place that the study of pathology ought to occupy in the education of the veterinary student. He said that it was time that they gave up the notion that every veterinary surgeon who "knew a horse" and could diagnose lameness was a "good practical man." The veterinarian who wished to deserve that name could not afford to be ignorant regarding pathology or bacteriology. At the present day a veterinary surgeon might easily bring discredit on himself and even endanger human life through errors in diagnosis from which a little bacteriological knowledge might have kept him free. It would be folly to expect every veterinary graduate to be able to carry out a difficult piece of pathological research; but although it was not expected that a veterinary practitioner should be able to carry out a chemical analysis in a case of poisoning, the study of chemistry was considered a most essential part of the veterinary curriculum. And so it ought to be with pathology, which deserved to be taught, theoretically and practically, to as full an extent as chemistry or any other branch of knowledge included in the professional education. At the present time this was not possible, for the simple reason that the three years of study prescribed did not admit of justice being done to the teaching of pathology without curtailing the time that had to be devoted to other subjects. The present was the last session during which a student could enter under the three years system. After that the veterinary curriculum would extend to four years, and every teacher ought to hail with satisfaction the near advent of the new arrangement, under which it would be possible to give a course of instruction in keeping with the times and adequate to the requirements of modern practice. Allusion was also made to the foundation of the chair of Comparative Pathology in the Royal Veterinary College by the Royal Agricultural Society. The lecturer said that this step could not fail to give a much needed stimulus to the study of veterinary pathology in Great Britain—a study which could not fail to bring knowledge of great value in their struggle with animal diseases, and which might also throw light on the cause and treatment of human maladies.

## OWENS COLLEGE, MANCHESTER.

## INTRODUCTORY ADDRESS BY DR. BROADBENT.

THE lecturer took as the subject of his address the Intellectual Interest of the Study and Practice of Medicine. Prefacing his remarks by an appreciative reference to the late Professors Morgan and Ross, he gave a rapid summary of his reminiscences of Manchester medical schools, and then entered on the main question he set himself to discuss. "What," he said, "are the conditions of happiness in a man's life, and how far are these satisfied by a medical career? The first is satisfaction of the ordinary wants—the enjoyment of the simpler comforts and freedom from care for the future of himself and his family. Unfortunately, I cannot say that the medical profession affords all of us such a livelihood as to assure us from pecuniary anxiety and the means of providing for a family; but I can say that the general level of comfort and security among medical men is high and the proportion of wrecks and failures low. What is it which, to those who are mentally and morally fitted for it and who enter it from genuine inclination, makes the medical profession the happiest career a man can choose? For such it really is. To this I answer, first and foremost the opportunity for free and continuous exercise of the intellectual faculties. With the elevation of the race have been developed intellectual appetites. There is a hunger and thirst after knowledge and a passionate desire for achievement, and the pleasure and satisfaction attending the attainment and employment of knowledge are as much higher and more durable than the gratification of the senses as mind is higher than body—as intellectual operations are superior to sensation. All the sciences are laid under contribution by medicine. As you master the principles of chemical structure and affinity, as you come to understand the relation between chemical action and the absorption or evolution of energy, thermal, electrical, and nervous, your ideas are enlarged, your imagination is excited, and the intellectual interest is awakened, which is gratified at each further step you take, but never satisfied. Pathology at the present moment surpasses in interest every other department of study and research. For a long time it was almost identified with morbid anatomy, and concerned itself chiefly with results; but it has emerged from this stage, and the attention of the new school of pathologists is concentrated upon processes, and the method of experiment in their hands is yielding results of surprising value and importance. The discussion before the Pathological Society on phagocytosis was as exciting as a debate in Parliament, and the combats between the cells and invading bacteria as realistic as one of Homer's battles. A septic wound is made, the leucocytes crowd to the spot, block up the avenues by which the hostile bacteria seek to gain entrance into the lymph spaces, and engulf and destroy them, the bacteria at the same time multiplying with amazing rapidity, and endeavouring to disintegrate the cells and to force a passage. This local war is defensive inflammation. If from any cause—the amount of virulence of the infective inoculation, or, in other words, the number, character or activity of the microbes, or, on the other hand, the imperfect afflux or defective vigour of the phagocytes—that is, the inadequate local reaction—the line of demarcation and limitation is imperfectly drawn, the microbes obtain access to the circulation, and in the blood and fluids find an unlimited supply of food and unbounded opportunities of multiplying. It has been known ever since post-mortem examinations were first made or dissection was practised that if a dissection wound were followed by inflammation and abscess the mischief would probably not go further, but that if there were only a little pain at the seat of the cut or puncture, while the lymphatic channels and glands became swollen and painful, fatal septicæmia or pyæmia was probably impending; but it is only now that the defensive process can be understood and explained.

"When I was a student the name zymotic disease had, it is true, obtained a footing in medical terminology, but under protest from many distinguished men who distrusted theory of all kinds. It was pointed out that the analogy between the action of yeast on a solution of sugar and the course of a fever was but weak at best, and was open to the objection that the successive stages of incubation, invasion and decline might represent not the life and work and organism in the system, but the stages of the reaction of the system. Especially were we warned against basing treatment upon such uncertain grounds. Now we know that the parallel holds good down to the smallest particular, just as the yeast grows and

multiplies with extraordinary rapidity, splitting up the sugar into carbonic acid and alcohol till its further progress is arrested by the alcohol which is a product of its own activity, so the bacteria multiply at the expense of the fluids of the body, form ptomaines which, like alcohol, act as poisons to the nervous system, and which, again, like alcohol, bring the action of the microbes to an end. Our methods of protection against fevers are now entirely derived from definite knowledge of the life-history of the bacteria or microbes by which they are caused, and our treatment will be more and more determined by such knowledge. We are shown, also, how the defensive processes may be reinforced or impaired. It is well known that drunkards fall ready victims to fever, erysipelas, and septic diseases generally, and the general deterioration of the tissues produced by alcoholic excess has been accepted as a sufficient explanation. But this, while true, is not the whole truth. A bacteria culture of a given kind and degree of virulence is injected under the skin of a rabbit, local inflammation, and perhaps abscess follows, but the animal does not fall a victim to the poison. In another rabbit, or in the same at another time, an injection of the same kind is made, but simultaneously a dose of chloral is injected into some remote part of the body; the local reaction is imperfect, general infection rapidly takes place, and the creature very soon dies. What is the reason? It is that chloral paralyses the leucocytes. They cease to display their wonted activity; examined on the warm stage, instead of pushing out pseudopodia in every direction and undergoing frequent changes of shape, as is observed in the normal state, they are sluggish and retain a spherical form. When bacteria, therefore, are introduced into the subcutaneous tissue, they take no notice of them, but remain perfectly passive, and leave the way open into the lymphatic spaces, whence the invaders pass into the circulation, carrying destruction to every organ of the animal's body. Now alcohol in excess has a similar action on the leucocytes, and this, as well as the deteriorating influence on the tissues of chronic alcoholism, predisposes to septic infection. A single debauch, therefore, may open the door to fever or erysipelas. Protective inoculations against various diseases have been discovered, and had it not been for the ill-judged restrictions on experiment which have deprived this country of the precedence in research which would have been earned for it by the zeal and insight of our young experimental pathologists, we might perhaps already be in the possession of protection against scarlet fever, diphtheria, and other diseases, which would do for this country in saving the lives of children what has been done for France in protecting sheep and cattle from anthrax, preventing the loss of hundreds of thousands of pounds to its agriculturists. We have at length, thanks to experiments on animals, learnt the true nature of phthisis and how it is propagated, and we can now not only direct our efforts to strengthening the constitution so as to render the soil unfit, but to the destruction of the seeds. In this respect Owens College, as represented by Dr. Ransome, occupies a leading position. Here our difficulty will arise from the apathy and carelessness of individual members of the committee. In politics, and in all other departments of public life, no honourable antagonist thinks of imputing motives. In experimental pathology all our motives are found for us, one worse than another, and we are allowed no credit whatever for a desire to alleviate the sufferings of men and animals; the very highest motive with which we are credited is scientific curiosity, and by this is really meant scientific cruelty. You may drown a superfluous puppy, but if you do it with a view to experiments as to how animation may be restored, you place yourselves within the grasp of the law.

"Scepticism in the sense of a general disbelief in the efficacy of remedies, which was formerly not uncommon, and was, indeed, the mark of the 'superior person' in medicine, becomes every day more unjustifiable. At one time, indeed, there was a great gulf fixed between science and practice. Chemistry, physiology and even pathology were left behind at the door of the hospital ward—were indeed by some carefully shut out. With some few exceptions, and these distrusted, there was no connecting link between chemistry or physiology and therapeutics. The symptoms of disease and the influence of remedies were facts of observation pure and simple, to which it was unsafe to apply reasoning or conclusions drawn from science of any kind. But this is no longer the case. When pathologists were in the habit of looking only at the effects of disease—at lungs riddled with cavities at the liver and kidneys shrunken and hardened by

fibroid change, at the brain torn by a hæmorrhage—they might scoff at the efforts of the therapist to deal with such conditions, but they have all had a starting-point, and the patients who have ultimately died have lived through all the stages which have culminated in the ruin displayed on the post-mortem table, while this same post-mortem table has displayed scores of instances in which similar disease has been arrested at one or other of these stages. Processes are now the chief object of study and research, and in proportion as these are understood power will be gained of intervening and counteracting. As we learn how to set in motion morbid changes we learn how they may be arrested. It is in functional derangements that organic disease begins, in dynamic influences that structural changes have their origin. Perturbation in the activity of cells is brought about by deviations from the normal composition of the blood. Now we can at will introduce into the blood substances which can influence the activity in one direction or another of every cell in the body; we can intensify or suspend the influence and control of the nervous system over organic operations, and it is our own fault if we cannot employ these tremendous powers for the advantage of our patients. It is true that at present our comprehension of the ultimate mode of action of remedies is very imperfect, and that we have still to be guided by the flickering light of experience rather than by the broad daylight of science, and it is true that experience is uncertain and at times misleading.

"An enormous step towards the comprehension of the mode of action of remedies has been made in the discovery of the antipyretic class of substances. In these, as in chloral, the chemical constitution of a drug is a clue to its effects, so that from the chemical constitution the effects can be predicted, and our scientific chemists know in what direction to push their endeavours in order to obtain a safer or more powerful substance. When this is fully worked out, and we know not only the factor in the drug, by variations of which the results are influenced, but the exact way in which the chemistry of the system is modified and the heat-producing reactions between blood and tissue are restrained, we shall have obtained knowledge going far beyond what we now possess. In the meantime this tremendous power of lowering the temperature and of relieving certain kinds of pain placed in our hands by these substances is, I fear, thoughtlessly and recklessly employed. We have so long looked upon a high temperature as denoting the intensity of acute disease, and as an indication of the danger attending it, that the lowering of the temperature has almost come to be considered equivalent to the cure of the disease, whereas not infrequently the patient is knocked down as well as the pyrexia, and in any case we ought to bear in mind that we are dealing with an effect and not with the cause, and that, unless the effect is itself a danger, we may be doing more harm than good. We may actually be interfering with a defensive reaction. So common is the abuse of anti-pyretics, that, from time to time in cases admitted into hospital, the drug has to be diagnosed as well as the disease.

"In what way is the study of medicine to be undertaken? No general recommendation could be made which would apply to all; one intellect is analytical, another constructive; one is characterised by receptivity and the faculty of storing up impressions and facts, another by lucidity in perceiving the relations which underlie phenomena; one man ponders slowly, another is instant in action. Memory, the very basis of intellectual operations, varies not only in degree but in kind; in one the memory is visual and a man retains only what he sees, while he thinks in pictures, in another it is auditory and he learns by lectures and thinks in verbal associations. You will have to find out for yourselves what method of working suits you best. While I do not interfere with the function of your teachers by recommendations as to the order and method of your studies, I may speak of the spirit in which they should be pursued and of the object you should keep before you. Professor Huxley—let me give him the title recently conferred upon him, but long held by him in our esteem, the Right Honourable Professor Huxley—in one of his lay sermons on education makes this the burden of his exhortation: 'Learn what is true, in order that you may do what is right.' Now, if this applies to the self-training of a man for the ordinary duties of life, it applies with special force to preparation for the medical profession. The sentence might have been devised as a motto for medical students, 'Learn that which is true, in order that you may do that which is right,' and I hope some of you will adopt it and live up to it."

## SHEFFIELD MEDICAL SCHOOL.

## INTRODUCTORY ADDRESS BY DR. DUNCAN BURGESS.

DR. BURGESS, in speaking of preliminary qualifications, referred to the ideal pupil of the old Sanskrit writers. According to the Hippocratic law "to acquire a competent knowledge of medicine, first of all a natural talent is required." The time of Hippocrates was the age of Pericles. Then no guarantee of general education or culture was required in Athens at all events; but when Galen practised in Rome in the second century of the Christian era a preliminary examination was wanted badly. For cooks and cobblers were made doctors in six months. In ancient times care was taken to exclude pupils in bad health or with obvious defects. A high standard of bodily vigour would have deprived the profession in this country of some of its greatest ornaments. The first definite course of preliminary study was that of the school of Salerno in the thirteenth century. No one was permitted to study medicine then until he had studied logic for three years. The lecturer said: "A sound general education is the only introduction to the medical curriculum demanded by our General Council. A boy, therefore, who is intended for the profession should not be made the victim of peculiar theories of education. He should be sent to a good school where he will get the mental and bodily training best suited for him, and therefore for any calling or profession he may adopt. If, when he has reached years of discretion, he cannot give his whole heart to medicine and make it the chief end of his life, he should on no account become a medical student." In speaking of the new curriculum the recognition of physics was considered a great improvement. The thorough and precise work and the accurate reasoning which characterise the exact sciences should give the medical student an invaluable training. The audience were reminded that Thomas Young, whose name occupies the most distinguished place in the history of physical optics, was a London physician; and that Helmholtz, who stands beside Lord Kelvin pre-eminent among living physicists, is a doctor of medicine. The provision in the new regulations for partially resuscitating the old system of pupilage was considered a mistake in its present form. A student would become the pupil of a registered medical practitioner to get little practical tips and useful "wrinkles" and to be made a man of the world. During the time thus occupied a formidable examination in medicine, midwifery and surgery would be hanging over his head. The degree or other title which qualifies for the Medical Register might be deferred for six months or even a year after the final examination. This interval might be profitably spent with a suitable practitioner. Probably the most valuable way of occupying it would be by residing in a general hospital as assistant house surgeon. But it might be very advantageously employed in London, at the Rotundo Hospital, Dublin, or on the Continent. The standard of the qualifying examinations has been raised by the control exercised by the General Medical Council over the multifarious licensing bodies. A State examination such as exists in the German Empire would be far simpler and much more satisfactory than the condition of things here. There should be no royal or easy road to the Medical Register. In each of the three kingdoms the same State examinations should be passed. After alluding to the first institution of medical schools in ancient Egypt and to the magnificent museum of Alexandria and to the work done by the Arabs, the lecturer then went on to say: "In the universities of the Middle Ages, wherever a medical faculty was encouraged and helped famous teachers attracted pupils from distant countries. Unfortunately medicine was not properly recognised by the English universities, and the trade marks of the corporations, formed to remedy this neglect, have been too plainly stamped on our profession. The benefactors of the famous Italian schools were animated by a very catholic spirit. The magnificent academy at Bologna was dedicated to the whole world. We are proud of Harvey, but his famous discovery was clearly the outcome of the opportunities he enjoyed during the five years he passed at Padua. For the great anatomist, Vesalius, who described the valves, the changes of form and the movements of the heart, was one of the celebrated line of Paduan professors. His pupil and successor established the pulmonary circulation as an inductive truth. And it was at Padua that Harvey had the valves of the veins demonstrated to him by his master Fabricius, who had then only recently made this important observation. The University of Paris, on which the Universities of Scotland have been

modelled, may be cited to show what France has done in the past for medical education. At the present time the Republic spares no expense on its medical schools. According to Puschmann, the salaries of the medical faculty in Paris alone amount to 700,000 francs a year. Hospitals, class-rooms and laboratories are all furnished on the same liberal scale. Enumerate the universities of the German empire, count the professors if you can, inspect the institutes and libraries with their crowds of paid attendants and costly contents, and you will be simply amazed at the liberality of the various Governments. The Emperor of Austria is equally generous. In Vienna the new University buildings vie in magnificence and architectural effect with the opera, the theatre, the town hall, the Parliament house and the Imperial museums in that city of splendid palaces. To contrast with all this the meanness of the richest nation on earth, I must appeal to Ruskin. What he said years ago is still true. We are still glad enough to make our profit out of science. We snap up anything in the way of a scientific bone that has meat on it eagerly enough, but if the scientific man comes for a bone or crust to us that is another story. Ruskin's famous illustration of the gentleman who professes to be fond of science, and who spends £2000 a year on his park but refuses to give 7d. for a unique collection of fossils is too flattering an illustration of what we publicly do for medicine. Registration fees are imposed on medical men at the outset of their career to pay the expenses of the Crown representatives on the Medical Council and to keep a Medical Register for the convenience and protection of the public. Moreover, zealous and able workers who are eager to promote researches at their own expense are forbidden by law to work on the only lines likely to yield useful results." The subjects of the Sheffield Medical School and the new public hospital occupied most of the latter part of the address. The lecturer, after quoting from Dr. Latham's "Clinical Medicine," concluded by saying: "If you follow Dr. Latham's advice you will do more than command success, you will deserve it. Success with honour is worth striving for. May it be yours ere your courage is daunted by hope deferred that maketh the heart sick. Remember the death-bed message of Dr. Wilson Fox to his students, 'Tell them the surest road to success is to have a high standard of right and honour and to adhere strictly to it.'"

## MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

## INTRODUCTORY ADDRESS BY DR. L. HEPESTAL ORMSBY.

THE lecturer, after a few introductory remarks, took for his subjects (1) A Few of the Grievances of the Medical Profession, and (2) The Five Years' Preliminary Study for a Medical Career. The second section of the address was, however, dealt with first. Having enumerated the recommendations of the General Medical Council on professional education and examinations, Dr. Ormsby proceeded to state the reasons which induced the Medical Council to institute a fifth year of study. "First, owing to the many subjects which have to be studied nowadays compared with five-and-twenty years ago, it was considered there was not time given to allow the student to master sufficiently every subject in the curriculum. Secondly, the facilities of entering the profession and the short time spent in its study led to the overcrowding of qualified men far beyond the necessary requirements. It has been said that it requires a population of at least 1800 to support each physician, giving him a fair and ample income. There are in some countries nearly twice as many physicians qualified as there is room for. In America, there is one physician for every 600 inhabitants, to say nothing about the numberless varieties of chemists and druggists who flood the country and engage more or less in practice. In England there is one physician for every 1500 persons, in France one for every 1814; in Austria one for every 2500, in Germany one for every 3000, in Italy one for every 3500. Much can be said, however, on the other side regarding the medical practical education of the last century and early in the present one. Many of our physicians and surgeons in this country who were qualified forty or fifty years ago aver that the men are not better physicians nowadays (with the numberless subjects which are crowded on their already overtaxed brains) than the qualified men of their own day. A hundred years ago there were great men in our profession with very limited advantages and opportunities. Consider for a moment what giants they would

have been had they lived now—which proves that a physician or surgeon must be born with the ability and natural aptitude for his profession and not made by a system of brain-stuffing and other artificial processes. The clever, intelligent student will be able to absorb the required information in two or three years which will take the dull or indolent one five years or more to acquire. Again, the education will be far more expensive to the parent, as it will probably entail the keeping of the student in a city or medical centre of learning for another year, with the accompanying weekly expenses of such a residence. This of course is of no consequence to the public, but it will no doubt press heavily on many impecunious parents. The five years' period of study will only apply to those students who have commenced their studies after Jan. 1st, 1892."

The lecturer then proceeded to discuss various matters falling under the second section of his address. The first grievance brought under notice was the uncertainty of superannuation in the case of Irish dispensary medical officers. "What inducement," said the speaker, "is there for highly qualified medical men to enter the service when they know that after forty or fifty years of hard and incessant work they must depend on the whims and tempers of a set of guardians to grant them a small pittance by way of superannuation to keep them in some comfort for the remaining years of their life? The present Superannuation Act has one word (*may*) which in any future legislation requires to be changed into *must* or *shall*. When that is done the guardians will have no choice in the matter, as it will then be obligatory on them to grant to all worn-out officers in the Poor-law service their just and well-earned retiring allowance. Who has not heard of the glaring case of Dr. Walsh of Ballyshannon, aged eighty-five, who, from increasing infirmities, the result of age, had to resign his dispensary and throw himself on the mercy of the guardians, who, up to the present, have not granted him one penny retiring allowance? Is this right or human in a civilised country? Yet year after year this gross and scandalous system is allowed to continue and old and worn-out dispensary medical officers are constantly to be seen at all hours of the day and night, in sleet and snow, pursuing their beneficent work in miserable cabins on sides of mountains at a time when many of their masters—the guardians—are enveloped in comfort, luxury and sleep. After a life spent in such circumstances the doctor need not look with confidence to a pension. Some boards of guardians have given the smallest retiring allowance they could, others have persistently refused to give any at all. There is no law to compel them. The doctor must resign before his application can be considered, and therefore a number of them hold on until they die in harness."

The next grievance Dr. Ormsby brought before his hearers was the exclusion of Irish and Scotch diplomates from English appointments. "What!" said the lecturer, "am I to be told that, with what Englishmen boast of—*fair play*—they tolerate a system of exclusion of Irish and Scotch diplomates from their appointments, although the same system of examination is held in the three countries, arranged and sanctioned by the General Medical Council, which is the body appointed by the Crown; the licensing bodies and the rank and file of the profession in the three countries to arrange uniform curricula and uniform final test examinations? The question is a very important one and has received the serious attention of many influential bodies. The Irish Medical Association, the British Medical Association, the Irish Medical Schools and Graduates' Association are all in line on the subject, and by their combined strenuous efforts in the direction of justice and British fair play have induced the governors of the Bristol General Hospital and the East Sussex Hospital, Hastings, to expunge from their by-laws this unfair and un-British-like disability. . . . Very recently—within the last three months—a friend of mine, a very able and accomplished surgeon, holding the Fellowship of the Irish Royal College of Surgeons, became a candidate for the assistant surgeoncy of a London hospital. Each candidate on the day of election was called in and interrogated by the governor of the institution, and the following dialogue took place between the governor and my friend:—Governor (in the chair): Mr. —, you are a candidate for the post of assistant surgeon of this hospital?—Candidate: Yes.—Governor: You have read all the regulations necessary for candidates to comply with?—Candidate: Yes.—Governor: What qualifications do you hold?—Candidate: I hold the Fellowship of the Royal College of Surgeons in Ireland.—Governor: Well, sir, we regret very much, but holding such a qualification you are ineligible as a candi-

date for the assistant surgeoncy of this hospital, and we must strike your name off the list of candidates.' I presume if I were a candidate to-morrow for the surgeoncy of a London hospital I would meet with the same rebuff, because I hold by a hard and stringent examination the Fellowship of the Dublin College of Surgeons." Another grievance spoken of by the lecturer was one in connexion with the Army Medical Service. For though, he said, the hardships formerly complained of by that service had to a large extent been removed, there still remained one requiring attention—namely, "the meagre and miserable name by which the Army Medical Service is known—namely, Medical Staff—a meaningless term. It might just as well be civil as military. I know when the Army Medical Service was made a departmental system in 1873 every army surgeon was sure it would be raised to a 'Royal Corps.' We have Royal Engineers, a corps more like the Army Medical Service than any other in work and division of labour. Then there is the Royal Artillery, Royal Marines, and many other regiments termed Royal, but the moment it is proposed to confer it on doctors prejudice and class feeling intervene between the Queen's wishes and her faithful servants in the Medical Service. In 1883 Lord Morley's Committee recommended that the Medical Service should be made a Royal corps, but it was again refused. The doctor class apparently has to work hard, but need never think of being honoured or rewarded. I do not like to prophesy, but I am inclined to think that before long you will see the service termed, as it in all justice ought to be, Royal Medical Staff. And by making the service Royal its *esprit de corps* would be increased and better officers would join it, and so its efficiency and social position would be improved. On the subject of foreign service a great injustice is practised on the army doctor. Till very recently he was compelled to remain only five years on foreign service. Now, however, an additional year has been put upon him, serving as he may have to do in the worst of climates or in a fever- or cholera-stricken district, whereas the Royal Engineers used to serve seven years abroad, but now this has been reduced to five. Where is the justice of this interchange?"

The exclusion of members of the profession from the peerage and the appointment of a Cabinet Minister of Health and Sanitary Science then came under notice in connexion with the elevation to the peerage of Sir Lyon Playfair, and the appointment of Sir Walter Foster by Mr. Gladstone as Parliamentary Secretary of the Local Government Board, this being the first occasion upon which any member of the medical profession has been appointed by the Sovereign as a member of the Government. "In the constitution of our governmental system," said Dr. Ormsby, "there should be (and it is imperatively called for) the Minister of Health and Sanitary Science, who should occupy a seat in the Cabinet, to be only filled by a physician or surgeon of eminence and ability. . . . I also fail to see why the profession of medicine should not hold at least as high a place in the public estimation, and therefore in that of the State, as any other profession. Why is England so sadly behind other countries in this respect? Look, for instance, how the profession is treated in Germany. There, when the medical man has earned by his labours for the public good the recognition of his monarch, he receives a patent of nobility and a high place in the social system, because he is a man of science and extended knowledge. Is the arbitrary word 'precedent' always to exclude men who happen to embrace medicine as a profession, who possess in many instances far bluer blood and a far more ancient and honourable pedigree than many of the members of modern society now called aristocracy? Statesmen in exalted positions are frequently in the habit of making use of statements which they either do not mean or seem not to have the moral courage to carry into effect. For it seems to me that nothing but the blindest prejudice—a prejudice unworthy of enlightened and honest men—can have so long stayed the hand of the Sovereign and prevented the elevation of representative men of our order to seats in the Upper House, which Lord Salisbury once told the country was chiefly valuable because it represented success in all lines of public usefulness, from commerce to statesmanship. It is a great honour to be Prime Minister, but it is even a greater distinction to be Prime Minister in one's eighty-third year, probably the first example of the kind in history. If medical science has had anything to do with Mr. Gladstone's health, and consequently of his position to-day—and who can doubt that it has had much, owing to the care taken of it by Sir Andrew Clark—what higher duty can devolve upon him as Prime Minister than to mark his assumption of office be

advising the Queen to at last do justice to medicine by creating at least two medical peers, Sir William Jenner and Sir James Paget, a physician and a surgeon respectively of world-wide reputation, who have personally well deserved the honour, and the medical profession at large would be ennobled by their elevation."

In the same strain the lecturer referred to the almost entire exclusion of medical men from seats on the Privy Council in England and Ireland. He remarked that England is in advance of Ireland in some degree, for within a few months one of our order, a Fellow of the College of Surgeons of England, has been advanced to the position of a Privy Councillor in the person of Thomas Henry Huxley, F.R.S. Now that England had recognised the claims of the medical profession in this respect, he trusted that Ireland would not be behind-hand in recognising the claims to a similar honour of such leaders in Dublin as Sir George Porter, Bart., and Sir John Banks, K.C.B. "I fear I have wearied you with topics which at present do not interest you as much as they will later on. Those among my junior hearers I may divide into three classes: (1) The first year's students or beginners; (2) those who are in the middle of their course; (3) those just qualified. Now, I would wish to address a few words to each class. As regards the proper and most advisable mode for a medical student to begin the study of his profession, I am convinced that the system of apprenticeship to a hospital surgeon offers the most advantages. It may be the young fellow just out of school is steady, perhaps does not require to be strictly looked after, yet he must always want advice as to how to prosecute his different studies, and in his master he has a friend, counsellor and guide as a matter of right. On the other hand, if the student is inclined to be giddy, the consciousness of a watchful eye over him in the city may be the means of regulating his conduct and frequently act as a salutary deterrent from evil paths. It is cheaper as regards cost, for in the long run the master, out of the nominal fee he receives, undertakes the entire management of the pupil's studies from beginning to end and pays for all lectures, private teaching, grinding, as well as the three separate diplomas necessary to practise. In this way the pupil is saved a lot of inconvenience and the parent has a responsible person to apply to when he wishes to know how the pupil is proceeding with his studies. As regards the course I would recommend the first year's man to adopt in commencing his studies, I would say—be extremely punctual in attendance at the hospital, try to be in time, even though the morning is wet and cold; do not let little discomforts be pleaded as an excuse for your non-attendance; if your teachers are able to be present for your convenience at an early hour, surely you ought to be there to meet them; and as beginners, I warn you not to be giving up your whole time in looking at abstruse and uncommon cases, which you will not comprehend, instead of learning to dress a cut or adjust a bandage. You must educate your minds by degrees; first grasp the elementary principles of your profession, and by this means you will lay the foundation of a sound practical knowledge of the noble science you are now entering upon."

The lecturer exhorted his hearers to endeavour to realise the greatness of their trust and the responsibility and glory of their almost Divine mission. "Remember at all times that every phase of your conduct, every word you utter, every look, every nod of your head, quiver of your lips, glance of your eye and shrug of your shoulders will be observed and considered, and may inspire hope or despair in an anxious heart. Therefore, strive to make your manner and your methods as faultless as possible. Keep your lamps trimmed and your oil ready, and observe punctuality and system in attending all who place themselves under your care, and strive to do the greatest absolute good for each and every one of your patients, that you may deserve to be called 'a model physician.'"

**THE CONDITION OF THE THAMES.**—The Main Drainage Committee of the London County Council has reported that the River Thames has been in a most satisfactory condition during the past summer. At no time has it been possible to detect the slightest discolouration of the water by sewage matters or black mud, and the foreshores at all points have been clean. The aeration of the water has shown a marked increase, the quantity of oxygen dissolved in the water being on one occasion, Aug. 31st, the maximum quantity possible. This satisfactory result is attributed to the operations at the Council's sewage precipitation works.

#### MANCHESTER ROYAL INFIRMARY.

A CASE ILLUSTRATING THE TREATMENT OF FÆCAL FISTULÆ AFTER TYPHILITIS.

(Under the care of Mr. F. A. SOUTHAM.)

THE presence of a fæcal fistula after the evacuation of a perityphlitic abscess is a complication which fortunately is not of very common occurrence; for, as Mr. Treves has pointed out, if fæcal matter is mixed with the discharge, it usually indicates a direct opening into the cæcum.<sup>1</sup> It is now a well-established fact that in most abscesses of this nature the vermiform appendix—and not the cæcum—is the part primarily affected, an appendicitis being excited usually as the result of the irritation caused by the presence of a fæcal concretion or foreign body in the process. If, as frequently happens, the inflammation runs on to perforation or sloughing of the appendix, and suppuration takes place around it, the pus, though it often has an offensive odour, is not usually mixed with fæcal matter, for the communication with the bowel becomes obliterated, probably at an early stage in the course of the disease.

In the case recorded below, where a fæcal fistula followed the evacuation of a perityphlitic abscess, the appendix was found to be in a healthy condition, the communication with the bowel being situated just at the point of junction of the ileum with the cæcum. Fæcal fistulæ originating in this way generally close of themselves if the patient's diet and the state of the bowels are carefully regulated, no special treatment being required beyond attention to cleanliness and the ordinary means for preventing any retention of the discharge. In a case of this kind recently under the care of Mr. Southam the fæcal discharge, after persisting for about two months, gradually ceased and the fistula then healed. Occasionally, however, in spite of the most careful treatment, healing does not take place and the fistula remains permanently open—a continual source of annoyance to the patient, whose health is very liable sooner or later to become affected by the constant discharge. This result was illustrated in another case of typhilitic abscess which also came under Mr. Southam's observation, the fistula never closing and the patient being troubled with a fæcal discharge until his death, which occurred some seven or eight years after the abscess was opened. The surgical treatment of these cases, when spontaneous closure does not occur, is usually unsatisfactory. Mr. Treves says: "Cæcal fistulæ are very difficult to deal with by operation, no matter at what stage the attempt at closure is undertaken." The operations usually performed in a case of fæcal fistula, in whatever way it originates, are either paring the edges and suture of the opening in the bowel or resection of the intestine. The former method often fails and is as a rule not easy of accomplishment, for the margins of the perforation after a time become thickened and indurated, the bowel itself being surrounded and bound down by adhesions, and often lying at some distance from the surface. Resection of the intestine is a proceeding which is hardly practicable when the cæcum is the part involved; moreover, it is a tedious and a difficult operation, and one which is not only frequently unsuccessful, but is also attended by a high rate of mortality. The operation of "lateral anastomosis" recently introduced by Senn is a method of treatment which appears to be peculiarly applicable to cases of this nature, for by establishing a fistulous communication between coils of intestine above and below the seat of perforation the passage of the fæces can be diverted; and the fistula, being no longer irritated by the escape of fæcal matter, is therefore placed in a more favourable condition for healing. An advantage of this method is that we are enabled to operate upon the bowel at some distance from the seat of disease, where it is free from

<sup>1</sup> The Surgical Treatment of Typhilitis, p. 46.

adhesions and where its walls are in a perfectly healthy condition. It was for these reasons that the operation of lateral anastomosis (in this instance ileo-colostomy) was performed in the following case, where a faecal fistula had been present for some months, as it showed no signs of closing, and the constant discharge was beginning to undermine the patient's health.

A. T—, a male aged nineteen years, was admitted into the Manchester Royal Infirmary on April 9th, 1892, suffering from a faecal fistula, the orifice of which was situated in the right groin about an inch above the centre of Poupart's ligament. About six months previously an abscess had formed in this situation, which from the history appeared to have originated around either the caecum or vermiform process, for its formation had been preceded by the ordinary symptoms of perityphlitis. The patient was extremely emaciated, having rapidly lost flesh during the last few months. The bowels were very constipated, not being moved except by enemata. A few days after admission the opening of the fistula was slightly enlarged, and its tract, which extended backwards for several inches and was very tortuous, was scraped with a Volkmann's spoon. This proceeding was not, however, followed by any improvement, the discharge of pus and faecal matter still being so copious that it soaked through the dressings, which had to be changed several times daily. For the reasons given above it was therefore resolved to perform the operation of ileo-colostomy. In order that the intestine might be as empty as possible the patient was fed with nutrient enemata for forty-eight hours previously to operation, nothing being given by the mouth except a small quantity of milk.

On May 19th the operation was performed, Mr. J. W. Smith, resident surgical officer, assisting Mr. Southam. An incision about five inches long, its centre corresponding with the orifice of the fistula, was made above and parallel with Poupart's ligament. The abdominal muscles and peritoneum having been divided to the same extent, the fistula was followed through a quantity of soft granulation tissue to its communication with the bowel—an opening the size of a shilling, with indurated irregular margins, situated exactly at the junction of the ileum with the caecum on its anterior aspect. The caecum and termination of the ileum were firmly bound down with adhesions, and there were a few adhesions round the vermiform process, which otherwise presented a perfectly healthy appearance. A loop of ileum a few inches above the point of perforation, and where the bowel was free from adhesions, was emptied of its contents and gently drawn out of the wound; a loop of the transverse colon, which lay in close proximity to the caecum, was treated in the same way. Openings were then made in the adjacent loops of ileum and transverse colon and two of Senn's decalcified bone-plates were introduced and secured in the usual manner, care being taken to prevent any escape of faecal matter into the abdominal cavity. No attempt was made to close the perforation in the bowel. The coils of intestine were then replaced and the wound in the abdominal walls was closed with sutures, a drainage-tube being inserted at its centre.

As regards the after-course of the case, there was no diminution in the amount of faecal discharge from the wound during the first week after the operation. On the tenth day the bowels were moved for the first time, and after this date the discharge rapidly diminished. After the fourteenth day the discharge was very slight, containing only a trace of faecal matter, and the wound healed very rapidly. At the end of the third week the patient was up in the ward, the wound being quite superficial, and at the end of a month it was completely healed. The patient left the hospital six weeks after the operation, the seat of the fistula being marked by a firm cicatrix; the bowels were moved regularly once a day and he was rapidly gaining flesh. When last seen, about two months subsequently, he was in the enjoyment of excellent health.

## BRISTOL GENERAL HOSPITAL.

### TWO CASES OF ABDOMINAL SECTION.

(Under the care of Mr. NELSON C. DOBSON.)

THE following case is one of some rarity, and the record of it is important. The general characters of the disease resemble in many respects those of sarcomata of the ovaries, but the clinical cause of the disease after operation is very

different. Dr. Lomer has described<sup>1</sup> an almost exactly similar case, in which the peritoneum was also extensively infected, and his patient survived four years and a half without any relapse. Cases of this disease have also been described by Thornton, Leopold, Cohen, and Freund. In this patient the larger growths, as well as the smaller, were of a papillomatous nature, and resembled the growths found in cysts arising in the hilum of the ovary or broad ligament in connexion with remains of the Wolfian body. They were whitish-yellow in colour, friable and not very vascular. The cysts in connexion with them were each of about the size of a walnut and contained a yellow mucoid fluid and abundant intracystic papillary growths exactly resembling the large extracystic masses with which they were associated. In all probability these were also originally contained within a cyst which had ruptured posteriorly, possibly at the time when the abdomen began to diminish in size in July. The very vascular tissue cut through in cutting into the abdominal cavity was probably the adherent anterior wall of the cyst, the intestines being visible through the ruptured posterior wall. Microscopic examination showed the typical structure of papilloma, covered with columnar epithelium. Papillomatous growths on the ovaries are very rare and are not associated usually with cysts, as they were in this case. Moreover, the ovaries were not recognised in the operation. We are indebted for the notes of these cases to Mr. Charles A. Morton, registrar.

CASE 1. *Ruptured papillomatous ovarian cyst, with dissemination of papillomatous growths over the peritoneum. Laparotomy; recovery.*—A. B—, aged nineteen, began to suffer from pain in the lower abdomen in January, 1891, and the abdomen began to swell. The pain and swelling prevented her getting about, and she was in bed all the early spring and summer. Towards the end of July the swelling gradually but considerably diminished, so that she measured seven inches less than she had done some time previously. She was then able to be up again for about three weeks, but at the end of that time the swelling had again increased, and she was obliged to return to bed. On admission on Sept. 16th there were signs of free fluid in the abdomen, which measured forty-three inches and a half around at the umbilicus. Eighteen pints of watery fluid, deeply tinged with blood, were drawn off. Under the microscope numerous red corpuscles were seen in the fluid. Nothing definite could be felt in the abdomen.

On Sept. 26th Mr. Dobson, with antiseptic precautions, made a small incision in the linea alba about midway between the umbilicus and pubes. The tissue divided just before the peritoneal cavity was opened contained large veins, and after it was opened a large quantity of blood-stained fluid escaped, but no intestine presented at the wound. On passing the fingers down into the pelvis cauliflower-like growths could be felt. The wound was then enlarged so as to bring these masses into view and facilitate their removal. One the size of an orange was removed from the right side and attached to it was a cyst the size of a walnut. It had a distinct pedicle which seemed to come from the right side of the uterus. On the left side was a similar cauliflower-like growth, but slightly larger, and attached to it were several small cysts. It seemed to be attached to the left side of the uterus, and on its pedicle were some smaller papillomatous growths. It was very difficult to tie the pedicle so as to include all these growths. Both pedicles were transfixed and tied with strong carbolised silk. Several small papillomatous growths were attached to the peritoneum in the pelvis. These were swept off with the finger without ligature. The intestines were tied down by adhesions. The abdominal cavity was washed out with boric acid solution and a glass drainage-tube left in.

Two days after the operation the drainage-tube was removed, and on Oct. 3rd the wound was healed and the stitches removed. There had only been occasional pain in the abdomen after the operation, and the temperature was only once raised to 100°. In the afternoon of the 4th marked abdominal pain set in, and the temperature went up to 102° by the evening. On the 5th and 6th the pain continued and the abdomen began to swell, but there was no vomiting, and the bowels were opened. The temperature kept up at 102° at night and was not much lower in the morning. On the evening of the 6th Mr. Dobson again explored the abdomen through the old wound and found the intestines very sticky and matted together. There was not much fluid, but a drainage-tube was left in. The abdominal pain continued, and the temperature kept up until the 15th, when the

<sup>1</sup> *Sejous*, vol. II. 1891. G. 45.

pain was less marked and the drainage-tube was removed. By the 19th the patient was much better. Her condition rapidly improved after this, and she was discharged without any recurrence of the ascites at the end of November. The small sinus (where the tube had been) closed soon after, and now (Sept. 1892) she remains in good health.

Looking at the fact that the papillomatous growths were already beginning to infect the peritoneum at the time of the operation, it is interesting that there has been no evidence of the continuance of the disease.

The subject of suppuration in the abdominal cavity is always an interesting one, and it is frequently extremely difficult, if not impossible, to give the cause of such disease. In the following case the symptoms preceding the appearance of any swelling and the result of the pelvic examination seem to point to pelvic peritonitis as its cause, but the swelling reached much higher than those of this nature usually do. On the other hand, if there had been suppuration in an ovarian cyst there would have been a swelling preceding the symptoms. The facts that there were swelling and drawing up of the left lower limb and the pelvic thickening and possibility of feeling the cystic swelling from the rectum are in favour of the pelvic origin of the peritonitis. But whatever its origin, the woman's condition on admission was a very serious one and the beneficial effects of antiseptic drainage were rapid and marked.

CASE 2. *Large encysted collection of pus in the abdomen; drainage; recovery.*—M. J.—, aged thirty-four, was admitted into the Bristol General Hospital on April 11th, 1892, with the following history. She was the mother of eight children; the last was five months old. The labour had been quite a natural one. She did not suckle the child after the first ten days, and she menstruated naturally a month after her confinement. She was getting about quite well in health until ten weeks before admission—i.e., for two months and a half after her confinement—when severe pain in the abdomen came on, with vomiting and diarrhoea. The diarrhoea only lasted a few hours, but the vomiting continued for three days, and the pain (which was all over the stomach) lasted for ten days. The abdomen began to swell a fortnight after the pain ceased, and then the left lower limb became much swollen and was drawn up, but this condition of the limb passed off in a few weeks. The abdomen, however, steadily enlarged, and there was pain over the right side when she sat up. There had been no dysuria or difficulty with the bowels after the attack of abdominal pain, though dysuria was present at that time. After the first menstrual time, a month after her confinement, she did not menstruate again until two days after the onset of the abdominal pain and vomiting—i.e., a fortnight later. It was then like a natural period, but perhaps rather scanty, and lasted a week. She was an anæmic, emaciated woman. She had always been anæmic, but had lost flesh since the abdominal attack. The right side of the abdomen was greatly distended by a round swelling, which, although it just crossed the middle line, was nearly wholly confined to the right side. It was distinctly round and was very tense—too tense to get fluctuation by percussion, but fluctuation could be felt by bi-manual pressure. It was dull, and not markedly tender. It reached the costal margin above at its lower part, but did not pass underneath it; below it came to the anterior superior spine. To the outer side its edge could not be defined. It crossed the middle line for about two inches, and one could just get between it and the symphysis pubis. There was very distinct resonance in the flank on the same side. No impulse was communicated to it from the renal region. It was very fixed, so that rolling the patient over on the other side did not alter its position. There were irregular rises of temperature after admission, but not to any height.

Dr. Aust Lawrence examined the woman and found the pelvic roof much thickened by inflammatory exudation which fixed the uterus. Per rectum a swelling could be felt extending into the left side of the pelvis. The urine was clear and free from albumen.

April 14th.—Mr. Dobson made an incision in the linea alba just below the umbilicus, with antiseptic precautions, and dissected through the layers of tissue until the encysted collection of fluid was opened; the peritoneum was so adherent it could not be recognised. Several pints of pus were evacuated and a large rubber drainage-tube was put in. The patient progressed very well after the operation. There was very free discharge of pus for some days, but the drainage-tube was removed by the 22nd, as the discharge was then diminishing. She gained flesh and her general health rapidly improved, and she was

discharged on May 15th with only a small sinus. She writes now (Sept. 1892): "The wound was quite healed within a week from the time I left the hospital, and I have been very well in myself since."

## Reviews and Notices of Books.

*Pptomaines, Leucomaines and Bacterial Proteids; or, the Chemical Factors in the Causation of Disease.* By VICTOR C. VAUGHAN, Ph.D., M.D., and FREDERICK G. NOVY, Sc.D., M.D. Second Edition, revised and enlarged. Philadelphia: Lea Brothers and Co. 1891.

No more convincing proof of the important part that pptomaines, leucomaines and bacterial proteids play in our latter-day pathology can be given than a comparison of the second edition of Vaughan and Novy's work on this subject with their first issue. In it the old matter has been corrected up to date, whilst a very large amount of new matter has been added. This is especially noticeable in the chapters on the relation of bacterial poisons to infectious diseases, on the germioid proteids of the blood, and on the nature of immunity-giving substances. The chapters on the chemistry of pptomaines and leucomaines are very much extended, whilst considerable interest will be aroused by the chapter on auto-genous diseases. The tables for laboratory use have been considerably enlarged and increased in number. Although it is impossible to agree with the authors on some points brought forward and discussed, it cannot but be felt, on careful perusal of the work, that it is the result not only of a most careful and discriminating analysis, but of very great labour and anxious thought; and we must again take the opportunity of congratulating the authors on having produced such an interesting work and readers on having such a book at their command.

*The Geographical Distribution of Disease in Great Britain.*

Part I.: Cumberland, Westmoreland and the Lake District; their Climatology, Geology and Disease Distribution. By ALFRED HAVILAND, M.R.C.S. London: Swan Sonnenschein and Co. 1892.

THIS second edition of Mr. Haviland's treatise is virtually a new work. It is the first instalment of what is intended to be a complete exposition of the geographical pathology of the British islands, and Part I. is to be followed by Part II., dealing with the Basin of the Thames. The writer selects cancer, heart disease and phthisis as illustrations of disease distribution in the British Islands. As regards the first-mentioned disease, the author's conclusions are that "the prevalence of cancer in the Cumbrian areas, as throughout Great Britain, is associated with lowness of area, consisting of more or less retentive soils, overlying clayey rocks and subject to seasonal river floods, that bring down from cultivated and uncultivated land and inhabited localities much refuse, made up of vegetable and animal matter, which ultimately is subject to decomposition, which soils are formed that microphytes and other minute organisms rejoice in as conducive to their culture and propagation." As regards phthisis, he finds that the exposed and windy portions of the area under consideration show the largest percentage of mortality from the disease, and goes on to argue that the probable explanation is "that the irritating qualities of the strong atmospheric currents, more or less ozoniferous, produce pulmonary catarrh, and thus, in the untainted but susceptible, prepare the lung for the bacillus, and in the tainted expedite the process of destruction." We must demur both to these alleged facts and to the conclusions founded upon them. So far from it being the case that windy maritime localities are peculiarly prone to breed phthisis, we believe there is trustworthy evidence to

prove that the very opposite statement is much nearer the truth. The wind-swept Hebrides and Faroë Islands present one of the lowest rates of mortality from phthisis to be observed anywhere. The explanation is probably to be found in the habits of the people. Mr. Haviland's idea that "forcible winds spread havoc among the consumptive" is, we think, an error. No doubt for patients with active disease to expose themselves to trying winds such as the mistral or tramontana is likely to be injurious, but wholesome sea breezes will, on the whole, do phthisical patients much more good than harm. As regards heart disease the author finds that the sheltered districts show the highest mortality. This is not *a priori* unlikely, but we do not think that the mere question of shelter or exposure is the sole, or even the chief, factor in the complicated etiology of heart disease. The relations of this disease to rheumatism, extremely important as they are, do not exhaust the question of its etiology, and even as regards rheumatism, exposure to, or shelter from, winds is certainly not the most important point.

To review fully the work before us would require more space than we can afford. It contains much statistical information and several interesting maps. We cannot say, however, that the facts are always well marshalled or that the conclusions are drawn with sufficient precision or philosophical caution.

*Crime and its Causes.* By WILLIAM DOUGLAS MORRISON, of H.M. Prison, Wandsworth. London: Swan Sonnenschein and Co. 1891.

THOUGH we are accustomed to regard crime as a moral plague inherent in man from the earliest recorded ages, it is certainly disheartening to learn that its amount, as indicated by the number of convictions, is steadily increasing, while it shows no real diminution in seriousness. This, at all events, is the view taken by the author of the volume before us, and it is based upon extensive inquiry and statistical data. We should therefore be the more disposed to follow with interest his careful observations upon this wide field of social pathology. As might be expected, particular attention is given to the causes apparently conducive to crime. Some of these, as climate and temperature, are natural, though not therefore uncontrollable. The rule appears to be that the hotter the climate and the more liable to variation the greater the degree of moral instability. Mr. Morrison is not one of those who regard poverty as a powerful stimulus to wrongdoing. Indolence, he says, doubtless truly, has more to do with the matter. Sex and age have some influence also, woman being prone to offend later in life, and less frequently, but in a more inveterate manner than men. As to age, the years between sixteen and forty are said to be the most lawless. A chapter on the physical and mental characters of criminals is interesting, and tends to show that no such thing exists as a criminal type of man, though evil-doing is very commonly a graft on physical degeneracy. As regards punishment, the system preferred is one which is fully punitive and deterrent, but at the same time educative. A timely word in favour of Prisoners' Aid Societies forms a fitting close to this carefully thought-out and instructive work.

*Archives des Sciences Biologiques, publiées par l'Institut Impérial de Médecine Expérimentale à St. Pétersbourg.* Tome I., No. 3.

MME. N. O. SIEBER-SCHOUMOFF contributes to this number of the "Archives des Sciences Biologiques" an interesting article, "Recherches sur les Streptococcus Pathogènes," in which the question of the identity or specificity of the streptococcus of erysipelas, the streptococcus pyogenes and the streptococcus of scarlet fever is dealt with. The writer comes to the conclusion that the streptococcus pyogenes and the streptococcus of erysipelas are very closely

related, although their chemical products differ slightly. The streptococcus pyogenes forms with various soluble sugars—grape sugar, milk sugar &c.—a variable quantity of optically inactive lactic acid, the zinc salt of which contains three molecules of water of crystallisation. The streptococcus of erysipelas produces active light rotating lactic acid, of which, however, the zinc salt contains only two molecules of water of crystallisation; this acid polarises to the left. Otherwise both these organisms are facultative anaerobes; they decompose sugar both in bouillon and peptone solution, and they produce carbonic acid, but no marsh gas or hydrogen. In bouillon without sugar they produce volatile, fatty acids, and substances giving rise to iodoform in small quantities, but they do not decompose fatty matter or salol into their constituent parts. In ordinary meat bouillon or in bouillon containing sugar of milk they form a toxic albumose, that of the streptococcus pyogenes being the more toxic of the two. The streptococcus of scarlet fever, like the streptococcus of erysipelas, decomposes sugar and forms active lactic acid; like the others, it also gives rise to carbonic acid, but in addition, hydrogen is formed. It may be readily distinguished from the other two organisms by the fact that it brings about rapidly and readily the decomposition of salol. A fourth streptococcus is also mentioned, which, however, may be distinguished morphologically from the others; this also forms, from grape or milk sugar or from glycerine, carbonic acid and optically active lactic acid. This organism was found in cases of sporadic mammitis in cows.

*Transactions of the American Climatological Association, Eighth Meeting.* Philadelphia: W. B. Saunders. 1892.

THIS volume contains the presidential address of Dr. Fredk. Knight; and papers on Whooping-cough, by Dr. Musser; on Pleurisy, by Dr. Garland; on Consumption, by Dr. Thurley, Dr. Loomis, Dr. Fisk, Dr. H. F. Williams, Dr. Tynedale, Dr. Fremont Smith and Dr. Glasgow; on Influenza, by Dr. Curtin, Dr. Watson, Dr. Ingals, Dr. Munro, Dr. Mulhall, Dr. A. A. Smith, Dr. R. J. Nunn; and on various Sanatoria, by Dr. Bibber, Dr. C. C. Ransom, Dr. Darlington and Dr. H. B. Moore. The president's address deals chiefly with the desiderata of a good sanatorium as regards hotels, food-supply &c. Many of the questions in the above list are ably handled and the papers and discussions will repay perusal.

**BEQUESTS AND DONATIONS TO HOSPITALS.**—The late Mr. W. H. Rawson of Mill House, Sowerby, Halifax, bequeathed £500 to the Halifax Infirmary, and £100 each to the Royal Albert Hospital and the Royal Hospital for Incurables at Putney. The executor of the late Mrs. E. Holm has forwarded a cheque for £2500 to the Royal Hospital for Children and Women, Waterloo Bridge-road. Miss Zoe Hawke of Lapford House, New Barnet, has given £200 to the Barnet Cottage Hospital. Miss Eleanor Robson of Rye Hill, Newcastle, has sent a donation of £100 to the Northumberland, Durham and Newcastle Infirmary for Diseases of the Eye, Newcastle. The late Lord Winmarleigh bequeathed £500 to the Warrington Infirmary. Mr. Richard Turton, late of Beechenhurst, Selby Park, Warwickshire, bequeathed £500 each to the General Hospital and the Queen's Hospital, Birmingham; £250 each to the Free Hospital for the Relief of Sick Children and the Royal Orthopædic and Spinal Hospital; £100 each to the Ear and Throat Hospital, the Eye Hospital and the Skin and Lock Hospital, Birmingham. A legacy of £100 has been received by the treasurer of the Hospital for Diseases of the Skin, New Bridge-street, London, under the will of the late Mr. H. Vigne of Woodford. The sum of £141 8s. 8d. has been handed to the committee of the Victoria Hospital for Children, being the result of the recent trades' friendly and temperance societies' demonstration. The late Mr. Edwin Smallwood of Redditch bequeathed £1000 each to the General Hospital and Queen's Hospital, Birmingham, and £5000 in trust for endowing a cottage hospital at Redditch, to be called the Smallwood Hospital.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 8, 1892.

THERE is no falling off in the quality of the introductory addresses which we publish this year, and we can imagine no better employment, or one more agreeable to the student, at a time when he has not settled down to the actual tussle with the hard subjects of the curriculum, than to read the whole of them. While his new surroundings are still rather dull and dingy compared with home, and while fellow students are new and strange, the perusal of these addresses will be an occupation that will give dignity and inspiration to the work of medical education. Occasionally the giver of the address forgets the "high calling," and condescends to suggestions or considerations which do not seem equal to the occasion; but taking the addresses as a whole they justify our advice to students to make the perusal of them the first work of the session. And it is not only students that will profit by this proceeding, but teachers and examiners also. We sometimes think that it would not be a bad change for once in a way if, *vice versa*, the introductory lectures could be addressed to them rather than to the students.

The address of Sir GEORGE HUMPHRY to the Birmingham School, which we published last week, for example, contained some truths which, it seems to us, need to be much impressed on examiners and teachers. We refer to his description of the weary weight of ever-multiplying and more exacting examinations, and to the need for some limitation of the area of subjects which the poor student is expected to know something of, but which are illimitable in their detail. His description of the difference between the demand now made of students at examinations and that made of them when he passed the great portal of Lincoln's-inn should be taken to heart by those who pile subject upon subject in the curriculum and exact even more detail in examinations. He well and eloquently says that the cloud of prospective examinations, which in his days was no bigger than a man's hand, "has now spread over the horizon and almost threatens to deluge the scene and drown the whole joyousness of study." At another point Sir G. HUMPHRY, alluding to the need for limitation of detail in teaching and examining, says: "I feel with regard to certain subjects that they had better be left out of the programme altogether than that the student should be *overladen and wearied and his spirit broken by the multitude of facts and details* that are required to be got up." These are weighty words, which the wisest men in the profession will endorse. Indeed, Dr. COUPLAND, a physician and teacher of great experience, has the same account to give of our examinations—"those examinations which loom so fearfully in the distance." Sir G. HUMPHRY has done many good services to the profession and to education. He cannot do anything better than to press these thoughts of his on over-examining and over-cramming into the minds, not so much of students, who are the sufferers, and the grievous sufferers, from the present state of things, but into the minds of examiners and teachers, who are apt to think that students

were made to be examined and even rejected once or twice, instead of realising that examiners and teachers were made to coöperate justly and proportionately in perfecting medical education, in making it reasonable, and, to use Sir G. HUMPHRY's happy expression, "joyous." Students, no doubt, are often to blame; there is a great deal of bad studying from want of attention and love of idleness or pleasure; but there is also much need for better teaching and for a more just and less terrible system of examinations, that are sometimes a terror not only to idle men, but to the best men in the schools.

We cannot profess to go into detail in our comments on the various addresses. We expect students to read them. They give a good view of the many-sided profession on which they are entering—a profession that is still imperfectly recognised and rewarded by the State, but that is none the less one which is felt to be more and more sound in its basis, honourable in its objects and interesting in its practice. The address of Mr. MITCHELL BANKS will give the student some insight into the thoughts of men of former times and of the present day about the great medical profession. He has evidently a keen eye for all that is instructive in art and literature, even where these bear hardly and uncomplimentarily on his own profession. Perhaps he is a little one-sided in the quotations from which he would have us judge of the medical men of former generations and the estimate in which they were held. If so, he makes amends by his acknowledgment of the change in medical men themselves and in the appreciation of them by the public. We may, however, be allowed to express our strong conviction that the *morale* of the old practitioners was not so low and selfish and ignorant as the satirists would have us believe. Be that as it may, we live in a different atmosphere from theirs and have to be judged by different standards. We have knowledge and means of obtaining knowledge altogether different from those which they enjoyed, and we have to deal with a public intelligence of a different nature, though still very defective in regard to medical matters. We have alluded to grave words spoken by Sir G. HUMPHRY which throw, we think, a great responsibility on teachers and examiners. We shall conclude with a few words to students. Mr. BANKS well says that in a new but near century the medical students of to-day will be the representatives of medicine and will have to transmit and to enlarge the knowledge which they are about to receive. They will be without excuse if they do not do well. The preliminary study of physics which was so commended by Dr. BOWLES, and which is one great point of improvement in present medical education, will greatly facilitate their study of physiology and even of medicine. The study of biology in all its forms and branches will enlarge their conceptions of man, while it will show his vulnerability to organisms infinitely little known and till lately quite unknown. And in the study of actual disease they will encounter a problem which will move all that is best and kindest in them. Their success will mean pleasure to themselves, the diminution of suffering to their fellow-creatures and the advancement of a profession which with the growth of its own knowledge grows more and more in its own humility and in the respect of men.

No department of medical education is more important than clinical teaching. To it all other branches of training

are preliminary and subsidiary, and from its character the average practitioner draws most of the principles and inspirations that henceforth direct the practical work of his life. We propose to take a brief glance at the various methods of clinical teaching now in vogue in the chief British and Continental medical schools, and we do so recognising that each of these methods has its special advantage and its special adaptability to some types and grades of students or practitioners. Further, each of the methods presently to be enumerated is capable of being thoroughly effective in the hands of an able and experienced teacher, while none of them affords any guarantee of success in the absence of such qualities.

Let us look first at the method which is the favourite one with such men as HUGHLINGS JACKSON, NOTHNAGEL, CHARCOT and others. We mean the selection of a few typical and cognate cases of disease and the exhaustive demonstration of their symptomatology in the presence of a large class. This method is hardly practicable in the wards of a hospital, but can be readily managed in the hospital theatre or other room specially devoted to such purposes. It is certainly one of the most perfect of methods, serving to set forth in the most vivid and striking way the leading features, types and stages of the disease under consideration. The great vice of text-book descriptions is that the author, from considerations of brevity and convenience, is compelled to describe "typical cases," which are really the exception rather than the rule in actual practice. He often writes having before him a vivid picture of a disease in its most marked and accentuated form, but for one such case the student finds ten with all sorts of *nuances* of differentiation. The method of clinical teaching which we are now considering is well adapted to correct such misconceptions. When practicable the cases selected should include "type cases" by all means—they afford at least a standard for comparison,—but also cases presenting as far as possible the various stages of differentiation from that type. An ideal clinique, for which the materials even in a large hospital are not always available, would include the demonstration of two or more "typical" cases, then of several cases closely analogous to these, and lastly of examples of the disease in its most obscure and aberrant forms. It is too much to hope that such a selection could be generally available, but this is at least the standard to be kept in view.

The foregoing method, while possessing enormous and perhaps pre-eminent advantages, has also certain drawbacks. Unless corrected and supplemented by the other methods to be presently alluded to, it would tend to reduce the labour of observation to a minimum and to make the student too much inclined simply to receive without examination the *ex cathedra* statements of his teacher. The power of observation could not be cultivated to its highest point by this method alone. The observer must often be left to "break ground" for himself, to feel his way among obscure and perhaps conflicting symptoms, to make mistakes in his observations and to learn some of his best lessons from those mistakes. Further, this "comparative" method of clinical teaching which we are considering implies that the student has at least enough knowledge of his subject to understand a comparison and to check the information given to him by referring it to facts already acquired. Hence the method is perhaps not very

well adapted to beginners. It is, however, *par excellence*, the method for the advanced student. He may safely be assumed to know ordinary diseases in their general forms, and to be solicitous to observe rather the rarer features of disease and its most exceptional varieties. For this purpose no method will compare with that in which comparison and contrast play the chief parts.

A second method has been always a favourite with many of the best teachers, especially if endowed with unusual gifts of eloquent and picturesque demonstration. Sir ANDREW CLARK'S clinical lectures in the wards of the London Hospital are among the best examples of this method which the present generation has seen. We mean the selection of one well-marked "type case" of disease and the exhaustive demonstration of all its features. In able hands this is a very effective method, especially for the student who is making his first acquaintance with the disease in question. It serves to fix in his mind a vivid picture of a particular malady and ensures that its leading features shall be retained throughout life. Clinical teaching loses much from the want of this power of creating a permanent impression. Most of it is too feeble and too devoid of attraction to be long retained in the mind. It fades away, and the student, looking back on years of perhaps hard and honest work in the wards, is astonished to find how few clinical cases have retained an abiding place in his memory. This second method of clinical instruction is capable of affording the student at least a few striking cases which he can never forget and which afford him examples of how many of his cases should and might be studied. This method, while obviously much inferior to the former one in its capability for enforcing points of contrast and difference, may still be utilised to some extent for this end. A teacher, for example, while demonstrating a case of pleural effusion will take occasion to emphasise the points of contrast with pulmonary consolidation, or if *tuberculosis* be his subject he will naturally contrast it with multiple sclerosis and bulbar paralysis. This is, again, to employ the method of contrast, but in a less effective form than in the case first considered. On the whole, this second method is probably the best of all for a beginner. Until he has acquired a fair grasp of the leading features of a disease in its ordinary form, subtleties of contrast and difference are manifestly beyond him. The student should, however, be carefully warned that typical cases are not the rule in disease and that he must be prepared for many exceptions both as regards the excess and defect of symptoms.

A third method is that in which the clinical teacher assigns a case to a student or group of students, allowing time for examination and diagnosis, and then by questioning elicits the conclusion that has been arrived at. This method has, in the case of the sufficiently advanced student, much to commend it. It is as it were a "natural" method of putting the student as nearly as possible in the position which he will afterwards occupy in actual practice. It throws him upon his own resources, draws out whatever stores of knowledge or experience he may possess, serves often as a reminder of his ignorance, enables him to profit by his mistakes, and is in many other ways salutary. It calls for much tact and patience on the part of the teacher, who must know what to expect from his pupils, help them over

real difficulties, encourage them in the right place; rebuke ignorance and haste when necessary, and hold up a correct ideal of observation and diagnosis. Whatever other plans are employed, this last can never be neglected. All three methods have their place and their utility and no one of them should be regarded as in any way excluding the others.

THE therapeutics of cholera are undoubtedly secondary in importance to the prophylactic measures which guard the individual and the community, but they are none the less worthy of the closest attention of the profession. Letters on the treatment of cholera, or, indeed, of any other disease published in lay papers and addressed to non-professional readers, are open to the gravest objections. One correspondent of a daily paper, writing from Hamburg, deals with the castor-oil treatment, and says that it would not meet with the smallest support on the Continent from men "at handgrips with the cholera." On one point he betrays only a slight acquaintance with the facts. In different parts of his letter he indulges in high eulogy of Sir THOMAS WATSON and his strong condemnation of measures for "carrying off the offending matters" from the intestine, and advises his readers rather "to quiet the irritation and stop the flux as soon as they can."

This was undoubtedly Sir THOMAS WATSON's advice and that of nearly all other practical physicians in Great Britain up to the time (1866) when Dr. (now Sir GEORGE) JOHNSON pressed with so much ability the use of castor oil, which he had employed in 1854. He converted his distinguished leader and teacher Sir THOMAS WATSON, who, with that frankness and honesty of action and of language which make his character and his writings so powerful in the profession, adopted the view of Dr. JOHNSON, that at certain stages of the disease castor oil was to be given in opposition to the then general opinion that all diarrhoeas in a cholera season should be stopped as soon as possible. Sir THOMAS WATSON had no personal experience of this new treatment, and adopted it solely under the spell of his able colleague's influence. Still, Dr. JOHNSON thought much of Sir THOMAS WATSON's conversion and made much of it, and continues to do so. Nor was he the only convert. There are many others, such as Dr. MCCOY, who published in THE LANCET of Aug. 18th, 1866, notes on the treatment of 123 cases of cholera in the Liverpool Parish Infirmary. He gave castor oil for the most part after the stage of collapse had set in, and considered that the eliminative treatment had been most successful. Dr. MACLEAN of Netley (*vide* THE LANCET, Feb. 17th, 1886), though thinking that in this disease there was enough of purging, without calling in the aid of artificial purgatives, spoke respectfully of Dr. GEORGE JOHNSON'S treatment, and said that if again smitten he would rather fall into the hands of a *purging* than of an *astringing* physician. He spoke with the authority of one who had not only seen much of the disease in India, but had gone through it himself and attributed his recovery to a faithful servant, who supplied him with iced soda-water, and later to a judicious medical friend, who, instead of dosing him with much physic, sustained him with suitable food in teaspoonfuls, such as arrowroot, well boiled, flavoured with a bitter aromatic, or a teaspoonful of brandy when it could

be borne; then he gave him milk and lime-water flavoured with curaçoa, advancing to beef-tea &c. as the stomach recovered itself. Nevertheless, the general opinion of the profession and of those who have seen most of the disease has been in accordance with Sir THOMAS WATSON'S first views and against any system of treatment by purgation.

The most general agreement in reference to the treatment of cholera is perhaps in regard to the composition of the blood, to keep it normal as long as possible, and when it has lost its serum to restore the same by convenient drinks and by warm water injections more or less medicated by saline venous injections &c. No one has as yet demonstrated that in the early diarrhoeal stage of the disease a patient is the better for having purgatives systematically administered any more than a patient with typhoid diarrhoea would be the better for similar treatment. On the contrary, experience has seemed to show that by such treatment, gastro-intestinal distress is aggravated, which in cholera cases tends to hasten the collapse of the patient and bring about uræmic complications. Rather it appears that the use of medicines and food which allay irritation and diarrhoea in the early stage are very important. In the selection and use of these there is infinite room for the judgment and experience of the practitioner. As regards treatment of the later and graver stages of the disease, Sir GEORGE JOHNSON has done much good by directing attention to its complicated character and to the harm done by overpowering the patient with opium and stimulants. Our own correspondents report that on the Continent drugs are considered in this condition to be of secondary importance, and that the chances of recovery depend on the use of means by which the lost fluids of the body may be restored and the heat of the body recovered. Our Paris correspondent's account last week (p. 795) of Dr. GAILLARD'S treatment of the algide stage with rubbings, hypodermic injections of caffeine and saline injections of sterilised water with saline ingredients in solution into the saphenous vein, or, where the patient is able to swallow and keep down fluids, the gradual administration by the mouth of a litre of sweetened water containing fifteen grains of lactic acid, would seem to show that these measures have saved many lives. Of 173 cures Dr. GAILLARD attributed twenty-five to the transfusion of sterilised serum. Fifty-two very serious cases "were saved" by the lactic acid treatment only without transfusion. It is evident that the operation of transfusion deserves much attention in view of possible resuscitations of the epidemic. We have already alluded to the rectal injections of warm water, containing benzoate of soda or tannin, used and so strongly recommended early in the disease by Professor CANTANI of Naples. Pending the discovery of more specific remedies, the best hopes of diminishing the fatality of cholera seem to centre in the judicious treatment of preliminary diarrhoea, and for the later stages in the restoration of the lost constituents of the blood. If the administration of castor oil were specially indicated it would be in those comparatively rare cases in which there is choleraic collapse and cramps *without evacuations*, but with evidence of distension of the intestines with fluid. The general opinion seems still to be that purgatives should not be regularly administered in this disease, but reserved for

exceptional cases. The removal of peccant matters is an old and popular theory, but the application of it in grave disease requires much consideration.

THE present month is the one usually chosen as the time for departure by that large and increasing class who for various reasons are compelled to winter abroad. The main idea on their part is to escape the cold and fogs of November, and perhaps hardly enough consideration is given to the conditions of climate which await them in the month of October in the sanatorium they may select. Thus, whilst October is too early for Algeria or Egypt, it is too late for some of the Swiss resorts, and even at some of the most favoured spots on the northern shore of the Mediterranean there are serious drawbacks to this season. In the Riviera, for example, it is one of the wettest—often the wettest—months in the year, and the rains are frequently excessive. As much as ten inches and upwards of rain have been recorded at Mentone during this month, and the torrential character of the rains sometimes puts serious difficulties in the way of locomotion. The traveller seeking health who reaches his winter's rest amidst this autumnal deluge is apt to have his dreams of perpetual sunshine rather rudely dispelled, and as first impressions count for much as regards their moral effect, it is very undesirable that the first acquaintance with a very lovely and charming region should be made at a time when its disadvantages are at a maximum and its good qualities most obscured. Other places might be named at which malaria still lingers during October, and on the whole it must be admitted that, like April, it is a difficult month for which to suggest perfectly unexceptionable resorts. Many travellers might with advantage consider whether they can do much better than spend the month of October somewhere on our own southern coasts. By the last week in October the difficulties of choice to which we have alluded are practically over, as this is not too early to leave for the Riviera, Algeria or Egypt. November opens up the favourable season at each of these resorts, by which time both the summer heat in some cases and the autumnal rains in others are usually sufficiently abated. October is also a favourite month in which to start for the long sea voyage to Australia and New Zealand. Here, again, there is the drawback that the time marked out for departure by the exigencies of the English climate does not fit in very well with the climatic conditions to be expected at the termination of the journey. The traveller who starts for the antipodes in October may expect to arrive either about the beginning of December if he selects a steamer, or about New Year's Day if he voyages by sailing vessel. In either case he arrives at quite the worst season of the year. Many parts of Australia have a most admirable climate for at least eight months in the year, but the summer heats are nearly everywhere excessive, and the frequent dust storms are both very annoying and seriously hurtful, especially to pulmonary cases. If the traveller arrives in Australia about midsummer, two or three courses are open to him. He may try some of the elevated resorts, such as Mount Macedon in Victoria, or Katoomba, Armidale, and Mount Victoria in New South Wales, or he may cross at once to Tasmania, where the summer climate, though hot, is quite tolerable, or he may

proceed to New Zealand. In any case he should make a very brief stay in the large cities or lowlands of Australia.

Opinions differ as to whether October is a good month at which to arrive at Davos and the other elevated Swiss sanatoria. On the one hand, it is urged that there are advantages in the patient becoming habituated to the strain of altitude before encountering the strain of cold, while on the other hand it is disputed whether the full advantages of the high Alpine climate can be enjoyed until the winter snows have definitely set in. There seems little doubt that the transition stage from autumn to winter, like the corresponding period of transition from winter to spring, is one of the least agreeable portions of the year. Davos owes a good deal of its success to the general uniformity of its meteorological conditions during the period of resort thither and to the general acquiescence of patients in the somewhat rigorous rules of life which these conditions demand. Periods of transition raise various debatable points and open the door to many possible indiscretions.

On the whole, our remarks would seem to point to the conclusion that invalids proposing to winter abroad should not unduly precipitate their departure, unless under some special circumstance. The last week in October will often be found about the best time for saying adieu to the shores of Great Britain. While we would thus deprecate a premature departure for winter quarters, we would even more strongly deprecate a premature return. Many resorts, such as Egypt, Algeria and Morocco, become too hot in April, but this season is for most invalids far too early to think of returning to England. April and May are very often among the most trying and treacherous months in the year for many patients. The Riviera is still delightful at this time, or Biarritz might be tried with advantage, or such mild Swiss resorts as Montreux or Vevey. In any case the invalid, if his case be one of real gravity, should not arrive in England before the beginning of June.

Breaking off home ties and starting for foreign and often strange lands are apt to be trying to all, and especially to the invalid. But he has much to compensate him—escape from the sunlessness, the rain, the fog, the depressing gloom of the British winter, and the prospect of some months of residence in beautiful regions, full of natural and historic interest, and warmed and brightened by abundant sunshine. If to these be added the consciousness of renewed vitality and a fair hope of ultimate recovery, the fate of the invalid in his winter quarters need not call for commiseration.

### ONE ASPECT OF THE SCARLET FEVER PREVALENCE.

WITHOUT wishing in any way to detract from the importance of the work which the Metropolitan Asylums Board are carrying out in the isolation of scarlet fever cases, we cannot but feel that the constant announcements which are being made as to the gigantic operations in progress are calculated to mislead the public mind and to convey a wrong impression as to the gravity of the circumstances at present

affecting the metropolis. It is perfectly true that scarlet fever is somewhat widely prevalent, and that great value attaches to the isolation in hospital of all those cases which cannot be properly isolated in their own homes and which would otherwise tend to spread the disease, especially by attendance at elementary and other schools. But, after all, when this prevalence is compared with previous prevalences of scarlet fever in London by means of the only comparison available—namely, the amount of death which it causes—the result is by no means alarming. During the month of July the deaths from scarlet fever in London varied in the four weeks from 2 to 4 above the average for the same weeks for the previous ten years, and in the fifth week they were 2 below the average. During the four registration weeks of July the deaths in three weeks varied between 2 and 11 above the average, and in the fourth week they were 3 below the average; and during September the deaths varied in the first three weeks between 3 and 13 above the average, whereas during the last week they were 2 below the average. Now, when we remember that we are dealing with four millions and a quarter of people there is nothing so very grave in our so-called great epidemic, which is actually detaining people in foreign cities where the risk to life is infinitely greater than in the metropolis. The truth is that were it not that we know, during this mild prevalence of scarlet fever, for the first time how many persons are attacked as well as how many die, and were it not for the efforts made to get everybody into hospital and then to announce the totals, very few people would ever have known that anything unusual was in progress. Notification is of great value; its value has largely to do with the facilities for securing the isolation of those needing removal to hospital; but the two systems of notification and isolation ought not to produce a needless scare.

#### DISEASES AND THEIR TREATMENT.

If we were in search of a title at once comprehensive and concise by which to describe the whole sum and substance of medical practice we could find no fitter phrase than that of "Diseases and their Treatment." The joint endeavours of surgeon and physician have no wider field than this, and within its compass there is more than enough of scope for their combined energies. So great a work implies an equal responsibility. By common consent also it demands for its performance a special training and an intimate knowledge of its subject matter. The state of the human body in health and in disease forms but a part of this. Its counterpart is found in the numerous means available for its relief when needful, but capable if misused of inflicting upon it lasting injury. It would be well if these critical relationships were more clearly recognised than they are by many at the present day. In all times, it is true, empiricism has treated them with reckless levity, and in this respect its character continues unaltered. Latterly, however, it has become wider and somewhat unlooked-for connexions. We find many, for example, of the general public imbued with its mock medical principles, and drugs have but to earn a nominal reputation that they may be used without further precaution than that suggested by the guess therapeutics of these amateur doctors. Perhaps a benevolent laxity of the profession in such matters has done something to maintain this practice of self-treatment. Worse if possible, as offending against a clearer light of knowledge, is the error which has led some chemists of intelligence and reputation to prescribe in illness. We are well aware of the difficulties in which men of this class are often involved on this account by the importunity of customers. We gladly acknowledge also their frequent escape from the snares thus laid for them. All the more, therefore, must it be a matter for regret that in some quarters

there exists a tendency to encourage this unwarranted form of practice. An advertisement has recently announced, for example, among the other attractions of a publication devoted to the interests of druggists, a remarkable treatise on diseases and their treatment by a London physician. We might look far and wide without finding a more evident incitement than this to counter-prescribing. There is clearly an implied fallacy in the introduction of such treatises as this into a druggist's handbook. It is impossible by any such theoretical disquisitions to make a chemist a medical man, and, this being the case, he is practically encouraged by literary efforts like the above to undertake duties of great and critical significance for which he must be unqualified. Most of his class, we trust, will have wisdom enough to disregard the subtle inducement, and, however willing to increase their knowledge of medical generalities, will prefer to seek for custom with repute in the legitimate services of their useful calling. An inquest recently held by Mr. John Troutbeck serves to give point to the above remarks. It transpired that the deceased, a child aged six, had been prescribed for by a chemist. As she got worse, Dr. Edward J. Nix was called in, who found her seriously ill. After death a post-mortem was made, and acute peritonitis was found. The chemist had prescribed aromatic sulphuric acid and tincture of capsicum, which Dr. Nix testified would accelerate the disease. The coroner pointed out the great danger of chemists prescribing, and the foreman of the jury stated that the majority of the jury were of opinion that chemists should not be allowed to prescribe in any case. A little healthy expression of opinion by juries in such cases would do much good.

#### AN IRREGULAR TAX ON MEDICAL PRACTITIONERS.

MEMBERS of the medical profession are, like all other members of society, exposed to the nuisance known as "tipping," which is meekly endured as one which cannot be cured, though they might claim exemption seeing the enormous amount of gratuitous work performed by them. There is, however, one very objectionable form of "tipping" against which a protest must be made. We allude to the practice which prevails more or less generally throughout the country by which medical witnesses are docked of the shilling part of their fees at coroners' inquests, these shillings being supposed to be, by a kind of unwritten law, the perquisites of the "beadle" or "coroner's officer." In one town the shillings are not even tendered to the medical witness, the beadle keeping these as his right. More frequently they are handed up to the witness to be duly handed down again. County coroners generally pay the fees themselves, and in these cases the police officer in charge of the case is often the recipient of the odd shilling or shillings. So far as Middlesex is concerned the custom admits of at least a plausible explanation. Although the coroner is required by a former as well as by the present Act to pay the medical witnesses immediately after the termination of the inquest, this has not always been done, and fees have been allowed to accumulate for some months. They have then been taken by the coroner's officer to the medical witness, who has felt compelled to give him the odd shillings for his trouble. This, to our own knowledge, is what happened many years ago; whether it obtains now or not we do not know, but we hope not. When these fees are paid, as they always ought to be, immediately after the inquest, there can be no reason why the medical witness should not receive the whole of the fee specified by the Act without any deduction whatever either for coroner's officer or police. In all well-regulated police forces the acceptance of any gratuity, except with the express sanction of the head constable or superintendent, is viewed as a gross breach of discipline, and if discovered is punished severely. All

medical witnesses have during their student career and subsequently rendered kind assistance to the police without any hope or expectation of requital, and police officers ought in their turn to be civil and obliging to medical witnesses, in common with all members of the community, without expecting a reward.

#### A BLEND OF CIGAR STUMPS.

A TRICK of trade which owes its recent exposure to the energy of the Inland Revenue officials deserves a passing notice. The manoeuvre in question, though ingenious and even in a sense thrifty, cannot claim the merit of originality, inasmuch as it is modelled on a well-known peculiarity of idle boyhood. It consists in collecting the unused ends of smoked cigars and retailing them as the crumbled body contained within a sound outer leaf of tobacco. We need not dwell upon the rank dishonesty of this proceeding, by which the public and the national revenue are equally injured. Its disgusting uncleanness would shock the least fastidious lover of tobacco, while, on the other hand, it is open to grave objection on the ground of health. The cigar stump, sodden and coated with mucus and saliva, could hardly be relied upon to resist the action of any germs it might harbour, and who can tell what varieties these might not include over and above the ordinary agents of putrefaction? We need not pursue the argument further. The sanitary teaching it implies is obvious.

#### PRACTICAL SANITARY WORK IN BENGAL.

WE are glad to find that at last, according to *The Times* correspondent in India, some practical action is to be taken in the direction of attempting to deal with the disease-causes of Lower Bengal. The Bengal branch of the Indian National Congress has formally represented to Sir Charles Elliott, the Lieutenant-Governor, the all-important questions of sanitation, the supply of pure water and the adoption of an effective drainage system for the province. Large tracts of land have become water-logged and the soil is a damp sponge, impregnated with human and animal impurities. Malarial fever is the scourge of whole districts and the effect on the health of the people is terrible. This is of course no new thing. It has been long known, and Government commissions and committees have reported on it again and again. The evil and the remedies were alike known, but were the people ready and willing to aid in their application and contribute towards it according to the measure of their resources? Sir Charles Elliott grasped the situation long ago, and he has wisely embraced the opportunity which this appeal to him to take in hand a system of drainage for the whole province has offered. He quite agreed that the alleged causes of the evils in question were the real ones, and that they required to be dealt with in the way and on the scale that had been represented. But under what conditions and subject to what limitations is the Bengal Government recommended to enter on so large and costly an enterprise? To test the sincerity of the appeal and the reality of its alleged representative character a mixed committee was appointed, of which the native members formed a large majority, and propositions of a very practical character were submitted to them. The members of the committee accepted the responsibility of their position and have furnished a reply, in which they show that they clearly appreciate the scope and urgency of the problem, about which there can, indeed, be no doubt, and are ready to afford support to the financial and legislative measures necessary for dealing with it. Railway embankments, the silting up of rivers and subsidiary lines of drainage, together with an increasing density of population and other insanitary conditions, have of late aggravated the evils. A Brahmin gentleman, speaking of a district within a few miles of Calcutta which thirty years ago had

a comparative immunity from malarial fever, says that now quinine is almost as much needed by a family as rice. The committee has passed resolutions of a practical character empowering the Government to require municipalities to combine together for the purpose of executing sanitary works in a combined area, and for ascertaining the wishes of the majority of the inhabitants or owners of property in districts where disease is unduly prevalent in regard to any drainage or sanitary scheme considered necessary to deal with it. If the majority, as represented by the district board, supports any such scheme, the Government is empowered to undertake it and to raise the necessary funds from the affected area. We concur with *The Times* correspondent in thinking that the Lieutenant-Governor is to be congratulated on the step he has taken in practical public health legislation and in regarding this experiment of a representative conference, with a large majority of native members, as of special interest at the present time.

#### THE SENSE OF SMELL.

IN a recent number of the *American Journal of Psychology* Professor Jashow communicates the results of observations made on a student twenty-one years of age, who suffered from complete anosmia. An abstract appears in the *Neurologisches Centralblatt*. The patient's mother had had no abnormality of smell until she was thirteen or fourteen, when she had completely lost the sense. In the patient on whom the observations were made the defect was evidently congenital. Taste as well as common and thermal sensibility were undisturbed, and the patient therefore offered a good opportunity for testing the sensations in the mouth and nose, and it might be inferred that differences which he could perceive in savoury substances were perceived not by smell but by some other sense. The interesting investigation showed that the greater number of taste perceptions, as they are commonly understood, are really to be referred to smell. No distinction could be made between tea, coffee, and hot water, so that he took the last named, with sugar and milk, as his ordinary breakfast beverage. He confused bitter almond water and water three times in five trials, while he correctly discriminated ether and water, the former, he said, producing in his throat the sensation of peppermint. With ammonia and ether he was right six times in eight trials; and Professor Jashow ascribes the two errors to fatigue. The various fruit syrups he could not distinguish, merely recognising them as sweet. Mustard produced a sharp sensation on the tongue, but was not recognised any more than pepper, while cloves and cinnamon were distinguished. Differences of one degree of temperature were easily recognised.

#### PROTECTION OF VINEYARDS FROM PHYLLOXERA BY METALLIC SALTS.

SOME interesting particulars in regard to this year's claret vintage in the Medoc district are contained in a letter published in *The Times* of the 29th ult. The report is all the more interesting as it gives some evidence of the progress made in the treatment of vines with a view to their protection from disease. The vineyards of France, it is not surprising to hear, have passed through a severe ordeal this year. In the Medoc district, as in England, bitterly cold weather was experienced on April 19th, and there was a frost such as had not been known since May 6th, 1861, the vineyards inland suffering considerable damage. On this account it was conjectured that many of the large estates would only yield half the quantity of last year's crop. On the other hand, the vines on the more elevated lands, together with those along the river, were preserved, the latter owing, it is presumed, to the water of the Gironde—which at that period of the year would be at about 43° F.—having raised the temperature of the air with which it came in con-

tact. The vineyards at Château Loudenne, which occupy a position along the banks of the river, are expected to produce 800 hogsheds of wine, which will be equal to the yield of 1891. Although the flowering of the vines took place under the most favourable circumstances, the month of August further decreased the prospects of an average yield in many places owing to the exceptional heat which then prevailed. At the Bordeaux Observatory the thermometer registered 108° F. and the grapes were in many places scorched and burnt. In spite of all these trials the quality of the 1892 vintage, it is considered, should be good. Although the crop will only be about one-half of the average yield, the vines are in a healthy condition, and the weather continuing favourable for the ingathering of the grapes, the 1892 wines of the Medoc should possess both body and colour. By care and labour the vineyards have been completely freed from the mildew; and the phylloxera, if not completely exterminated, is at least held in check on all the well-managed vineyards. How the pest has thus been combated is not explained. If, as it is suggested to us, the remedy has consisted in applying a mixture of slaked lime and copper sulphate to the vines, it would be satisfactory to hear from some decisive authority, in view of the extraordinary assimilative powers that plants possess for metallic salts, whether after this treatment any important quantity of metal finds its way into the juice of the grape. At any rate, the recent success that has attended the efforts of those who take part in this most important and interesting industry is a matter for congratulation, and those who drink claret will hail with satisfaction the report that the vintage of '92, like that of '87 and '90, is likely to be productive of a good "full-coloured and fruity wine." The total production of wine over the whole of France in 1891 was 663,000,000 gallons (of which the Gironde department alone produced 54,000,000 gallons), and its value, according to the report of the British Consul at Bordeaux, was no less than £40,600,000.

#### DISEASES AMONGST MULATTOES AND INDIANS.

In the *Boston Medical and Surgical Journal* of Aug. 25th are abstracts of two interesting papers on the above-mentioned subject. The first is by Dr. W. A. Dixon. He comes to the conclusion, from observations extending over a period of more than thirty years, that the offspring of mulattoes are the subjects of constitutional disease to a greater extent than those of unmixed blood, and when confined entirely to their own class—that is, without the admixture of pure negro or white blood—they scarcely ever reach the fourth generation in descent. Tuberculosis exists to an excessive degree among the descendants of mulattoes; they are inferior in vitality, intelligence and morality, and show a high rate of mortality. Dr. Dixon has found it quite noticeable that mulatto girls develop at a younger age than either white or negro girls, and that as women they fade much sooner; also that after the second generation of pure mulatto breeding practically all the children born are females. He remarks that it has already been proved in other races that human hybridity cannot be maintained without reversion or fresh supply from parental blood. He suggests the possibility of the danger that tendencies to tuberculosis and other strumous diseases may be increased in the United States by the large mixture of nationalities which is taking place in it, and points to the immunity enjoyed by the Jews and other unmixed races with regard to these affections. In the second paper referred to Dr. A. B. Holden, in an article on the Sanitary Effects of Civilisation, calls attention to the fact that it is the "transition period" in which the constitution of the Indian suffers. If he could be given at once a knowledge of the laws of health

and then have the best hygienic surroundings, he would undoubtedly be better off than in a state of savagery. "The evils of imperfect civilisation and misapplied efforts at civilisation, however, are serious enough to deserve careful attention." The gradual, though slight, decrease in the numbers of the Dakotas illustrates the truth of this proposition. Living in the tepee or lodge, it was easy to move away from any place as soon as it became too dirty for comfort. But now they remain in their houses in the same place, no matter how filthy the neighbourhood becomes. They have never learnt to cook the new food properly, so that there is much indigestion. When children are brought from camp to the boarding-schools a marked improvement is invariably seen in their condition, while they very often suffer from a return to camp life. Dr. Holden then considers tuberculosis among the Indians. "Consumption" and scrofula were the causes of 900 out of 1453 deaths reported in 1888. The death-rate from phthisis alone is stated by different physicians at from 40 to 75 per cent. "The savage is less liable to become sick or to be injured, but when sick or injured to the same degree is more liable to die than the civilised man." In this respect he resembles the negro. Tuberculosis is found in every Indian tribe. In a few places malaria causes more deaths than phthisis. From statistics gathered from agency physicians it appears that scrofula is often very prevalent where no syphilis can be found, and that scrofula may not be encountered at all in tribes where syphilis is common. In the life of the Indian the sanitary evils are those of dress, dwelling and diet. These evils increase the natural tendency to tuberculosis and serve as exciting causes where such a tendency already exists.

#### THE CROWN REPRESENTATIVE FOR SCOTLAND.

WE do not regret the delay which is taking place in filling the vacancy in the Crown representation for Scotland in the Medical Council. The difficulty of the Government arises partly from the fact that there are so many eligible persons in Scotland for such a post. There are colleagues, in the professoriate, of the late Sir George Macleod whose devotion to medical educational work entitles them to the post and whose voices would command great respect on the Council. On the other hand, the universities and the corporations are already so strongly, and the body of the profession so inadequately, represented that there is much to be said for the nomination of a gentleman not officially connected with either universities or corporations, but representative of the wants, educational and otherwise, of the profession. There is precedent for this in Scotland, whose Crown representative for many years was the late Dr. Fergus, one of the able general practitioners of Glasgow.

#### THE SUPPRESSION OF GLANDERS.

THE Board of Agriculture has at last been moved to do something in preventing the extension and prevalence of glanders by issuing an Amended Order, which is to come into operation on the 17th inst.; but most unfortunately the carrying out of the measures it contains is left to the multitudinous local authorities throughout the infected counties, and their enforcement is permissive, not compulsory. The Board must be perfectly aware of the uselessness of such machinery for this purpose, as it has signally failed in everything it has been called upon to undertake in this direction for a quarter of a century, and will in all probability fail again after making serious inroads upon the finances of the ratepayers. We are pleased to note, however, that the Board has recognised the necessity for treating glanders and farcy as one disease, for they were never anything else, so that the confusion and loss resulting from this error can now be avoided. Animals affected with either may be slaughtered at once, as well as those which are suspected of being

contaminated. Compensation is to be given for such slaughtered horses or mules when diseased to the amount of one half their value; in the case of suspected animals destroyed the full value is to be awarded. Such compensation is likely to prove a great inducement to fraud, and with respect to diseased animals is decidedly unfair to the ratepayer. Suspected stables may be entered and placarded if found to be infected, and power is given in other ways to control the disease; but the task of combating this destructive and dangerous equine scourge should have been undertaken by the central authority. No notice has been taken of the risk of having glandered horses imported from infected countries; in fact, we can only look upon the Order as an attempt to silence the agitation that has been going on for energetic action in dealing with the disease and to evade responsibility and trouble. Such an Order might have been issued any time during the last twenty years, and before the impotency of the local authorities had been so clearly demonstrated.

#### DEATH OF LORD TENNYSON.

At the moment of going to press we learn that Lord Tennyson, enfeebled by years, and after lingering in a condition of extreme weakness, but unruffled by physical pain, has passed away. There is probably no living Englishman whose loss will be more mourned. He has left a gap that cannot be filled, for as a poet he stood far above all his compeers. If he occupied a position beneath some of our country's greatest poets, in power of creation and dramatic force, he was above most of them in grace and delicacy and refinement of expression and diction. There was nothing false or meretricious about his verse. He had the true touch of genius, and, what is a rare gift among versifiers, an evenly balanced mind. Lord Tennyson was always true to himself. He did not seek to lead a forlorn hope of attack against the false aspirations and ideas of his age. His tolerance and charity were broad, his sympathies deep, and a vein of tenderness and reverence ran through all he wrote. He died in the early hours of Thursday morning, after a brief and painless illness.

#### THE IDENTITY OF SYRINGO-MYELITIS AND LEPROSY.

AN important paper was recently read by Dr. Zambaco before the French Académie de Médecine on the identity of syringo-myelitis and leprosy. He had seen in Constantinople a considerable number of lepers, and became gradually convinced that the affection described as Morvan's disease, or syringo-myelitis, was no other than leprosy. He had also carefully studied the subject in Brittany, where syringo-myelitis had been first described, and where later on the disease was reported to occur frequently. He observed in all cases which were detained in hospital as incurable deformity of fingers and various other trophic changes, such as loss of one or more phalanges, muscular atrophy, anaesthesia or ulcerations, and all these symptoms he had previously observed in lepers. Photographs of a large number of these were shown which indicated a great resemblance between the two affections. Names of localities, such as *lambezeller*—i.e., "leper village"—and of cemeteries, bridges &c., which are still called *des lepreux*, testify to the fact that the disease has been endemic in Brittany since the earliest times. Old pictures of saints and fairies represent lepers just as they appear now. In a picture, for instance, of the miracles of St. Vincent, the saint is represented as restoring to a leper child its missing fingers. Dr. Zambaco believes that he is justified in concluding from stones, figures, and other objects found in many graves in Brittany that leprosy was imported into the country by the Phœnicians. He had discussed the subject with many

physicians in various hospitals in Paris also, who fully admitted the resemblance between the affections. A case in Charcot's ward which had been diagnosed as typical syringo-myelitis, and in which several fingers had been painlessly amputated, was brought to the Hôpital St. Louis and introduced to MM. Vidal, Besnier, Fournier and Hallopeau, all of whom declared the patient to be a leper. In some Oriental countries leprosy assumes a much severer form than it does in Brittany, where the disease often remains abortive, and appears to inexperienced observers as an entirely different or even perfectly new disease, and as such Morvan described it. His syringo-myelitis, however, comprises, according to Dr. Zambaco, various diseases which should be separated; one division clearly representing "lepra anæsthetica," as von Daniellsen has described it; while others still lack an exact description. Permanent residents of Constantinople are not subject to leprosy, and in those rare instances in which it has been acquired it has always been found that the ancestors of the patients had lived in the Cyclades or other islands of the Greek archipelago.

#### THERAPEUTICS IN THE WESTERN INFIRMARY, GLASGOW.

It would be wrong to say therapeutics is conspicuous by its absence from the clinical teaching in the University of Glasgow, but it is a striking fact that the Professor of Therapeutics has no beds at his disposal with which to illustrate his teaching on the uses of medicines. This is a most unusual and anomalous state of matters, contrasting with that of the other Scotch universities and other medical schools. There is at present a vacancy for a visiting physician in the Western Infirmary, and it does seem most reasonable that it should be filled by one occupying so responsible a post as the Professor of *Materia Medica* and Therapeutics, to say nothing of the personal fitness and claims of Professor Charteris, which will be everywhere recognised. It is due to the students that such an appointment should be made, and that the right use of medicines in the treatment of disease should be demonstrated by one whose special function it is to study them and their action. Professor Charteris, besides being Professor of *Materia Medica* and Therapeutics, has had large experience in teaching clinical medicine in connexion with the Royal Infirmary of Glasgow.

#### THE DIGESTIBILITY OF TRIPE.

WE have been challenged to pronounce an opinion on the dietetic virtues of tripe, an article of food which is largely consumed in certain parts of the country, especially during the winter months. Tripe consists of the soft muscular walls and mucous membrane of the stomach of ruminant animals with a small proportion of delicate omental fat adhering, from which, however, all fibrous portions of the serous covering, or peritoneum, have been removed. From frequent experiments it has been proved that tripe stands high in the list of albuminous substances that are quickly acted on by the gastric juice and reduced to a state of solution, and has therefore acquired a reputation for digestibility. But plain boiled tripe in itself is a very insipid article of food, and in order to make it palatable the art of the cook has to be invoked, which, whilst making it more "savoury," causes it often when so served to be an offence to the stomach. The usual mode of serving tripe in this country is to boil it with milk and onions, and there can be little doubt that such a combination is not particularly digestible. Tripe is also sometimes fried in batter, but unless very carefully cooked it is apt to become leathery. If only plainly boiled in water it requires a considerable amount of condiments in the shape of salt, pepper and mustard to make it acceptable to the palate. There-

fore tripe, as usually cooked, though an excellent dish for strong stomachs, is, owing to the ingredients added to it, not always so suitable for persons of weak digestion as has been supposed. One interesting point regarding the consumption of tripe is the local favour it receives in different parts of the country. It is a favourite dish among the artisans of the large towns in the midlands, whilst it is apparently disregarded in the south and west. A similar local partiality prevails in France, where Normandy has acquired a special repute for the dish *tripes à la Normandie*, which is served in many Parisian restaurants as a delicacy of no mean merit. London also consumes a large quantity, where during winter it is a favourite supper dish among the artisans and lower middle classes. The preparation of tripe, as far as London is concerned, is in the hands of only a few firms, who supply the small retail shops. London tripe, moreover, has obtained a high repute on the Continent, one firm exporting annually £40,000 worth, chiefly to Russia and Baltic ports.

### THE NEW FEVER HOSPITAL.

THE events of the week only emphasise our recent remarks on the magnitude of the task devolved by the Legislature on the Metropolitan Asylums Board. Chief among these was the inspection of the new North-Eastern Hospital at St. Ann's-road, Tottenham. This hospital, meant for the accommodation of 456 patients and 207 officers, has been built and furnished in about six weeks by 900 men working under about twenty firms. The original site was fifteen acres, but it is proposed to buy neighbouring land to the extent of four acres more with property on it. It seems only fair, when buildings for fever are erected, that the owners of property immediately affected should be compensated or bought out. Some idea of the extent of the building will be gathered from the fact that a wall of 800 ft. in length has been erected next St. Ann's-road and a 7 ft. fence on the remaining sides. The buildings comprise twenty-two ordinary patients' blocks, two isolation blocks, two administrative blocks, store blocks, dormitories, laundries, disinfecting rooms &c. The whole are built of wood, with every device for warmth, ventilation &c., the architects being Messrs. A. & C. Harston. The responsible post of medical superintendent of this hospital has been given by the Managers to Dr. R. A. Birdwood, lately medical superintendent of the small-pox hospital ships, who will doubtless give a good account of the cases committed to him.

### WATER-SUPPLY IN SOUTH LONDON.

THE analyst to the Board of Works for the St. Saviour's District, Southwark, has recently reported that samples of the water obtained from the mains of the Southwark and Vauxhall and Lambeth water companies were decidedly impure and almost sufficiently bad to be condemned as unfit for drinking. In support of this statement the following results of analyses in grains per gallon were handed in:—Total solid matter, Southwark and Vauxhall, 18.50; Lambeth, 19.00; loss on ignition, 3.00 and 3.00; mineral solids, 15.50 and 16.00; albuminoid ammonia, 0.0085 and 0.0070; combined chlorine, 1.25 and 1.30; oxygen required, 0.063 and 0.073; hardness, 12.4 degrees and 12.4 degrees. Although these figures contrast unfavourably with those obtained in July last and later in October, we are not disposed to admit that they are evidence of any decided or gross pollution. As will be seen, out of from 18.50 to 19.00 grains of total solid matter from 15 to 16 grains are of mineral character, the combined chlorine being 1.25 and 1.30 and the hardness 12.4 in both instances. The loss on ignition was equivalent to 3 grains, which might or might not have been objectionable matter; there is no evidence to show. Moreover, the water was free from taste and odour, and when viewed through a 2 ft. stratum was clear and of a yellowish-green tint. These

data are hardly sufficient, we think, to establish for certain that the water was seriously contaminated. The quality of the metropolitan water cannot, of course, be expected to improve, seeing that the supply is running shorter every year, and the risk of pollution is consequently becoming greater. However, there is every hope that the labours of the Royal Commission on Water Supply, which resumed its sittings on Wednesday last, will not be in vain. But in the meantime it is very right that pressure should be brought to bear upon the existing companies by conducting independent chemical analyses of the water from time to time, so that at least efficient filtration may be ensured. The results, however, require very careful consideration before a conclusion based on such analyses can be arrived at. It will be interesting to compare the above analysis with the report on the Lambeth and Vauxhall water, which will be issued shortly by the official experts, Messrs. Crookes, Odling and Frankland.

### THE MEDICAL SOCIETIES.

THE Medical Society of London will open on the evening of Oct. 17th, at 11, Chandos-street, Cavendish-square, with an address by the President, Mr. Hutchinson, F.R.S., on "Names and Definitions in Disease." A number of papers of importance have already been promised. Dr. Bristowe, F.R.S., will deliver the Lettsomian lectures on "Syphilitic Affections of the Nervous System." The annual oration will be delivered by Professor W. Mitchell Banks, F.R.C.S. A considerable number of new Fellows have joined the Society, and the session promises to be a busy and successful one. The Pathological Society of London will hold its first meeting on Tuesday, Oct. 18th; the first meeting of the London Clinical Society will be held on Oct. 14th; and the Royal Medical and Chirurgical Society of London will inaugurate its session on Oct. 25th. The meetings will be held at 20, Hanover-square, W., and will commence at 8.30 P.M. The first meeting of the Hunterian Society will be held at the London Institution, Finsbury-circus, E.C., on Wednesday, Oct. 12th, at 8.30 P.M., when the first Hunterian Society lecture for the Session 1892-93 will be delivered by Dr. Robert Barnes on Some Observations on Absorption in relation to Physiology, Pathology and Therapeutics.

### ALLEGED INSANITARY HOUSES.

THE daily journals have done good service in calling attention to the need for remedy of insanitary conditions that are to be found in houses occupied by poor persons. But in these cases everything depends upon accuracy of statement, and we fear that unless this habit of accuracy is cultivated a tendency to disregard the utterances of the press will be eventually encouraged. At a meeting of the vestry of St. James's last week a statement recently made by an evening contemporary was discussed. This statement was to the effect that in a number of streets in that district "almost every house was full of dirty, stinking, home workshops, whose doors were tight-locked against a stranger." We quote from a report of these proceedings in *The Times*. The clerk had written to the editor of the evening journal and asked for a list of the premises referred to. A reply was received mentioning a considerable area, and hinting that certain property alleged to be owned by a member of the vestry was so notoriously overcrowded and deficient in sanitary accommodation as to lead to the belief that it must have come under the notice of the officials. Further requests for detailed information met with no greater success, and finally the medical officer of health said the charges were extremely vague and would involve him in a great amount of investigation to answer specifically. All he could say was that the matter was very grossly exaggerated in the article referred to and that there was substantially no truth in it.

If there is any foundation for the statements made in the evening journal to which we refer there ought to have been no difficulty in supplying the sanitary authority with the information necessary to enable it to remedy the evils complained of. General charges of the sort made tend only to discourage sanitary administration, and certainly tend to minimise the influence of the press. If this should result it would be greatly to be deplored, for it is chiefly owing to the influence of the press that so much good work is being done at the present time.

#### THE SCOTCH MEDICAL SCHOOLS.

THE colleges now remaining to be opened are those of Edinburgh, Aberdeen, Dundee and Glasgow. Aberdeen University will commence its winter session on Oct. 11th and Edinburgh College and University College, Dundee, will open on the same date. On the 18th the winter session in the faculty of medicine will be commenced at Glasgow University, when an inaugural address will be delivered by Professor Cleland, M.D., on "Anatomy: its Place in Education"; the students of Anderson's College will listen to an address by Dr. W. L. Reid and Professor McVail will deliver the introductory address at St. Mungo's College; whilst the lecturer on Gynæcology at the Western Medical School will open the session with an address on "Early Ovarian and Tubal Disease."

#### MEDICAL OFFICERS OF HEALTH.

AN evening contemporary has recently published letters from correspondents bearing upon the question whether medical officers of health should devote the whole of their time to their official duties. It is urged that the time has come when this system should be everywhere adopted, and to this claim we see no objection. But if the whole of the time of capable and reliable men is wanted by the public, some effort must be made to induce sanitary authorities to offer adequate remuneration. The present is not a time favourable to the full development of an efficient health service. The salaries which are often proposed bear no relation to the responsibilities and anxieties attaching to the office, and the disposition to abolish pensions renders the appointment of much less value than hitherto. When, in addition to this, the authorities further propose that their officers shall retire at a fixed age the candidate is led to think of what opportunity he will have of saving money wherewith to provide for the later years of his life. If the officer is allowed to keep in touch with other work he may look to this to provide for him when he leaves the public service. There is therefore something to be said against the whole-time system, which can only be generally adopted when the public is prepared to remunerate its officers adequately.

#### THE VACANT CORONERSHIP OF EAST DENBIGH.

THE election to the office of Coroner for the Eastern Division of the County of Denbigh, vacant by the death of Mr. B. Heywood, will, it is announced, take place on Nov. 7th next. We understand that several applicants for the post are already in the field. On the respective claims of the candidates to fill this important and time-honoured office we do not propose to offer more than a bare opinion. Their antecedents are not for the most part sufficiently well known to us to warrant anything but a general statement, to the effect that, so far as we are aware, they are all more or less fitted to aspire to the dignity of the coronership. To this, however, we must add the reservation that in the case of most of them the want of a medical qualification is, *primâ facie*, in our view a distinct drawback. But with regard to one of the candidates, Dr. Edward Davies of Wrexham, no such hesitation on our part is

either necessary or justifiable. A mere enumeration of the qualifications possessed by that gentleman will suffice to mark him out as pre-eminently worthy to obtain the suffrages of the electors in the approaching struggle. Dr. Davies has acted as deputy coroner for several months past, has lived in the principality all his life, and for over thirty years has practised his profession in Wrexham; moreover, his long experience in connexion with the coroner's court, in behalf of which he has for more than a quarter of a century conducted the post-mortem examinations, renders him peculiarly well fitted to discharge the duties of the office in question. In the interest of the inhabitants generally, we cannot but wish success to the candidature of Dr. Davies.

#### HEALTH MATTERS IN LEICESTER.

THE *Leicester Daily Post* discusses in a leading article several matters of interest in respect of the spread of disease. The chief of these is the disclosure by the chairman of the Sanitary Committee to the Town Council of "the ignorance or the intolerable carelessness" of practitioners in sending cases to the Fever Hospital as scarlet fever cases in which there was no scarlet fever, but measles, or even only a swollen gland. We know nothing of the details of these cases or of the justice of the charges of inaccurate diagnosis, but the charges themselves are serious enough to demand the attention of practitioners. Another point is that a local epidemic of typhoid fever has been distinctly traced by the medical officer of health to herb beer being sold in a shop where there were five cases of the disease. There has also been a "mysterious visitation of small-pox," which has not yet been satisfactorily traced.

#### INTESTINAL BACILLI.

THE bacilli found in the intestines have from time to time given rise to a good deal of controversy, and so far as appearances go there is every probability that the paper warfare will continue just as briskly as it has done in the past. In all the earlier literature concerning the bacillus coli communis this organism was spoken of as a simple saprophyte, but certain observers who maintained that it was not identical with Eberth's typhoid bacillus eventually suggested that it might be a cause of cholera nostras. Latterly a number of observers, amongst whom must now be reckoned Dr. Gabriel Vallet,<sup>1</sup> have come to the conclusion that these two organisms are really identical. Of course there are certain facts which tend to strongly support this thesis, although it must be confessed that, for the present at any rate, it is better to keep an open mind on the subject. However, the following facts may be cited in favour of Dr. Vallet's position. At first a considerable number of observations on typhogenous water were made, as a result of which it was stated that the typhoid bacillus was invariably found; but since investigators have come to recognise certain distinctive characters in the two organisms the bacillus coli communis is now described as occurring in typhogenous water much more frequently than is Eberth's typhoid bacillus; then, again, from careful bacteriological examination of typhoid stools it has been ascertained that the bacillus coli communis is found therein much more frequently than the typhoid bacillus itself, which is, indeed, comparatively rarely met with. After a careful morphological and biological investigation, taking the above facts into consideration, Dr. Vallet has come to the conclusion that the bacillus coli communis of Escherich is nothing more than a transition stage of Eberth's typhoid bacillus, and that there are, in fact, just as Loeffler, Roux, Yersin, Klein and others have described in diphtheria, two forms of the same organism—a pathogenic and a non-pathogenic. Some of the distinctive characters are most

<sup>1</sup> Le Bacillus Coli Communis dans ses Rapports avec le Bacille d'Eberth et l'Étiologie de la Fièvre Typhoïde.

important and those who hold that organisms may become markedly modified as they grow under very different conditions will find considerable evidence in support of their position in these observations. The bacillus coli communis may be cultivated, and will remain for a considerable length of time in liquid taken from privies and water-closets and then sterilised; whilst the typhoid bacillus, when placed under similar conditions, not only ceases to multiply, but dies out—in from one to two weeks. Acting on the idea suggested by this experiment, Dr. Vallet found that when the bacillus coli communis is cultivated in faecal solutions it becomes much more virulent, sometimes even more so than the ordinary typhoid bacillus; and he points out, therefore, how important it is to prevent fermentation of faecal matter. He maintains, indeed, that Murchison was perfectly correct in his statement that typhoid fever can arise quite independently of an anterior cause, by fermentation of this faecal matter. He also insists upon the important part played by malnutrition and exhaustion in the etiology of typhoid fever, holding, as he does, that it is only when the tissues are exhausted and the secreting surfaces are acting irregularly or imperfectly that any of these forms of the bacillus can exert any pathogenic effect. The article is exceedingly interesting and some forcible arguments are advanced, but we cannot agree that Dr. Vallet has by any means proved his position to be invulnerable.

#### THE ROYAL COMMISSION ON WATER-SUPPLY.

THE Royal Commission appointed to consider the question of the London water-supply resumed their sittings yesterday, Lord Balfour of Burleigh presiding. The first witness, Mr. Thomas Hawksley, C.E., stated that he estimated that over the Thames area of 3736 miles the rainfall would be six inches in the driest year, and that would give an average of 887,000,000 gallons; that was the quantity that might be obtained at the end of fifty years, and taking 500,000,000 from the Thames area, that would mean about twenty-five gallons per head per day, as all the supply from the Thames that the water companies could reckon upon. His experience was that not more than twenty gallons per head per day was used for domestic and ordinary trade purposes. At that rate the supply, would carry them over twenty-five years. Questioned as to whether cholera is not occasioned by the water-supply, the witness said it was not, but added that it could be communicated where the water was highly polluted, and had no chance of being oxidised, as in the case of the Golden-square wells. Cholera, he pointed out, always goes up rivers, and not down them, because oxidation is more rapid where the river broadens than where it is narrow. Sir Frederick Bramwell, who followed, said he thought the consumption per head per day could be reduced to twenty-six gallons, instead of, as at present, thirty-two gallons. There was a great deal of water that now ran to waste without the knowledge of the people, who would not object to the waste being saved. After hearing the evidence of Mr. Peregrine Birch, who stated that in his opinion 175,000,000 gallons, in addition to the quantities of water now taken from the Thames, might be taken without injury to the river, the Commission adjourned.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Buda-Pesth.*—An important proposal has been made by the professorial Senate of the Medical Faculty which, if sanctioned by the Government, will alter the examinations considerably in the direction of diminishing the Mineralogy, Zoology and Botany required and increasing the Pathology and Therapeutics, besides which some one practical subject, such as Dermatology or Laryngology, will have to be taken up. It is also proposed that no degrees from Vienna and other Austrian universities shall entitle the holder to practise

in Hungary unless he shall have spent five semesters at a Hungarian university.

*Clausenburg.*—Dr. Szabó of Buda-Pesth has been appointed to the chair of Obstetrics and Gynaecology.

*Königsberg.*—Dr. Kuhnt, professor at Jena, has been appointed to the chair of Ophthalmology in succession to Professor von Hippel.

*Naples.*—Dr. G. Melle has been recognised as *privat-docent* in Dermatology and Syphilography.

*Kazan.*—Dr. L. O. Darshévich of Moscow has been appointed to the Professorship of Nervous Diseases.

*St. Petersburg.*—Military Medical Academy: Dr. N. V. Sokoloff, formerly Professor of Physiological Chemistry, has obtained the sanction of the Professorial "Conference" to recommence lecturing in the capacity of *privat-docent*.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Poincaré, Professor of Hygiene in the Nancy Medical Faculty.—Dr. Tracou, Professeur Agrégé in the Medical Faculty of Lille.—Dr. A. Kruse, *privat-docent* in General Pathology and Morbid Anatomy in the University of Greifswald.—Dr. John J. Reese, Professor of Forensic Medicine and Toxicology in the University of Pennsylvania.—Privy Councillor Dr. Steintal, the *doyen* of the Berlin physicians and a well-known philanthropist, died on the 2nd inst. at the patriarchal age of ninety-four years.

BARON LÉON DE LENVAL of Nice offers a prize of 3000 fr. to the inventor of the best application of the principles of the microphone in the construction of a portable apparatus for the improvement of hearing in deaf patients. Instruments for competition should be sent to Professor Adam Politzer or Professor Victor V. Lang, Vienna, before Dec. 31st, 1892. The prize will be awarded at the Fifth International Otological Congress to be held at Florence in September, 1893. If no instrument is judged worthy of the prize, the jury reserve the right of announcing another competition, unless Baron de Lenval decides to otherwise dispose of the prize. The members of the jury are:—Professor Adam Politzer (president) and Professor Victor V. Lang, of Vienna; Dr. Benni, Warsaw; Dr. Gellé, Paris; Professor Urban Pritchard, London; Professor St. John Roosa, New York; Professor Grazzi, Florence.

PRELIMINARY to the improved water-supply of Florence, shortly to become a *fait accompli*, there was opened on the 2nd inst. in the neighbouring San Casciano a magnificent service of *aqua potabile*. The works, designed and carried to completion by the engineer, Dino Ugoccioni, were greatly admired by the experts invited to witness the ceremony, while the water itself, from a pure and abundant source, satisfied every test applied to it.

THE provincial medical officers in Denmark are evincing grave dissatisfaction with their position, their work being exceedingly heavy and their salaries most inadequate. They are beginning to refuse to continue to act, and the medical press urges them on and expresses hopes that no other medical men will consent to accept appointments until the pay per visit is materially improved.

DR. PAOLO FIORDISFINI, late director of the Manicomio of the Santo Spirito in Rome, of whose life and labours we recently gave some account, was, on the 30th ult., interred in the Church of S. Antonino de' Portoghesi (the National Church of the Portuguese) in presence of a large assemblage of the profession and of other learned bodies. The leading citizens, were also represented.

OUR Special Correspondent telegraphs from Sydney, New South Wales, that the Medical Congress being held in that city during the week has been a complete success. More than 600 members attended the meetings, and over 160 papers on various medical subjects have been announced.

ON Tuesday the Marchioness of Lorne, accompanied by Prince and Princess Henry of Battenberg, opened an extension of the Aberdeen Infirmary. The estimated cost of the extension will be about £30,000.

THE annual dinner of past and present students of Charing-cross Hospital will be held on Oct. 21st at the Holborn Restaurant at 6.30 for 7 P.M. Tickets (5s. 6d. each) may be obtained from Mr. Robert D. Muir.

SIR WILLIAM SAVORY is announced to deliver the opening address of the North London Medical Society in the Clinical Theatre of the Great Northern Hospital on Thursday, Oct. 20th, at 8.30 P.M.

## OPENING OF THE MEDICAL SCHOOLS.

### ST. BARTHOLOMEW'S HOSPITAL.

THE annual dinner of old students took place in the great hall of the hospital on Monday, Oct. 3rd. The chair was taken by Dr. W. J. Russell, F.R.S., Lecturer on Chemistry to the hospital. Among those present were: Sir James Paget, Bart., Sir Frederick Abel, Sir Richard Quain, Bart., Sir William Savory, Bart., Sir George Humphry, Mr. Bryant, Dr. Clifford Allbutt, Regius Professor of Physic in the University of Cambridge, and most of the members of the medical and surgical staff. Over 100 old students were present. After the loyal toasts had been duly honoured Mr. Howard Marsh gave "The Army, Navy and Reserve Forces," for which Messrs. Strickland, Jones and D'Arcy Power responded. Sir George Humphry responded for "The Old Students." The health of the recently elected treasurer of the hospital, Sir Trevor Lawrence, was given by Sir William Savory. The health of "The Visitors" was proposed by Sir James Paget, and to this Dr. Clifford Allbutt and Sir Richard Quain responded. After the healths of the chairman and the secretary, Dr. Hensley, had been heartily drunk, the party adjourned to the library, and a most pleasant reunion of old students was brought to a close.

### KING'S COLLEGE HOSPITAL.

The annual dinner of the old students of King's College Hospital was held on Monday last at Limmer's Hotel, Professor I. Burney Yeo occupying the chair. This dinner, which now replaces the former inaugural address, attracted a very large gathering of old students and friends, eighty-five having notified their desire to be present, and although at the last moment sundry inevitable telegrams of regret were received, the attendance was large and the proceedings enthusiastic. Amongst those who spoke were the following: Professor Burney Yeo, Colonel Mackinnon, who responded to the toast of "The Army and Navy"; Rev. Dr. Wace, principal of King's College and chairman of the hospital committee of management; Professor William Rose, who proposed "Country Friends," for whom Dr. Allfrey of St. Leonards replied; Dr. Fenn of Colchester, who proposed the toast of "Town Friends," responded to by Mr. Thomas Bond of the Westminster Hospital. Professor A. B. Duffin, Mr. Richard Twining, Mr. T. H. Cheater of Burford, Mr. J. H. Salter of Kelvedon and Dr. Tirard also spoke. As evidence of the interest shown in these gatherings it was mentioned that one country friend had that day travelled over 200 miles to be present at the dinner.

### ST. THOMAS'S HOSPITAL.

At 4 o'clock on Monday, Oct. 3rd, the annual prize distribution was held in the governors' hall, Mr. Wainwright, treasurer of the hospital, in the chair. After a few preliminary words the chairman introduced Sir John Lubbock, who then gave the prizes and certificates of honour. The prize

medals were then presented: The Mead medal for Practical Medicine to Mr. A. R. O. Milton; the Cheselden medal for Surgery to Mr. W. G. Sutcliffe; the Sully medal and prize for excellence of Surgical Reports to Mr. W. B. Winston; and the treasurer's gold medal for General Proficiency and Good Conduct to Mr. E. Smith. The Dean of the school then made a few remarks on the present condition of the school, changes in the staff and alterations in the building. Sir John Lubbock then gave his address.

A vote of thanks to Sir John Lubbock for his address was afterwards proposed by Sir H. Doulton and seconded by the treasurer. Tea and coffee were provided in the committee-room for the governors and their friends; light refreshments were also provided in the library. Many of the visitors availed themselves of the opportunity to visit the hospital and medical school. In the evening the annual dinner was held in the Whitehall Rooms of the Hôtel Métropole, and there was a most successful reunion of past and present students of the hospital, about 160 being present. The chair was taken by Dr. Bristowe, F.R.S., in the unavoidable absence of Mr. Henry Laver, J.P., of Colchester. After dinner the usual loyal toasts were drunk, and then Dr. Bristowe proposed "St. Thomas's Hospital," and alluded to the cordial relations existing between the governors and the medical staff. The treasurer of the hospital, Mr. J. G. Wainwright, replied. Dr. Ord proposed "The Visitors," and Mr. Phillips and Mr. F. Walker responded on their behalf. "The Medical School," proposed by Mr. Wainwright, was responded to by the Dean, Mr. G. H. Makins. Dr. Payne proposed "The Chairman," who responded. Mr. MacKellar proposed "The Old Students," a toast acknowledged by Dr. Wyman and Dr. Nichol. "The Hon. Secretaries" was proposed by Dr. Rolla Rouse, and Dr. Turney and Mr. Stahl briefly replied. A pleasant feature during the dinner was the interchange of courtesies with University College Hospital, which was holding its annual dinner in another part of the building.

### MIDDLESEX HOSPITAL.

The Introductory Address was delivered by Dr. Sidney Coupland in the large lecture theatre, to a crowded audience of students and their friends. At the conclusion of the address Dr. Pasteur (Secretary of the Medical School) read the Dean's statement for the past year. The prizes gained during the preceding year were then distributed by Sir Lionel S. Pilkington, Bart., one of the vice-presidents of the hospital, who brought the afternoon's ceremony to a close with a few well-chosen words of advice to his hearers. A well-attended reception was afterwards held in the dining-hall of the residential college.

In the evening an unusually large number of past and present students attended the annual dinner at the Holborn Restaurant. Dr. Wm. Duncan presided, and among the guests present were Sir Lionel Pilkington, Baron Rowland, M.D., Mr. Bell-Sedgwick, Mr. Vowles, the Rev. Hay Chapman, Mr. Wilhelm Ganz and others. The evening passed off most pleasantly, the usual speeches were enthusiastically received, and the admirable playing of Mr. Wilhelm Ganz was a feature of the musical part of the programme.

## CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

FROM the Calendar of this institution, which has just been published by the Council, it appears there are 1110 Fellows of the College (of whom 830 obtained the Fellowship by examination, 15, who were Members of twenty years' standing, were elected Fellows, and 2 are *ad eundem* Fellows), 16,771 Members, 704 Licentiates in Midwifery and 793 Licentiates in Dental Surgery. The holders of the diploma in Public Health (granted in conjunction with the Royal College of Physicians) number 126.

During the past collegiate year 687 candidates presented themselves in elementary anatomy and elementary physiology, of whom 484 passed in both subjects, 50 in elementary anatomy, 105 in elementary physiology, and 48 candidates were referred in both subjects; 89 candidates presented themselves in elementary anatomy only, 78 of whom passed; 57 presented themselves in elementary physiology, of whom only 47 passed. The examiners are appointed in conjunction

with the Royal College of Physicians. The fees received from candidates for this examination amounted to £4048 16s., the examiners receiving as fees £573 15s. Of 753 candidates who presented themselves in chemistry, 504 passed and 249 were referred. Of 976 candidates who presented themselves in materia medica, 549 passed and 427 failed. The examiners in Chemistry and Materia Medica are elected by the Royal College of Physicians.

The examiners in Anatomy and Physiology for the Second Examination are appointed annually in conjunction with the Royal College of Physicians; they have conducted the Primary Examination under the old regulations, as well as the Second Examination of the Examining Board. 771 candidates presented themselves in anatomy and physiology, of whom 365 passed in both subjects, 152 passed in anatomy only, 64 passed in physiology only and 190 were referred in both subjects; 109 presented in anatomy only, 84 of whom passed and 25 failed; of the 178 who presented themselves in physiology only 117 passed and 61 failed. The fees received from these examinations amounted to £4291 17s. 6d., the examiners receiving in fees £1621 5s.

The Board of Examiners in Anatomy and Physiology for the diploma of Fellow, consisting of nine members annually elected by the Council, held during the past year two examinations, at which 155 candidates presented themselves, of whom 64 passed and 91 were rejected. The fees received amounted to £1018 10s. and the fees paid to the board to £697 10s.

The Court of Examiners consists of ten members, elected by the Council for five years from the Fellows of the College. They conduct the Third or Final Examination in Surgery of the Examining Board, as well as the Pass or Final Examination under the old regulations, and the Pass or Final Examination for the Fellowship. During the past collegiate year the Court has held two examinations for the Fellowship and four for the Membership. At the former there were 66 candidates, 46 of whom passed, 4 being referred for one year and 16 for six months. For the Membership there were 926 candidates, of whom 532 passed and 394 were referred. The fees paid by candidates amounted to £10,104 18s., and the fees paid to the Court of Examiners and the Examiners in Midwifery to £5792 11s. The Examiners in Medicine, under the scheme for an Examining Board in England, are elected by, and the Examiners in Midwifery in conjunction with, the Royal College of Physicians. Of the 839 candidates who presented themselves in Medicine during the year 521 passed and 318 were referred; in Midwifery, of 791 candidates 542 passed and 249 were referred.

The Board of Examiners in Dental Surgery, consisting of eight members, are elected by the Council for five years, and have held two meetings for the examination of 81 candidates, 51 of whom received their diplomas. The fees paid amounted to £535 10s.; of this the board received as fees £340 4s.

The Examiners in Public Health, appointed in conjunction with the Royal College of Physicians, have examined 58 candidates in Part I., 49 of whom passed and 9 were referred. For Part II. 52 candidates presented themselves, 40 of whom passed and obtained the diploma and 12 were referred. The fees paid by candidates amounted to £276 3s. and the fees to the examiners to £231.

With regard to the finances of the College, it appears that the income from all sources amounted to £39,619 10s. 1d., the largest receipt being, as already shown, derived from the fees paid by candidates for the diplomas of the College—viz., £20,275 14s. 6d., the next largest being from sale of stock, £11,248 14s.; investments, £5879 1s. 9d.; rent from chambers adjoining College, £665 3s. 1d.; incidental receipts—i.e., hire of rooms, sale of calendars, questions &c.—£540 11s. 4d.; trust funds, £251 16s. 11d.; fees retained for candidates, £660 10s.; balance at banker's, Midsummer Day, 1891, £97 18s. 6d.

The expenses for the year amounted to £39,283 6s. 10d., leaving a balance at Midsummer Day, 1892, of £336 3s. 3d., the largest item being for extension of College premises—viz., £10,209 6s. Fees to examiners amounted to £9256 5s.; half of the expenses for the Examination Hall and laboratories, £5373 4s. 4d.; salaries, wages and pensions for officers and servants in the three departments, museum, library and office, £4927 2s. 2d.; rates, taxes and insurance absorbed the sum of £1003 9s. 3d.; extraordinary expenses, £1959 2s. 7d.; fees returned to candidates, £560 10s.; alterations and repairs, £676 11s. 9d.; fees to council, £289 16s.; law expenses, £755 16s. 3d.; purchase of books &c. for library, £662 8s. 11d.; lectures, specimens, catalogue &c., for museum department,

£816 0s. 6d.; whilst under the heading of miscellaneous items, fuel, light, printing, stationery, trust funds &c., about £3000 appears to have been expended.

## CHOLERA.

CURRENT NOTES, COMMENTS, AND CRITICISM.

WHILST the cholera has shown marked signs of diminution in Hamburg, and is slowly but steadily declining in Paris and St. Petersburg, it still continues very prevalent in certain provinces of Russia, and it has broken out at Buda-Pesth. It also continues to prevail to some extent in Holland, Galicia, and at Havre, Antwerp and Cracow.

At Hamburg the total number of cases during the six weeks since it first appeared amounts to 17,701, and the aggregate number of deaths up to the latest official returns is 7536. It is stated that most of the public schools either have already opened or will resume work next week. The outbreak in the Hungarian capital, Buda-Pesth, seems to have been sudden and somewhat severe, affecting especially the quarters on the left bank of the Danube. As in the case of Hamburg, the drinking water is obtained from the river. The authorities at Buda-Pesth were not without some preliminary warning of what was likely to occur. It is alleged that there was at first, when the number of seizures left no doubt of the presence of the epidemic, a great want of preparedness on the part of the municipal authorities to meet the exigencies of the case, and that this had given rise to much popular dissatisfaction and apprehension—in Vienna especially. Whether this may have been the case or not, there is no doubt that the authorities at Buda-Pesth soon set to work in the direction of providing additional hospital accommodation and sick transport. It must always be borne in mind that there is a general disposition to do as little as possible where financial considerations are involved, and to raise a great outcry when it is afterwards discovered that the penalty has to be paid for any neglect or inadequate arrangements.

The reply published by the Chief of the Foreign Affairs Department to the alleged granting of clean bills of health to vessels leaving Hamburg after the outbreak of cholera appears to be a precise and straightforward statement of facts. It supplies us with certain data in regard to the manifestations of the epidemic in that city which it may be of interest to record with reference to the complaints that have been made about the steamships *Moravia* and *Normannia*. According to the official register, the *Moravia's* certificate was issued on Aug. 16th, when there was not the slightest suspicion at Hamburg of an outbreak of cholera. Through the published statements of experts it is known that unmistakable indications of the disease were not discovered until the 22nd of August, and it was still doubtful on the 23rd and 24th of August whether the disease was of an epidemic character. At the latter date the Senate ordered a daily report to be issued, and that the opinion of Professor Koch, who was in the city at the time, should be taken. Bills of health, which had been drawn up on the 24th but not delivered, were withheld, but that for the *Normannia*, dated the 24th, had already been delivered to the ship before the issue had been suspended.

It may also be well here to correct a very general misapprehension that prevails as to the part played by the Jewish Russian emigrants in the spread of this disease. It is the prevailing notion that cholera was conveyed by them and followed everywhere in their track. It is pointed out, however, by a correspondent, in the *St. James's Gazette* of the 5th inst., that such was not the case. As far as Germany is concerned, cholera first broke out in Hamburg, and it was not taken there through Germany by Russian Jews. The earliest cases occurred in the port of Hamburg among the labourers and sailors. The disease had been present in France long before, and in Eastern Russia and St. Petersburg some time before the occurrence of the outbreak in Hamburg. Exactly how it got there, and how the water-supply became infected, are matters still requiring the most careful and minute investigation.

We notice that, owing to the increase of cholera at Buda-Pesth, the military authorities have ordered that tea with citric acid should be supplied to the troops. We prefer the use of a sulphuric-acid-ade. The garrison has remained free from cholera. A bacteriological examination of the alleged

cases in the garrison hospital showed that they had not died of Asiatic cholera. It would seem, by the way, that different varieties of the bacillus had been detected in the course of this epidemic, and it might be interesting to refer to Dr. Cunningham's researches published in Part VI. of the Scientific Memoirs of the Army Medical Officers of India. This officer states, we believe, that he has discovered ten different varieties of the bacillus. If this be so, it will tend to widen our knowledge of the different forms assumed by cholera, that is, on the assumption that Koch's bacillus be the specific cause of that disease.

It seems to become clearer every day that a further extension and development or revitalisation of this epidemic disease may be anticipated during the summer and autumn of next year, and practically the lesson which has to be driven home is, that we should during the interval see to our water-supplies, drainage and general cleanliness, and to the organisation of our methods of procedure should the epidemic unhappily obtain any foothold hereafter in this country. It has not done so yet, and there is no reason why it necessarily should do so. Still, whatever we may do now to protect us from cholera is not thrown away—it is equally useful against other diseases. In view of the wisdom and foresight so far exhibited by the medical department of the Local Government Board, we think the country may feel satisfied that these things will not be lost sight of, and it only remains for the people to render all the aid they can.

A suspicious case of cholera is reported from St. Thomas's Hospital, to which institution a patient was admitted on Sunday morning last, Oct. 2nd. It appears that on Friday, Sept. 30th, the patient was taken ill with profuse diarrhoea, the stools having the rice water appearance so characteristic of the malady, and suffering from cramps in the limbs and from violent thirst. After having had eight pints of saline solution injected into the veins improvement was apparent, and this was maintained for twenty-four hours, but a relapse subsequently supervened. The patient now is slightly better but still collapsed. It has not been possible to trace any source of the infection and the cholera bacillus has not been isolated. The case is under the care of Dr. Ord.

## THE CHOLERA IN FRANCE.

(FROM OUR SPECIAL CORRESPONDENT.)

### THE CONFLICT OF THEORIES.—THE ICE SUPPLY.—THE SUBURBAN CESSPOOLS.

NOTWITHSTANDING the slight increase in the number of deaths due to cholera, which followed and perhaps was caused by the *fête* of Sept. 22nd, the epidemic seems decidedly on the wane. As already mentioned, there was an average daily death-rate of twenty-four in Paris during the first twelve days of September. It will be found, in all probability, that this average fell to about ten per day towards the end of the month. Still it is impossible to feel any sense of security. The fact that the last cholera epidemic did not commence until the month of November is a very disquieting consideration. Though the present outbreak of the disease seems to be gradually dying out, it is like a smouldering fire which may blaze forth again at any moment. At Hamburg it can be said that the cholera has pretty well exhausted itself, while in Paris a pessimist might argue that we have only as yet seen the forerunners of the epidemic. Then there is another grave consideration. At first it seemed very probable that the drinking of the Seine water was the only cause or vehicle of cholera. Up to the middle of August it was the suburban population who drank Seine water after it had passed through Paris who were the chief sufferers. The cases that occurred in Paris and in districts where other than Seine water was drunk were not numerous. It was therefore easy to suppose that the victims had gone for business or pleasure to the dangerous suburbs, and while there had drunk the Seine water, or had been in personal contact with a case of cholera. This theory engendered a sense of false security. It seemed simply necessary to avoid drinking the Seine water or else to boil it very carefully. But in September the tables were turned. It was Paris, where no Seine water was consumed, that suffered most and the Seine water-drinking suburbs least. In September there were twice as many deaths in Paris as in the suburbs. Evidently a large proportion of these deaths

within Paris was due to other causes than the drinking of the Seine water. In the suburb of Aubervilliers, where so many cases of cholera had occurred, an artesian well had been dug, and the inhabitants were offered other than Seine water to drink. Simultaneously with the opening of this new water-supply the prevalence of cholera at Aubervilliers notably decreased. Could there be a better confirmation of the Seine-water theory? But if one looks more closely into the matter the theoretical result of the experiment is not so evident. The commune of Aubervilliers spreads over a large district, and a very considerable proportion of the cases of cholera occurred at a distance of more than a mile from this new well, close to the walls of Paris, near the Pantin gate. On the Route d'Allemagne, beyond the Porte de Pantin, there is a numerous, poor, industrious population which has greatly suffered from cholera. Speaking to a poor woman in this district, one of the medical inspectors expressed the hope that she carefully boiled the Seine water which she used for drinking purposes. The answer given was a striking illustration of the true state of affairs. The woman was indignant at the question. She looked with commiseration upon the well-dressed medical inspector, who talked about sterilisation and microbes; he was evidently a very ignorant person; how could the Government employ such impracticable theorists? "Why," she exclaimed, with simple eloquence, "you do not know the price of fuel. I cannot afford enough fuel to cook my dinner properly, how am I to pay for fuel to boil drinking water?" Nor can the people living about here find, in their poverty, the time to walk a long distance to fetch a jug of pure water from the new supply organised by the Aubervilliers municipality. The people near the Pantin gate therefore continued to drink bad water, they rarely, if ever, boiled this water; and though the prevalence of cholera has decreased in this neighbourhood, the improvement is in no wise due to the new supply of water provided at Aubervilliers. Thus cholera is found to be decreasing where the Seine water is still drunk and increasing where it is not drunk.

These facts do not imply that the Seine water is a safe beverage, but they do indicate that there are other causes at work besides this poisoned water-supply. One at least of these other causes has been discovered, though very little has been said about it. A great many samples of ice have been submitted to analysis. The public were told to avoid iced drinks &c.; they have not, however, been told why ice is dangerous. The reason, I was told, was that it would cause too much alarm if mentioned in Parisian journals, but it would not have the same effect if recorded in a foreign technical paper. The truth is that on examining the ice sold in Paris some samples had been found to contain the comma bacillus. This fact, if generally known, might cause an unjustifiable panic. It would tend to empty the cafés of their usual customers, iced water being generally mixed with the drinks so largely consumed before meals. It is not because a few samples of ice were composed of contaminated water that all ice is unsafe. More important by far than this slight risk is the question as to how the comma bacillus could possibly have been found in the ice. A part of the ice sold in Paris is gathered from ponds &c. in the outskirts of the town. These are stripped of their ice during the winter months; and as the water is usually stagnant and often foul the utilisation of such ice was on general grounds declared dangerous. If, apart from such risks, the specific germ of cholera is in the ice, and if this be the ice that has been collected from ponds during the winter, then does not this show that the germ of cholera was here long before the month of April? Indeed, it is now very generally admitted that in all probability there were cases of cholera some time before April 5th, the date of the first officially recognised case at Nanterre. If the Seine water was the cause of the epidemic in the prison of Nanterre, somebody or something must have first contaminated the Seine water. The presence of the comma bacillus in ice is a suggestive indication of this previous contamination. This is a clue that should be carefully followed up.

A great deal is now being said about the system of drainage in Paris. The cholera epidemic has been seized upon as a pretext to advocate the continuation of the cess-pool system. The Seine, we are told, is contaminated because some houses drain directly into the sewers, and the sewers have their outfall in the river. Already, however, one-third of the sewage is utilised for the irrigation of the market gardens on the plain of Gennevilliers. In time it is proposed to throw the other two-thirds on the plains of

Achères and of Méry. Then Paris will no longer contaminate the Seine. In the department of the Seine et Oise, where these new sewer farms are to be created, the landowners and others are up in arms against the scheme. The subject has become a rallying cry at all local elections, and the rival political parties vie with each other in the zeal they display in resisting the project. Thus, as soon as the National Assembly meets, the Radical Deputy of the district, M. Hubbard, is to interrogate the Government in a manner hostile to the drainage scheme. The Moderate or Right Centre Deputy of the same department, not to be outdone, proposes also to interrogate the Government in the same sense. Fortunately M. Loubet, the Premier and Minister of the Interior, is a very competent authority on this subject; and M. Émile Trélat, Deputy for the fifth arrondissement of Paris, has a third question on the subject, but framed in a style which, while friendly to the project, will give the Prime Minister an opportunity of defending the drainage scheme which is now being gradually carried out.

Of course everybody is agreed that the sewage of Paris should not fall into the Seine. Most persons also think that the proposed extension of the main sewer from Paris to the sea is impracticable. There consequently remain only two solutions of the problem. The one is to keep the sewers pure from soil and to allow only rain water and slop water to enter. This is the old system, and involves, of course, the continuance of the cesspool nuisance. The other solution of the difficulty known as *tout à l'égout*, and advocated with so much skill by the late M. Durand Claye, consists in the introduction of the English method of water carriage drainage, with properly ventilated and flushed closets, and the utilisation of the sewage resulting at Achères and elsewhere, as is already in part done at Gennevilliers. But in carrying out this project the numerous industries that now flourish on the emptying of cesspools and the manufacture of human guano would come to a natural end. Hence the resistance against the irrigation scheme is not altogether theoretical; there are large financial interests at stake, and it is not unreasonable to suppose that financial support has been forthcoming in the present agitation in favour of maintaining the cesspool system. It is argued that what now goes into cesspools contaminates the river if thrown into the water and contaminates the soil if used for agricultural purposes; that cholera will become endemic in the neighbourhood of Paris if these sewage farms are allowed and epidemics will break out afresh at every dry season. Therefore houses should drain into cesspools, the contents of the cesspools should be removed, treated chemically, sterilised in the process and converted into innocuous manure. If, however, the contents of the cesspools are so dangerous, and must be so carefully removed and treated by chemical process, and all this, not for financial advantages, but for the preservation of public health, how is it that more care is not shown in the emptying of cesspools in the neighbourhood of Paris?

This brings me back to the probable causes of the present cholera epidemic. In Paris the authorities are opposed to the cesspool system, but are determined while it lasts that it shall be carried out in the best possible manner. For this purpose there are forty inspectors appointed by the town. One of these inspectors is present every time a cesspool is emptied. He calculates how many cubic metres of material is withdrawn from the cesspool, keeps a record of where it is to be taken, inspects the cesspool, sees that it is water-tight and ventilated. Wherever a case of cholera has occurred the cesspool has at once been emptied, even though it may have been cleaned out only a few days previously. Disinfectants are thrown in. The municipal inspector often enters the cesspools to examine their walls and see that there is no leakage. It is a notable fact that none of these men have been ill, in spite of their apparently dangerous occupation. As a result of this active surveillance it is known that last year, for instance, 1,172,916 cubic metres of matter were extracted from the Paris cesspools. Now follows an important calculation which may have a direct bearing upon the cholera epidemic. If the amount of soil taken from the cesspools or *tinnettes filtrées* be divided by the 365 days of the year a total of 3200 cubic metres of night soil per day is found. If this be again divided by the population of Paris the answer is almost correct theoretically—namely, 1 kilo 260 grammes per inhabitant; but one in twenty of the population do not drain into cesspools or pails, therefore there is a margin of difference between practice and theory. The important fact is, however, fully demonstrated—namely, that the soil taken out of the Paris cesspools corresponds in amount with the number of inhabitants.

If, on the other hand, one proceeds from Paris to the suburbs—the very suburbs where cholera has for so long prevailed—a totally different result is found. The population of the eight cantons which constitute the department of the Seine amounts to 616,539. Calculating on the basis of 1 kilo 260 grammes per person, there should be a daily yield of 778 cubic metres or 283,970 cubic metres of night soil per annum. The entries made at the dépôts, where the night soil is brought from the suburbs, only record a total of 147,490 cubic metres of soil received in the course of the year. Thus for the suburbs of Paris there are 136,480 cubic metres of soil unaccounted for. What has become of this enormous quantity of foul matter?—and the quantity is only estimated on the census return of the population. No account is taken of the large number of Parisians and others who visit these suburbs on Sundays and holidays. At St. Maur, on the Marne, for instance, it sometimes happens on a fine Sunday that there are 100,000 persons there, though the stationary population is about 18,000. The explanation is simple. The cesspools are not properly emptied. The distances are so great that it is not worth while sending extra carts when there are not sufficient to fully empty the cesspool. Therefore, a certain portion of the contents of the cesspools is emptied into the sewers, thrown direct into the river if the river is close at hand, or scattered on the soil round about. In any case, and whatever is done, the fact remains that annually more than 136,000 cubic metres of the foul soil, extracted from cesspools are surreptitiously disposed of, and this in a manner not likely to conduce to public health. The advocates of the cesspool system say it is dangerous to drain into sewers or to throw crude sewage on to the soil; what, however, has been done annually with these 136,000 cubic metres of night soil? The fresh unfermented soil which daily flows into the sewers, where the *tout à l'égout* is practised, is not to be compared for a moment with the concentration of foulness held fermenting for months in a cesspool. If the contents of cesspools have been thrown directly into small local village sewers, have been thrown directly into the river or on the ground, and if, to economise the trouble of emptying, some of these cesspools have been allowed to leak, then it is not surprising that the suburbs of Paris, where such abominations are the daily practice, were the first to suffer from cholera. Nor need the Seine be contaminated to produce the epidemic. It is easy to understand that the ice from ponds should have been contaminated long before any suspicion was cast on the Seine. There are wells also in the suburbs of Paris. It is bad enough that these wells should be near cesspools, but if 136,000 cubic metres of the contents of these cesspools are scattered about, the cesspools need not leak for the wells to be poisoned. It must be borne in mind that when the epidemic broke out at the Nanterre prison the Seine water, which the prisoners drank, was examined and found to contain 39,000 microbes to the cubic centimetre, but no pathogenic microbe was recognised. The cesspools then, rather than the Seine water, may have been the principal cause of the outbreak in the suburbs of Paris. In any case, a very strict inquiry should be instituted to ascertain what has become of the missing 136,000 cubic metres of soil from the cesspools in the suburbs of Paris. It would be curious indeed, though not improbable, if it could be shown to those who advocate the continuance of the cesspool system that it was precisely the contents of the suburban cesspools which contaminated the ice, the well water, and perhaps the Seine, which became the principal vehicle that spread the cholera.

With respect to the outbreak of cholera in the suburbs of Paris, and whatever may have been its cause or origin, there is one aspect of the question which seems very inconsistent. Why were the patients suffering from cholera brought into Paris? Belgians, fugitives from France, introduced cholera at Jumet, near Charleroi. Another epidemic has broken out at Pâturage, near Mons. When I was at Jumet the brick-makers, who had fled from the neighbourhood of Paris because of the cholera, informed me that a considerable number of their fellow countrymen lived near Mons, and had also returned home because of the epidemic. It is, therefore, probable that the cases of cholera at Pâturages, Wasmes &c. have been brought there by fugitives, and that we have near Mons a repetition of what occurred at Jumet, Roux, and other places in the neighbourhood of Charleroi. At Antwerp we have seen that it was the *St. Paul* from Havre which brought the cholera. The cholera in Belgium is imported from France, yet the French take precautions against this their own cholera, so to speak. The cholera by crossing the Belgian frontier did not mat-

rially change in its characteristics, yet travellers from Belgium are subjected to medical examination and surveillance when they are in a perfect state of health. On the other hand, persons dying from cholera are transported from the suburbs of Paris, where there are open fields, plenty of open air and space for isolation, and brought into crowded parts of the town of Paris. For instance, the Hôpital Beaujon, in the Faubourg St. Honoré, has received a considerable number of cholera cases. It is surrounded by hotels and dwellings on all sides. The dead from the hospital are brought out into the Rue de Courcelles in the midst of a fashionable neighbourhood. Other hospitals are in poverty-stricken districts, and there the danger is greater on account of the dirt, overcrowding and misery that exist in these localities. Many of these hospitals are old, badly-built structures, erected at a time when the knowledge of sanitation was limited. The attendants on the cholera patients frequented the neighbourhood, went into shops, sat at cafés, &c. Had these nurses and other persons taken all the necessary antiseptic precautions? A circular was issued at the commencement of July indicating what precautions should be taken, but the Paris hospitals had been receiving patients suffering from cholera ever since the month of April. The communes outside Paris have no hospitals, with the exception of the commune of St. Denis. They have consequently a treaty with the municipality of Paris according to which they pay a certain sum for all patients sent to the Paris hospitals. This is a reasonable arrangement, though from a sanitary point of view the reverse would be preferable. Instead of throwing into the crowded streets of Paris all the patients from the suburbs, it would be better if the hospitals were outside Paris and all the patients were sent to the less crowded suburbs. The bringing of small-pox and scarlet fever patients into Paris from the suburbs is a serious grievance; but at present people are only thinking of cholera, though less infectious. Surely it would have been more practical and more logical instead of taking precautions against the French cases of cholera that have crossed the Belgian frontier to have sent ambulance tents to the suburbs of Paris and have treated the cases in the suburbs where they occurred. Now that everyone is inquiring why the cholera has spread in Paris those who still believe the disease to be infectious will certainly blame the hospitals that received so many suburban cases. Even if the cholera is only contagious it is probable that the antiseptic precautions were not very rigorously applied during the first month or so.

The circular issued on this subject, and which is dated July, states that all persons entering the cholera wards must wear a blouse, fitting tight round the wrist and neck, which must be removed on leaving the cholera wards and disinfected at least once in twenty-four hours. All the attendants, nurses &c. must wash their hands and carefully clean their nails in a solution of sublimate before eating, and must take their meals apart from all the other persons employed in the hospital. Within the last week it has been further ordered that goloshes must be worn in the cholera wards, taken off and washed in sublimate at the door on leaving the wards. These are good precautions; but most persons would have preferred the establishment of tents, barracks or cottage hospitals in the affected suburbs.

The number of cholera patients treated in the Paris hospitals was 57 on Aug. 1st, 108 on Aug. 25th and on Sept. 5th there were 329. This was the maximum. On Oct. 1st there were 187 cholera patients in the Paris hospitals, and out of this number 39 came from the outlying suburbs. Looking over the list of these patients, without making any calculation but simply judging by a glance, it is impossible not to be impressed by the great number of washerwomen who have contracted the disease. The returns are as yet very incomplete, and in many cases the occupation of the patient is not mentioned; nevertheless, it can even now be said that, as compared with other occupations, washerwomen are proportionately the greatest sufferers. This is an important and instructive fact, and fully confirms the necessity of disinfecting all soiled linen. It also shows that a great deal of cholera has escaped the notice of the authorities. If the regulations were invariably applied washerwomen would be especially subject to contamination, for all the soiled linen would be disinfected. Of two things, one, either cases of cholera have been concealed and linen sent to the wash without proper precautions, or else linen can be soiled in such a manner as to convey cholera without the wearer of the linen being himself aware that he is suffering from this

disease. I also noticed in the list of patients a considerable number of domestic servants, and it occurred to me, just as a passing suggestion, that the cleaning of boots is perhaps not altogether a safe occupation in times of cholera epidemic. A certain number of persons have been suddenly attacked in the open street. Patients have been picked up after vomiting on the pavement and conveyed to the hospital. Other persons who enter rooms where there are cholera patients tread on the dejections and then walk out into the streets. The wearing of goloshes in hospital wards seems, therefore, a justifiable precaution. It will, at all events, be most useful to carefully record and study the professions and occupations of the persons who suffer from cholera.

#### A VISIT TO THE CHOLERA WARDS AT THE HÔPITAL NECKER.

Our Paris correspondent writes:—

"A few days ago I spent an instructive hour amongst the cholera patients now under treatment in a special block of buildings situated in the grounds of the Necker Hospital. This service is directed by Professor Peter, who, by the way, is to occupy the chair at the approaching dinner of the Continental Anglo-American Medical Society, and I am bound to testify to the air of comfort reigning in the two wards of which the service is composed and to the devotion and cheerfulness of the very polite *personnel*. I found that twenty patients were actually under treatment, and I was informed that five fresh cases had been admitted during the last twenty-four hours, and that three had died during the same interval of time. The first case was admitted on June 7th, and since then 152 persons had been admitted. Of these fifty (about a third) had died. None of the *personnel* had been attacked by the disease. It was curious to see in both wards—and very clean and airy they were, too—sufferers of both sexes in adjacent beds. Almost all were doing well. One man only presented the ghastly *facies* peculiar to the disease. I refer more particularly to the sunken orbits, and his voice was still broken. Another man was vomiting. In the ward devoted to convalescents the occupants, the female portion of which was considerably more aged than the male, were busily engaged in discussing with evident relish in most cases a meat lunch. The temperature of all the patients is taken regularly in the rectum. The lowest observed during the present epidemic was 78° 8' F. (26° C.); after the death of the patient the temperature reached 39° C. (103° F.). Before I refer to the mode of treatment pursued at Necker I may mention that one of the nurses, who had served in cholera wards during the outbreak of 1884, told me that at that time the patients were invariably given an emetic as a preliminary to other therapeutical measures. The treatment actually followed is as follows:—A patient admitted during the stage of collapse is at once vigorously rubbed with turpentine, and hypodermic injections of caffeine and ether are given. The sufferer is then placed in a mustard bath at from 36° C. to 38° C., and kept in for about a quarter of an hour. Replaced in bed, a Chapman's spinal ice-bag is adjusted along the vertebral column. Directly the power of swallowing is regained a mixture composed of lactic acid, syrup and water is given and preserved with white the stools, which are regularly tested with litmus-paper, yield an alkaline reaction. The spinal ice-bag is renewed every two or three hours, its employment being continued until the kidneys resume their functions, this event being almost always synchronous with the cessation of the diarrhoea. A trial was being given to strychnine administered hypodermically in doses of one milligramme, but their experience of its effects have been too limited to allow them to judge of its merits. I interrogated the patients very closely on the effects of the spinal ice-bag. All, without exception, testified to the relief afforded by it, the cramps being arrested and a feeling of warmth being imparted. Asked if it appeared to exercise any beneficial influence on the vomiting and the diarrhoea, they were not so affirmative in their declarations. As a rule the patient begins to micturate in about thirty-six hours after admission, but only one woman attributed this effect to the use of the ice-bag. It must not be forgotten that ice *ad libitum* is given to suck, and that paregoric and champagne are prescribed against the diarrhoea and collapse respectively. My *confrère*, Dr. Chapman, whose enthusiasm for the ice-bag treatment is well known, assures me that better results would be obtained were the application of cold along the spine trusted to, to the exclusion of opium, which drug he condemns utterly in cholera therapeutics."

CHOLERA IN AUSTRIA.

Our Vienna correspondent writes :—

“Whilst the progress of the cholera in Galicia has so far been very much restricted, an outbreak occurred at Budapest on Oct. 2nd. The Hungarian authorities attempted to conceal the fact of the outbreak of the disease as long as possible, although the first cases of cholera arose on Sept. 26th. At this date two fatal cases with suspicious symptoms were declared at the post-mortem examination made by Professor Schouthauer to be due to cholera Asiatica. Nevertheless the official announcement of the outbreak was kept back by the municipality until the 2nd inst., and no measures were taken to prevent the dissemination of the disease, which is said to have been imported from Hamburg by animal hides. The first cases occurred among railway-workers in a very poor suburban district. More than fifty cases of Asiatic cholera have now occurred at Budapest, according to the official report, but the real number will certainly be larger, as the disease has already appeared in different quarters of the town. The greatest negligence regarding sanitary provisions prevails in this unfortunate town, where the local authorities spend the time and the money of the taxpayers in political matters and ornamental buildings, giving but slight attention to sanitary improvements which the town sorely needs, such as a good system of sewage disposal and a good supply of drinking water. At the present time the water is taken from the Danube—a river which is being daily more and more polluted by the numerous factories erected on its banks and by the rapidly growing population of its towns. As at Hamburg the municipal authorities declared that it was impossible to be sure that the early cases were Asiatic cholera, as the bacillary cultures failed on account of the melting of the gelatine. But early in last week cultures of comma-bacilli had to be sent to Budapest from a Vienna bacteriological institute, apparently for the purpose of making comparisons. According to communications received there are no provisions made for transport and nursing a larger number of cases at the hospitals, and new barracks will have to be built. The behaviour of the municipality of Budapest this year only reproduces its attitude at the last cholera epidemic in 1886, when the public were first informed of the existence of

a cholera epidemic by a letter sent by the well-known bacteriologist, Professor Babes, now at Bucharest, to the daily papers. It cannot be said that any sanitary improvements have been made during the last six years, while the population has become considerably more dense. Magnificent palaces have been erected in the central parts, but the housing of the poor remains as bad as it was before. During the epidemic of 1886, 996 cases of Asiatic cholera, 98 cases of cholera nostras and 265 cases of “cholera” were reported, in which death occurred in 586 cases, giving a total mortality of 44.09 per cent. It must, therefore, be assumed that the cholera nostras and “cholera” cases were really Cholera Asiatica, and it would be well to accept with caution the official cholera statistics now being published at Budapest.”

SOCIETY FOR THE STUDY OF INEBRIETY.

A QUARTERLY general meeting of this Society was held on Tuesday last in the rooms of the Medical Society of London, the President, Dr. Norman Kerr, in the chair. The chairman called attention to the recent articles and correspondence in the *Daily Telegraph* and the work of the departmental committee now sitting to inquire into the best mode of dealing with inebriates as hopeful signs of the speedy enactment of compulsory legislation.

Dr. H. W. Williams, in a paper on the Urgent Need for amended Legislation for Inebriates, based this plea on three considerations—1st, as regards the inebriates themselves; 2nd, as regards their families and relatives; 3rd, as regards their neighbours and society at large. He contended that inebriety was a disease requiring medical and hygienic as well as mental and moral treatment. Many inebriates were so diseased that the efforts to control them had been paralysed, and they must have a lengthened residence in a home for a prospect of cure. As their will had been broken down compulsory seclusion was called for in their own interest, as well as for the protection of the relatives and the community from the nuisance and peril of a practical madman.

THE PUBLIC CARE OF FEVER IN 1892.

ACCORDING to the last statement of Mr. Mann to the Metropolitan Asylums Board 831 patients had been admitted to the hospitals in a fortnight, as compared with 862 in the preceding two weeks, with 370 in the corresponding week of 1891 and with 529 in the corresponding week of 1892. The notification system is developing apace and it is well to note the tendency of it. Already a third of all the cases of the notifiable diseases are admitted into the hospitals of the Board, without any inquiry as to need or the impossibility of care and isolation at home, to be housed and treated at the public expense. The following return, for which we are indebted to Mr. Mann, shows the number of cases of infectious disease notified to the Asylums Board under the Public Health (London) Act, 1891, and the number of scarlet fever, typhus fever, and enteric fever and diphtheria cases admitted into the Board's hospitals during the nine months ended Sept. 30th, 1892:—

the different diseases admitted to the hospitals. Thus of scarlet fever cases 48.68 per cent. are sent to the hospitals; of typhus fever 52.94 per cent.; of enteric fever only 27.34; of diphtheria 30.74; of the admissible diseases of the notifiable group much more than a third are admitted—to speak exactly, 43.4 per cent. The returns for the last fortnight, with previous ones, go to show the early age of the majority of the patients—thus patients aged from 1 year to 15 years comprise 90 per cent. of the entire admissions between Jan. 1st and Sept. 29th. It may seem a slight burden to impose on the State the care of all this sickness, but we cannot help thinking that it has been done somewhat thoughtlessly. By a mere stroke of the pen a clause is inserted in an Act affecting hospitals originally meant for paupers, to the effect that the Managers, subject to such regulations and restrictions as the Local Government Board prescribe, may admit any person who is not a pauper, and that the expenses incurred by the Managers for the maintenance of such persons shall be paid by the boards of guardians. We do not say that this is wrong, or that there are not some strong State reasons for it; but we should like the operation of the system

	Scarlet fever.	Typhus fever.	Enteric or typhoid fever.	Diphtheria.	Total.	Small-pox.	Relapsing fever.	Membranous croup.	Continued fever.	Cholera.	Erysipelas.	Puerperal fever.	Total.	Grand total.
Number of cases notified ..	17,004	17	1000	5300	24,710	344	6	300	105	45	4330	220	5446	30,105
Number of cases admitted ..	8,614	9	440	1600	10,723	—	—	—	—	—	—	—	—	—
Percentage of admissions on notifications .. .. .	48.08	62.04	27.34	30.74	—	—	—	—	—	—	—	—	—	—

It is probable that anxiety with regard to the risk run by other children or business considerations induce some parents to send their children when suffering from infectious diseases to the hospitals. It is curious to notice the different degree in which such motives operate in the case of

to be well considered, and we should be glad to learn what are the restrictions which have been prescribed by the Local Government Board. If there are none, and there are to be none, the hospitals now built will soon be altogether inadequate to the needs of London.

## IDIOT ASYLUMS: THE NEED OF MORE ASYLUM ACCOMMODATION.

At the annual meeting of the subscribers to the Royal Albert Asylum, held on the 30th ult., a favourable report was presented of the general affairs of the institution. The statement of the medical superintendent, Dr. Shuttleworth, however, contained particulars which to our readers will be of more general and collateral interest than mere financial considerations, though these are, of course, far from being unimportant. Thus we find that the average number of residents of the asylum during the past twelvemonth had been 581, whilst the aggregate number under care and training at some portion of the year was returned as 658. The number of discharges had been 35 and of deaths 18—a death-rate lower than that of the previous year, which, calculated upon the average number resident, was only 3·1 per cent. Allusion was made by Dr. Shuttleworth to the want of accommodation for infectious cases. Fortunately, no epidemic had occurred during the twelvemonth, but the medical superintendent did well to point out a want which might on some future occasion serve seriously to embarrass the officers engaged in conducting the affairs of the charity. The reading of the report of the central committee gave occasion to the Bishop of Carlisle, who presided, to offer a remark on the distinction between the words *amentia* and *dementia*—a distinction not always noted by the general public or by those who take an interest in such-like charities. The Bishop thought that the two classes of unfortunates ought, in all institutions intended for their treatment, to be separated. The speech of the day, however, was that of the Right Hon. J. T. Hibbert, M.P. This gentleman, whilst endorsing the text, so to say, of the previous speaker, suggested that it would be a good thing if the title of such charities were changed from asylums for idiots to asylums for feeble-minded people. Such a change, however, would, he thought, not be easy to effect, though the sympathies of parents would no doubt be with those who desired such an alteration to be made. Mr. Hibbert adverted to the difficulty of obtaining authentic statistics of the extent to which idiocy prevails in the United Kingdom. Families in which such afflicted ones are found are naturally desirous as much as possible to conceal the fact. The last census return—he had not yet been able to obtain the return of 1891—gave something like 41,000 as the number of the imbecile class, but that number ought, the speaker thought, to be at least doubled. Of the 41,000 imbeciles so returned 13,456 were believed to be under twenty years of age; in other words, they had that number of trainable idiots to provide for, whilst accommodation was secured for only something like 3000 patients. In this respect America was far ahead of this country, for in the United States no less than fourteen asylums existed for the purpose of housing and treating persons belonging to the afflicted class in question, some of these institutions being provided by the States in which they were established, others being founded and endowed by private beneficence or corporate grants. Surely the lack of adequate provision in our own country for the mental and physical wants of the weak-minded is a reflection on the philanthropic spirit of the age.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6072 births and 3236 deaths were registered during the week ending Oct. 1st. The annual rate of mortality in these towns, which had declined in the preceding four weeks from 19·8 to 17·2 per 1000, further fell last week to 16·6. In London the rate was only 15·2 per 1000, while it averaged 17·5 in the thirty-two provincial towns. The lowest rates in these towns were 7·4 in Croydon, 10·5 in Portsmouth, 11·2 in Brighton, and 12·1 in Bristol; the highest rates were 21·4 in Manchester, 21·5 in Preston, 21·8 in Salford, 21·9 in Hull, and 23·5 in Blackburn. The 3236 deaths included 533 which were referred to the principal zymotic diseases, against numbers declining from 989 to 607 in the preceding four weeks; of these, 252 resulted from diarrhoea, 81 from diphtheria, 61 from measles, 57 from scarlet fever, 46 from "fever" (principally

enteric), 34 from whooping-cough, and 2 from small-pox. The lowest death-rates from these diseases were recorded in Bolton, Newcastle-upon-Tyne, Gateshead, and Bristol; and the highest rates in Leeds, Sunderland, Hull, Salford, and Preston. The greatest mortality from measles occurred in Birkenhead, Oldham, Leicester, Huddersfield, West Ham, and Salford; from scarlet fever in Preston; from whooping-cough in Norwich and Swansea; from "fever" in Preston, Plymouth and Sunderland; and from diarrhoea in Wolverhampton, Blackburn, Sunderland, Leeds, Hull, and Preston. The 81 deaths from diphtheria included 50 in London, 5 in West Ham, and 4 in Liverpool. Two fatal cases of small-pox were registered in Halifax, but not one in any other of the thirty-three large towns; two cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 6 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3514, against numbers increasing from 3052 to 3477 on the preceding six Saturdays; 369 new cases were admitted during the week, against 349 and 370 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 114 to 152 in the preceding four weeks, further rose to 171 last week, but were 43 below the corrected average. The causes of 50, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Nottingham, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Oldham, and Hull.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the preceding four weeks from 15·7 to 17·9 per 1000, declined again to 17·1 during the week ending Oct. 1st, but was 0·5 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12·6 in Leith and 14·5 in Edinburgh, to 18·8 in Aberdeen and 22·3 in Perth. The 475 deaths in these towns included 24 which were referred to diarrhoea, 18 to measles, 17 to scarlet fever, 10 to diphtheria, 8 to "fever," 7 to whooping-cough, and not one to small-pox. In all, 84 deaths resulted from these principal zymotic diseases, against 70 and 77 in the preceding two weeks. These 84 deaths were equal to an annual rate of 3·0 per 1000, which was 0·4 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhoea, which had increased from 24 to 27 in the preceding three weeks, declined again to 24 last week, of which 12 occurred in Glasgow and 6 in Dundee. The deaths from measles, which had been 12 in each of the previous two weeks, rose to 18 last week, and included 10 in Edinburgh. The 17 fatal cases of scarlet fever showed a further increase upon the numbers recorded in recent weeks; 12 occurred in Glasgow, 2 in Edinburgh, and 2 in Perth. The deaths referred to diphtheria, which had been 7 and 3 in the preceding two weeks, rose again to 10 last week, and included 6 in Glasgow and 2 in Edinburgh. The 8 fatal cases of "fever" exceeded by 2 the number in the preceding week, and included 5 in Dundee. Of the 7 deaths from whooping-cough 6 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 71 and 66 in the preceding two weeks, rose again last week to 80, and exceeded by 14 the number in the corresponding week of last year. The causes of 45, or more than 9 per cent., of the deaths in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the preceding three weeks from 28·3 to 19·7 per 1000, rose again to 21·5 during the week ending Oct. 1st. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 23·1 per 1000, the rate for the same period being 17·1 in London and 16·1 in Edinburgh. The 144 deaths in Dublin during the week under notice showed an increase of 12 upon the number in the preceding week, and included 20 which were referred to diarrhoea, 2 to "fever," 1 to measles, 1 to scarlet fever, 1 to whooping-cough, and not one either to small-pox or diphtheria. In

all, 25 deaths resulted from these principal zymotic diseases, equal to an annual rate of 3·7 per 1000, the zymotic death-rate during the same period being 2·2 in London and 3·3 in Edinburgh. The fatal cases of diarrhoea, which had declined from 28 to 15 in the preceding three weeks, rose again to 20 last week. The deaths referred to different forms of "fever," which had been 4 and 2 in the preceding two weeks, were again 2 last week. The 144 deaths registered during the week under notice in Dublin included 30 of infants under one year of age, and 40 of persons aged upwards of sixty years; the deaths of infants showed a considerable decline from those recorded in recent weeks, while those of elderly persons showed an increase. Three inquest cases and 2 deaths from violence were registered; and 38, or more than a fourth, of the deaths occurred in public institutions. The causes of 15, or nearly 11 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

### MOVEMENTS OF MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel McD. Cuffe has been transferred from Canterbury to Colchester. Brigade-Surgeon-Lieutenant-Colonel O'Farrell, retired pay, has been appointed to the Medical Charge at Leicester. Surgeon-Captain Blackwall has been transferred to Hounslow for duty. Surgeon-Major Gubbins has resumed duty at Woolwich. Surgeon-Captain Donegan has obtained leave from Madras. Surgeon-Captain Greig and Surgeon-Lieutenant Crawford have rejoined at Aldershot, and Surgeon-Captain Windle at Chester. Surgeon-Captain Johnstone has resumed duty at Leith Fort and Surgeon-Captain Will at Piershill. The following Surgeons on Probation, who were successful at the August examination, have arrived at Netley for study:—C. E. Pollock, W. Taylor, Berryman, W. Longhurst, Rivers, F. Symons, Samman, F. Buswell, F. Manyon, and Farmer. Surgeon-Captain Hickson has joined in Dublin for duty and Surgeon-Captain Baylor at Cork. Surgeon-Major Feltham has taken up duty at Pembroke Dock. Surgeon-Major Venour, retired pay, has been appointed to the Medical Charge at Penally. Surgeon-Captain Woods has been transferred from Portsmouth to Alderney. Surgeon-Major Bolster has embarked for India. Surgeon-Captain C. R. Tyrell has succeeded Surgeon-Captain W. G. A. Bedford in command of B Company of the dépôt at Aldershot. Surgeon-Lieutenant-Colonel T. Macartney, M.D., has arrived home from Gibraltar.

### INDIAN MEDICAL SERVICE.

Surgeon-Major J. W. H. Flanagan, Medical Staff, in medical charge Station Hospital, Kamptee, has been appointed to the medical charge Station Hospital, Aden. Surgeon-Major A. E. J. Croly, Medical Staff, from general duty, Poona, to the medical charge Station Hospital, Kamptee. Brigade-Surgeon-Lieutenant-Colonel G. Thomson has been appointed Principal Medical Officer, Peshawar District. Brigade-Surgeon-Lieutenant-Colonel J. R. Greenhill, Medical Staff, will proceed home for retirement in January next. Surgeon-Colonel C. H. Y. Godwin has been appointed an Administrative Medical Officer in Bengal. The following officers of the Army Medical Staff have been selected to return to England during the ensuing trooping season, on completion of their tour of service in India:—Brigade-Surgeons-Lieutenant-Colonels H. S. Muir, M.D., R. H. Carew, D.S.O., G. J. H. Evatt, M.D., and W. McWatters; Surgeon-Lieutenant-Colonel M. D. O'Connell, M.D., in exchange with Brigade-Surgeon-Lieutenant-Colonel W. S. M. Price; Surgeon-Lieutenant-Colonel H. H. Stokes, M.B.; Surgeon-Captains N. Manders, G. Cree, H. Carr, M.D., C. H. Melville, M.B., B. L. Mills, M.D., G. S. Cardew, M.B., J. B. Wilson, M.D., J. Kearney, M.D., F. A. Saw, M.B., F. W. G. Hall, M.B., A. Kennedy, H. P. G. Elkington, T. G. Lavie, W. R. D. Crooke, M.D., W. P. Squire, C. P. Walker, M.B., and W. Downman. Surgeon-Captain C. R. M. Green, Officiating Resident Surgeon, Eden Hospital, has been appointed to act as Health Officer of the Port of Calcutta during the absence of Mr. W. Forsyth. Mr. V. L. Watts will officiate as Civil Medical Officer of Burdwan. Surgeon-Captain M. B. Braganza, I.M.S., joined his appointment in the 30th Bombay Infantry (3rd Belooch Regiment) at Loralai. The services of Surgeon-Major A. F. Sargent, I.M.S., 3rd Regiment Bombay Light Infantry, have been placed at the disposal of the Government for employment in the Civil Department. Surgeon-Captain J. P. Barry, M.B., has been appointed

Superintendent of Matheran on the expiration of the term of office of Surgeon-Major J. S. Wilkins, D.S.O. Surgeon-Major K. R. Kirtikar, Civil Surgeon, Tanna, acts as Superintendent of the Tanna Gaol, in addition to his own duties, during the absence on privilege leave of Mr. W. W. Wellis. Brigade-Surgeon G. W. McNulty, M.D., Army Medical Staff, will be retired on October 6th on superannuation. Brigade-Surgeon-Lieutenant-Colonel Hughes, Civil Surgeon, Poona, has been appointed to officiate as Principal Medical Officer, Bombay District. Honorary Surgeon W. McEvoy, Bombay Volunteer Rifles, has proceeded on six months' leave to Europe on medical certificate. Surgeon-Captain G. E. Fooks, Indian Medical Service, has been permitted by the Secretary of State for India to return to duty. Surgeon-Lieutenant-Colonel John Edward Charnock Ferris, 1st Bengal Cavalry, will retire from the Service.

### DEATHS OF INDIAN MEDICAL OFFICERS.

Surgeon-Major W. H. Cole, 3rd Dragoon Guards, at Murree, of cholera; Surgeon-Captain M. Fowler, Army Medical Staff, at Murree, of cholera; Surgeon-Major F. S. Dimond, 3rd Dragoon Guards at Murree; Surgeon-Major H. Harc, 2nd Battalion Royal Munster Fusiliers, at Cawnpore.

Arrangements have been made for appointing the Presidency Surgeons and the Civil Surgeons in the mofussil as Inspectors under the Indian Factory Act to carry out the sanitary provisions of the Act. Rigid rules for sanitary inspection have, it is said, been drawn up by the Government of India.

### NAVAL MEDICAL SERVICE.

Surgeons John Jeffreys Dinnis, M.D., and George Frederick Wales have been promoted to the rank of Staff Surgeons. The following appointments have been made:—Staff Surgeons: J. Cowley to the *Scout* and C. Macaulay to the *Castor* (both dated Sept. 30th, 1892). Surgeons: J. Thomas to the *Bellerophon*, J. L. Barrington to the *Melita*, J. Coolison to the *Ruby*, and F. Burns to the *Belleisle* (all dated Oct. 1st, 1892). Surgeon Octavius Fisher, who completed his twelve months as Medical Officer of the Plymouth Division in February last, has been appointed to H.M.S. *Impregnable*, and succeeded by Surgeon W. M. Craig, M.B. Surgeons and Agents: Henry M. Scott at Innisicrone and Pullocheny, and John J. McNulty at Derkinore and Pullendiva (both dated Oct. 5th, 1892).

### VOLUNTEER CORPS.

*Rifle*: 1st (Pembrokeshire) Volunteer Battalion, the Welsh Regiment: Surgeon-Captain G. Griffith, Honorary Surgeon-Major, to be Surgeon-Major (dated Oct. 5th, 1892).

### THE BLACK MOUNTAIN EXPEDITION.

The force which, under Major-General Sir William Lockhart, was to proceed against the refractory Black Mountain tribes has already taken the field. It is a large one, consisting of 4000 men with three batteries, in addition to a force of about 2000 strong at Durban, the base of operations. It is composed of two brigades and made up of European and Native troops. The preparations preliminary to an expedition of this nature necessarily create a great deal of work, notwithstanding the experience which the Indian officials have had of small wars of a similar nature, and the organisation of transport and medical arrangements generally must have given rise to a good deal of activity on the part of the medical service. If the Black Mountain and Wana expeditions take place and the Kurrum Valley be occupied, there will be between eight and nine thousand troops beyond the frontier.

### SURGEON IN ORDINARY TO THE LORD LIEUTENANT IN IRELAND.

Brigade-Surgeon (retired) R. F. Tobin has, as we announced last week, been appointed "Surgeon in Ordinary" to his Excellency the Lord Lieutenant in Ireland. We are glad to congratulate this officer on the appointment. Brigade-Surgeon Tobin, it will be remembered, filled the position of Assistant Professor of Military Surgery at the Army Medical School, Netley, where he did good work. He was selected to fill the post of Field-Surgeon to the Suakin expedition, where his excellent judgment and skill in operative surgery were generally recognised. He subsequently wrote an interesting report of much practical value on the surgical work performed on that occasion. In 1885 he retired from the service and was soon afterwards appointed surgeon to the St. Vincent's Hospital, Dublin, an Examiner and Member of Council of the Royal College of Surgeons, Ireland, and representative Governor of the Catholic University School of Medicine.

THE ANNUAL SANITARY REPORT OF THE PROVINCE  
OF ASSAM.

We have received a copy of the report of Surgeon-Colonel Costello, the administrative medical officer and sanitary commissioner of Assam, for the year 1891. The report deals with the vital statistics of the province and gives a brief history of the chief diseases which have affected its population during the year. The province is divided into three parts. The valley of Surma with its districts, Cachar and Sylhet, Assam proper, and the Khasi and Jaintia Hills. The total population amounts to 4,881,426. The vital statistics of the province are unreliable and are approximative only. Cholera, small-pox, fevers and the disease described by Dr. G. M. Giles, under the name of kala-azar, which is pathologically allied to the beri-beri of Ceylon, are the principal causes to the greatest mortality. We have on a previous occasion adverted to the disease known as kala-azar and its pathology. Cholera was very prevalent during the year, as it had previously been during the year 1889 in the Surma Valley, and caused great mortality. Much of the disease was attributed to importation, but the Sanitary Commissioner observes that wherever sanitation was most neglected there the cases were most numerous, and adds that a pure drinking water has been found to be the most efficacious means of ensuring freedom from cholera. Assam has a hot, damp climate and an exuberant vegetation. Its people care little or nothing for sanitation, but the tea planters might surely, if only from a selfish point of view, make things better than they seem to be on their estates.

DR. BRINSLEY NICHOLSON.

Dr. Brinsley Nicholson, who recently died at the age of sixty-eight, served in the Army Medical Service through the China War of 1859-60 and took part in the expedition to Peking. After his retirement from the service with the rank of Deputy-Inspector General of Hospitals, he devoted himself to the study of the literature of the sixteenth century, and contributed several papers to the New Shakespeare Society.

THE MILITARY RIDE.

We confess we are not at all sorry that this military ride was not received with any favour by the press of this country. No provision was made that the condition of the horses at its termination would be an important element in the matter. The ride is a purposeless undertaking from any military or scientific point of view, and, without some provision of the kind we have referred to, it is certainly not a humane proceeding as far as the unfortunate horses are concerned. Physiologically considered, it imposed relatively little strain upon the endurance of the riders, but a cruel one upon their horses. Long rides as a training for men and horses for the purposes of a campaign may find something to be urged in their favour provided they are undertaken for strengthening and developing the powers of both, but nothing of this kind entered into the present undertaking.

AMENITIES OF FOREIGN SERVICE.

In commenting recently upon the length of the foreign service tour we mentioned the fact that the number of appointments at home appropriated to officers on the Retired List made this grievance all the more keenly felt. It appears to us that if a certain number of changes were made tenable for a fixed period the grievance would be considerably lessened and the public service would be benefited. At the present moment the fixed changes are limited to the hospitals for women and children and a few other appointments. If army medical officers were guaranteed in their posts for a term of years instead of being constantly shifted about, it would be good for them and good for the army at large, and would save expense whilst reconciling them in a measure to their lengthened expatriation.

**FOOTBALL CASUALTIES.**—The following casualties occurred last week. During a match at Durham, under the Rugby rules, a Jarrow youth collided with another player and was heavily thrown. On removal to the hospital it was found his spine was seriously injured. A member, aged twenty-two, of the Thistle Football Club, Aberdeen, whilst playing in a game at Drumoak Farm, sustained a compound fracture of his left arm. In a match between the Walsall Town Swifts and West Bromwich Albion Clubs the captain of the Walsall club fractured his clavicle.—A youth aged seventeen, in a match between two junior teams at Linthorpe, Middlesbrough, fractured his left arm.

## Correspondence.

"Audi alteram partem."

### "VACCINATION AND SMALL-POX MORTALITY."

To the Editors of THE LANCET.

SIRS,—Your annotation in THE LANCET of Sept. 24th under the above heading raises a point in connexion with this controversy which I think needs emphasising. I refer to the practice of nominal or insufficient vaccination, which, while it conforms to the letter of the Act, engenders in the minds of ignorant people a false sense of security, and is therefore calculated to bring discredit on a most salutary measure. There can be no doubt, I think, that the number of those who are practically "unprotected" from small-pox is increasing year by year to a dangerous extent, and if we could include under this term only such as are "unvaccinated," our opponents would not have the grounds they now have for declaiming against compulsory vaccination. Unfortunately, however, it is only too true that numbers of persons are now growing up who can only show one or perhaps two small marks as the result of their primary vaccination, and who, when exposed to an epidemic of small-pox, will doubtless, as in the past, swell the number of those who are triumphantly cited by anti-vaccinationists as having contracted the disease in spite of having been vaccinated. These gentlemen would, however, do well to note in this respect what they seem wilfully to ignore, but what is abundantly shown by the reports of the various outbreaks of the disease which have occurred from time to time—viz., that whenever small-pox has attacked vaccinated persons the severity of the disease has been in inverse ratio to the number of marks such persons can show. This being the case, there must surely be something radically wrong with an Act which, while imposing upon public vaccinators the production of four vesicles, allows a systematic evasion of its provisions to go on unchecked; and I cannot but think that we are fast losing the advantage of protection from small-pox which that Act was framed to secure for the want of more stringent measures to ensure its efficient administration. It is notorious that at some of the public vaccination stations in our large towns the office of public vaccinator is becoming a sinecure, simply because their work is drifting into the hands of the cheap vendors of advice and medicine who, it may be, from a misplaced sympathy, encourage an evasion of the spirit, if not of the letter, of the Act which must sooner or later lead to direful results. I do not pretend to see clearly how this anomalous state of things is to be remedied; but at least it is not unreasonable to expect that if the public vaccinator has to submit to supervision of his work by Government inspectors, such supervision should also be extended to the large number of irresponsible private vaccinators who are at present quite uncontrolled. Of course, as long as the operation is in the hands of the medical profession at large it would be impossible to inspect every case, but it might at least be made compulsory to state on every certificate the number and size of the vesicles. Would not also a periodical inspection of Board schools afford some means of checking the work of private practitioners among the poorer classes? There is still the question of compulsory revaccination, but I fear I have already trespassed too much on your valuable space. I should, however, be glad to see the whole matter taken up by some of your numerous readers who may be more competent to deal with it.

I am, Sirs, yours faithfully,

Bristol, Sept. 29th, 1892.

E. H. WARNER, M.D. Edin.

### "THE NOTIFICATION OF DISEASE."

To the Editors of THE LANCET.

SIRS,—It is clear that nothing is to be expected from the medical officer of St. George's, Hanover-square, concerning the point I raised in your journal of a fortnight ago, and I do not wish to take up your space further than to make clear the point at issue. Dr. Corfield is unable to go outside the strict letter of the Notification Act, and maintains that no matter how many medical practitioners are called in to see a case of infectious disease, every one of them is bound to

notify. "As a matter of fact," he says, "if only one certifies it to the medical officer of health, the latter is quite satisfied, as he does not want more than one certificate of one case, but if neither of them certifies he is bound to report them all." But it is not a question of the *satisfaction* of the medical officer of health. The question is what is right, and the right is determined in a new Act by the administrators of that Act. Most Acts, if we abide by their letter, are in places doubtful in their meaning, or often enough absurd, and in this case I maintain that to compel three or four individuals to notify when only one certificate is required is absurd, and is not the *intention* of the Act, whatever the wording may be. I further maintain that inasmuch as the medical officers of health are the administrators of the Act they are "not bound to summon everyone who may happen to be called in to see a case of infectious disease." The one in charge of the case is the one who is responsible and none else, and the medical officers of health ought so to work the Act. How am I to know who is the medical officer in twenty or thirty parishes not my own? Moreover, I know, as I said in my former letter, that a large number of medical officers of health interpret the Act in this liberal spirit. So they tell me, and there ought to be some uniformity.

I am, Sirs, yours faithfully,

JAMES F. GOODHART.

Weymouth-street, W., Oct. 3rd, 1892.

### "GLYCOSURIA WITH LOW SPECIFIC GRAVITY OF URINE."

To the Editors of THE LANCET.

SIRS,—Dr. Nicholson, writing in your last issue, gives details of a case of this unusual occurrence, and remarks upon the extreme rarity of the condition. Possibly, if the urine were tested for sugar as a routine and not passed over with the remark, which I have sometimes heard, "Normal (or sub-normal) specific gravity, therefore no sugar" these cases might be found to be not so very rare after all. The following case was seen for the first time on Sept. 25th; it may perhaps interest Dr. Nicholson and others.

Mrs. B—, aged sixty-five, had enjoyed good health until five years ago, when she became suddenly hemiplegic and aphasic. She slowly recovered the use of her limbs, but her speech has remained much impaired up to the present time. A second similar but slighter attack occurred three years later, but she has remained fairly well and able to do her house work up till two or three weeks ago, when she had to give up on account of increasing dyspnoea. Examination showed the following:—Heart slightly hypertrophied; sounds extremely irregular both in force and rhythm; no bruit; arteries rigid and tortuous; lungs slightly emphysematous; abdominal viscera apparently healthy; ankles rather oedematous; veins of legs varicose; urine acid, sp. gr. 1020, no albumen or casts; sugar about 5 gr. in the ounce. I was surprised at these results, and at first inclined to doubt them, as there were no symptoms of diabetes, and I happened to be using for the first time the cupric test pellets introduced by Dr. Pavy; but some freshly made Fehling's solution gave precisely the same result. After three days' treatment by digitalis and diet the urine showed sp. gr. 1010, no albumen or casts, but still a trace of sugar; dyspnoea all but gone. Four days later, though the specific gravity had risen to 1015, not a trace of sugar was present.

I am, Sirs, yours faithfully,

CHARLES CLAYTON, M.R.C.S., L.R.C.P. Lond.

Broadhurst-gardens, N.W., Oct. 3rd, 1892.

To the Editors of THE LANCET.

SIRS,—The condition of urine described at p. 773 is not so extremely rare. Both in THE LANCET and other medical periodicals cases are reported with a specific gravity as low as 1005, *vide* "Medical Digest," Section 332: 1.

I am, Sirs, yours obediently,

RICHARD NEALB, M.D. Lond.

Boundary-road, South Hampstead, N.W., Oct. 3rd, 1892.

To the Editors of THE LANCET.

SIRS,—Seeing an account of a case under the above heading in THE LANCET of Oct. 1st I should like to mention the case of an old gentleman I am now attending; his age is seventy. He has the usual symptoms of diabetes as met with in elderly people: the urine contains abundance of sugar, the test used

being Pavy's method, and the sp. gr. is only 1015. Thinking that there might be some error in my manipulations I submitted a sample of the urine to a medical friend, who verified the above statements after using two urinometers. There is no albumen present.—I am, Sirs, yours faithfully,

WALTER BARBER, L.R.C.P.I

Roman-road, Bow, E., Oct. 4th, 1892.

### THE PROPAGATION OF CHOLERA.

To the Editors of THE LANCET.

SIRS,—The propagation of cholera by means of human intercommunication is a simple explanation of the extension of the disease, but the theory is not altogether satisfactory, for if it were it would be natural to expect a more frequent visitation of the disease, since the same causes which brought about the present outbreak are in constant existence. To describe cholera as a "filth" disease is to create an erroneous and misleading impression, for the utmost disregard of all the laws of sanitation will not generate cholera any more than any other disease. It is true filth naturally creates a susceptibility and that those who live amidst insanitary surroundings more readily fall victims to any prevalent disease, and therefore every epidemic might and should with equal justice be called a filth disease. Further, we are informed on the highest authority of the probability of a renewed outbreak next spring. How is this temporary abatement explained on the theory of human intercommunication? Again, this theory fails to explain how the epidemic reaches a "maximum of intensity" and then gradually declines, sometimes, however, to rise a second or even a third time. How, too, can the fact be accounted for that occasionally those who live on one side of a street are affected whilst those on the other side escape? The theory of human intercommunication lacks corroboration. As an independent observer I am convinced cholera can only exist under certain meteorological conditions, and that the poison can be, though not necessarily always is, conveyed by the winds, and I maintain that the meteorological theory offers as rational and as simple an explanation of the vagaries of cholera as the theory of human intercommunication.

I am, Sirs, yours obediently,

G. SHERMAN BIGG,

Formerly Staff-Surgeon, Allahabad, India.

Victoria-street, S.W., Oct. 3rd, 1892.

### "THE BIRKBECK PANIC: A MANIACAL EXCITEMENT."

To the Editors of THE LANCET.

SIRS,—In your issue of Sept. 24th is an annotation in which the term "maniacal excitement" is applied to the depositors who, under the influence of a scare which turned out to be unfounded, withdrew their money from the Birkbeck Bank. Will you allow me to protest against this application of a term which is a scientific one, connoting definite phenomena that were not present in the case in question, and which ought, I think, to be restricted to its true scientific meaning? By maniacal excitement, as understood in alienism, is meant excitement which (1) is in excess of what is justified by the circumstances in which the individual is placed; and (2) does not subside when the true nature and significance of the circumstances are made clear. In neither of these particulars was the excitement of the Birkbeck depositors maniacal. When they had reason to believe that the money—which in many cases was the result of the toil and saving of a lifetime—was in jeopardy a considerable height of excitement was natural and justifiable; and I do not find in the published accounts that the degree of excitement manifested was so extreme as to be in excess of what might naturally be expected of the normal or average man under such circumstances, supposing the circumstances to be as the depositors imagined. Secondly, when by the prompt payment of all claims the true nature and significance of the circumstances were made clear the excitement at once subsided. Since, therefore, neither of the qualities which are necessary to constitute the excitement maniacal was present in this case, it is, I think, to be regretted that this term should be applied to it.

I am, Sirs, your obedient servant,

CHAS. MERCIER, M.B. Lond., F.R.C.S. Eng.

Catford, Sept. 24th, 1892.

\*\* We publish Dr. Mercier's letter with pleasure. We are well aware that the removal of the cause of a disorder or

derangement will at any rate tend to the removal of the disorder itself, if it does not entirely remove it. A delusion which "subsides when the true nature and significance of the circumstances are made clear" was none the less a delusion. So may it be with other conditions where morbid mental manifestations existed, whatever names we may choose to apply to them. We are certainly not prepared to pin our faith to definitions in insanity; but as a set-off to Dr. Mercier's definition as given above we quote a definition given by the writer of the article "Mania" in Dr. Hack Tuke's "Dictionary of Psychological Medicine" just issued from the press: "Mania may be defined as being an affection of the mind characterised by an acceleration of the processes connected with the faculty of imagination (perception, association and reproduction), together with emotional exaltation, psycho-motor restlessness and an unstable and excitable condition of the temper."—ED. L.

## CENSURE OF A MIDWIFE AT WEST BROMWICH.

To the Editors of THE LANCET.

SIRS,—The *Birmingham Gazette* of August 15th last gives a short account of an inquest held at West Bromwich where a woman who had attended the unlucky subject of it was censured for not sending for a doctor, though it was allowed that she had done her best according to her ignorance. Her total incapacity to perform what she had undertaken was held to be a bar to a verdict of manslaughter, though if she had lost her patient in an attempt to remove a sloughing fibroid, for example, which nature was trying to get rid of, I very much doubt if her ignorance would in that case have been accepted as a valid excuse. There was, apparently, no medical evidence given at the inquiry, but Dr. Lawson, who was called in after death, has given me some details of the case, and he and Dr. Manley, the medical officer of health, have very kindly furnished me with some information as to the state of midwifery in West Bromwich. The patient no doubt died from post-partum hemorrhage consequent on failure to remove the after-birth; the cord was in the chamber and had evidently been torn off in an attempt to remove it by traction, but the "midwife" had refused to send for medical assistance. I learn that the town, with a population of about 60,000, "is full of women who pretend to know something" and that "the majority of the poorer classes are attended by women who are either professed midwives (not certified) or mere neighbours." "The population is very poor and they cannot all pay fees." With these facts before us that "accidents are rare" and that the mortality from puerperal fever is 2.6 per 1000 births must be looked upon as due to a fortuitous concatenation of circumstances and to the powers of the women, unless we consider that the fact of the medical officer of health knowing and to some extent supervising the "midwives," as shown by his having been directly instrumental in stopping two of them from practising, accounts for it. He considers the women now in practice to be trustworthy.

How little knowledge is required and how much a little supervision might accomplish is here sufficiently indicated, and yet what other branch of the healing art can be compared to it in respect to the trusting innocence with which it is regarded by both midwife and patient—at any rate, in West Bromwich? The administration of the domestic "Gregory's powder" or the insertion of a needle into a boil are alone on the same level. The era of obstruction and proverb which in the early part of this century ushered in the general use of the forceps is still with us. Ignorance in the use of "instruments," self-confidence in manual operations and comparative disregard for the life of the child on the side of the profession, combined with an unreasoning horror on the part of the public, long hindered the mitigating influence of the forceps; so it is at the present time ignorance as to the true state of things amongst the opponents of the Midwives Bill. In a few cases the ignorance appears to be wilful and will not be enlightened. Self-confidence as to our powers of preventing the extreme evils of ignorant midwifery, however late we are called in, forgetful as we are of the terrors and anguish sore, which in such case must precede our arrival; a belief in nature's powers, which gives rise to a passive endurance worthy of a Stoic on the part of the women, all combine to produce—

alas, how often!—a tragedy seldom equalled, except by similar cases in fact or fiction. If the indifference and carelessness of the patients of these untrained midwives could for one brief hour be swept away, how long would this want of regard for "our neighbour" exist? We know very well that the torrent of public opinion would soon put a new and healthier face on these old-standing sores. I trust that the work of the Select Committee of the late Parliament will not be allowed to waste in a pigeon-hole, only to become an interesting document for a future and wondering generation.

I am, Sirs, yours faithfully,  
Fellows-road, N.W., Sept. 20th, 1892. ROWLAND HUMPHREYS.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### Opening of the Winter Session.

THE usual opening of the Medical Faculty, Liverpool University College, with the delivery of an address and the distribution of prizes has been departed from. It was found impossible to complete the new University buildings in time, and it was therefore resolved to postpone the opening ceremony to a later date. But the lectures will all commence this week. The anatomical rooms are open, with a plentiful supply of subjects, and students are already hard at work. With the new infirmary, and the now almost completed university buildings, the local medical school is one of the most complete in the kingdom; but more space is still required in some departments and further improvements are contemplated.

### The Northern Hospital.

It is hoped that the City Council will be induced to grant a sum of money as well as a site for the proposed new Northern Hospital. The present building has for a long time past been found to be quite inadequate, and a new one is imperatively demanded.

### The Local Intra-mural Cemeteries.

On June 2nd the City Council resolved: "That the Health Committee be instructed to consider the desirability of taking steps for closing St. James's cemetery." In accordance with this the medical officer of health, Dr. Stopford Taylor, reported that the cemetery is conducted according to the regulations provided under the Burials Act, that there are no common or public graves and that no complaints have been made which would justify them in taking legal proceedings. It has been frequently inspected and no nuisance found to exist, nor has there been any evidence of injury to the health of the inhabitants in its immediate neighbourhood. Though no positive injury can be demonstrated to have arisen from it, yet the medical officer would express his entire concurrence in the resolution arrived at many years ago by the Government Commission on intra-mural interments: "that all interments in towns where bodies decompose contribute to the mass of atmospheric impurity which is injurious to public health." The Health Committee have therefore reported that in their opinion it is not at present desirable to take steps for closing the St. James's cemetery. With regard to the necropolis, an intra-mural cemetery situated on the same level as the houses by which it is closely surrounded, Dr. Taylor reported that it ought to be closed except for family graves. St. Mary's cemetery, Kirkdale, a third cemetery which has by the growth of the city passed from being an extra-mural into being an intra-mural one, is now practically closed by the Order in Council, May 10th, 1872, which limits the interments to the burial of the bodies of certain specified relatives in family vaults, walled or earthen graves, subject to strict regulations as to depth &c.

### Prevention of Cruelty to Children.

During the month of September the local society took up 78 new and 76 old cases, the former involving the welfare of 102 and the latter that of 88 children. Among the complaints were 7 cases of assaults, 1 of excessive beating, 38 of general neglect, 15 of selling when under age, 21 of begging by day, 61 of begging by night, 6 of selling at night, 23 of exposure, 11 of sleeping out, 7 of dangerous surroundings.

### Railway Passengers from Cholera-infected Parts.

A correspondent signing himself "An Eye Witness," and whose statements have been authenticated, has written in a daily paper descriptions of the very filthy condition of some Russian emigrants on their arrival at the Liverpool terminus

of the L. and N.W. Railway. Although it was possible, and even probable, that they might have come from places, infected with cholera, the medical officer has not the same powers to deal with them as he has with the crews or passengers of ships arriving in the Mersey. Still every care has been taken to prevent any ill consequences, and the number of such passengers will probably in future be very few until all danger of cholera has passed away.

Oct. 6th.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT)

### *The Mason College.*

OCTOBER 1ST was a memorable day in the history of Queen's College. The old associations of the past, the relations of the former buildings and the traditions of the medical school flourishing therein for many years have been uprooted and conveyed to "fresh scenes and pastures new" at Mason College. Not without a passing pang of regret to former students, but full of hope and aspirations for the future, the union of the two colleges has become an accomplished fact. The event had been signalled by preliminaries for some time past, and the occurrence was made the occasion of a large gathering of medical men to hear an address by Sir George Humphry. This was listened to with much interest. The mature wisdom, the ripe learning and practical sagacity, combined with an intimate knowledge of the educational wants of the profession, gave additional emphasis to the address, which called forth hearty applause from the audience. A vote of thanks, proposed by the Mayor and seconded by Mr. Oliver Pemberton, was unanimously accorded. In the evening there was a reception by the president, vice-president and principal, followed by a successful conversation, to which 2500 invitations were issued. The opening entertainments afford a good augury for the success and prospects of the union thus celebrated.

### *The Value of Exercise.*

In the opinion of most members of the medical profession judicious physical exercise is conducive to well-being and health, and its practice is generally recommended. The exception sometimes proves the rule. At a meeting of the Birchfield Harriers the ex-President of the Board of Trade—Mr. Chamberlain—remarked, "I do not cycle, I do not ride, and I do not walk when I can help it. I do not play cricket and I do not play football. I do not play tennis and I do not even play golf. The fact is that I do not take any exercise at all." At the same time the right hon. gentleman pointed out that the qualities which brought success in such pursuits are those which have distinguished Englishmen throughout the world, and which have made them the most enterprising travellers and explorers. The danger in the present day is not in taking exercise, but in the extremes to which it is sometimes pushed. When competition becomes an element there is a risk of the boundary line of health being overstepped and harm ensuing.

### *The Midland Medical Society.*

The admission of women as members of this Society was settled at the annual meeting held on the 5th inst. Among "the following gentlemen to be balloted for" there was the name of a lady practitioner. The lack of interest in the election was shown by the number present. Out of 322 members representing the Society there were ten present and four officials. The voting showed nine for and two against, and as the candidates, twelve in number, were balloted for *en bloc* they were all elected. The time has passed when the introduction of a question of this kind would have provoked a storm and led to a lively meeting.

Birmingham, Oct. 6th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *Lunacy in Northumberland and Durham.*

DR. McDOWALL has issued the report of the Northumberland County Asylum at Morpeth for the past year. This asylum, which was commenced in 1859 with about 130 patients, has now 600 patients under treatment. We have in this report the same story—namely, that the accommodation is nearly exhausted and that further extensions will have

to be seriously considered. There is no indication, Dr. McDowall thinks, of any diminution in the demand for accommodation for the insane poor; and this would seem to accord with the facts observed in the neighbouring county of Durham. For instance, we read that there is still a dispute in progress between the Sunderland guardians and the town council as to which authority shall take charge of the imbeciles at the workhouse. The corporation have orders to remove 300 patients from the vast asylum at Sedgelyield by June next, and to meet this they are building an asylum at Ryhope to accommodate 350 patients. The guardians, it appears, stand to their resolve to hand over to the corporation the imbeciles now in the workhouse as soon as the new building is finished. The number of patients for which the corporation and guardians are responsible is nearly 400, so there is certain to be a hitch again about this vexed question of accommodation for the insane. I hear that in the Newcastle City Asylum at Coxlodge the accommodation on the female side is now exhausted and that steps are in progress to enlarge the institution very considerably.

### *Death of Mr. John Russell.*

In THE LANCET of last week appeared a notice of the death of Mr. John Russell, M.R.C.S., at Worthing, at the age of sixty-two. Mr. Russell was a native of Durham city, and served his apprenticeship to Mr. Jephson, a well-known practitioner there. He afterwards passed to St. Bartholomew's Hospital, where he remained until he qualified. He came to practise in Newcastle at a very opportune period, two old practitioners at this time retiring—namely, Mr. Annandale and Dr. Bleazley. Mr. Russell very soon made rapid progress in his profession, and in an unusually short time acquired one of the best general practices in Newcastle. He was also appointed surgeon to the infirmary and lecturer on anatomy at the College of Medicine. He was a good surgeon, but always had a reluctance to operate in public. This and his large general practice kept him back in the surgical race. Mr. Russell had charming manners, and was a gentleman of great and varied information. He was very well liked by his professional brethren, and he was indeed honourable in all his dealings. His health began to fail a few years ago, and he decided to retire. He has left a grown-up family, none of whom have followed the profession.

### *The Supply of Impure Water to Durham Villages.*

In consequence of the prevalence of typhoid fever in the Easington district an analysis of the village wells was made and they were found to be seriously contaminated with sewage and other organic matters; indeed, some were shown to receive their supply through a churchyard. The overseers and several prominent householders have been summoned with a view to rectify matters. It seems now that this was a mistake in procedure, as a letter has been received from the Local Government Board stating that the rural sanitary authority was the body responsible for the purity of the water-supply and not the overseers. Orders for the closing of the impure wells have been made by the magistrates. Thirteen wells are more than suspected.

Newcastle-on-Tyne, Oct. 6th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Professor Ogston.*

PROFESSOR OGSTON'S decision to yield to the great pressure brought to bear upon him to withdraw his resignation as senior surgeon to Aberdeen Royal Infirmary has given unqualified satisfaction to the medical profession, to the students of medicine and to the general public of the north-east of Scotland. This decision was announced to the directors of the institution by the chairman at a meeting held last week.

*Aberdeen Royal Infirmary: Opening of the New Hospital by Princess Louise.*

On Tuesday, the 4th inst., Princess Louise, accompanied by Princess Beatrice and Prince Henry of Battenberg, visited Aberdeen and formally opened the new buildings of the Royal Infirmary. The principal streets and buildings of the city were profusely decorated, and special preparations were made at the infirmary, a grand stand capable of accommodating 700 people having been erected opposite the main door, where was a raised platform for the Royal party. The Aberdeen company of the Volunteer Medical

Staff corps formed a guard of honour near the platform. The proceedings commenced by the Aberdeen Madrigal Choir singing the National Anthem. Mr. Littlejohn, chairman of directors, presented an address to Princess Louise, and Prince Henry read her reply. After another hymn and a dedicatory prayer by the Rev. Mitford Mitchell, D.D., one of Her Majesty's chaplains, a silver key was presented to the Princess, who thereupon declared the building open. The medical staff were then presented to her Royal Highness, and the nursing staff presented her with a bouquet. Thereafter the Royal party made a minute examination of the wards.

#### *Health of Aberdeen.*

On Monday, the 3rd inst., the Aberdeen Town Council decided by sixteen votes to eleven to delay for three months further consideration of the proposed additions to the city fever hospital. Last week 185 cases of zymotic diseases were reported to the medical officer of health, being an increase of 71 as compared with the previous week. This large number is composed mainly of cases of measles, of which there were 130, with 42 cases of scarlet fever.

Edinburgh, Oct. 5th.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

#### *Reported Case of Cholera.*

CONSIDERABLE alarm was caused recently in Banbridge by the rumour, industriously circulated, that a farmer had died quite suddenly from cholera. An investigation, however, showed that the disease in question was not cholera, but it was thought advisable to destroy the patient's bedding and clothing.

#### *Colleges of Physicians and Surgeons: Conjoint Scheme. Five years' Curriculum.*

The following regulations will apply for the first year for candidates under the five years' curriculum:—1. Demonstrations and dissections, six months; Theoretical Chemistry, six months; Practical Chemistry, three months; Practical Pharmacy, three months; Physics and Elementary Biology may be studied before or after registration, three months. The subjects of the First Professional Examination will be Chemistry, Physics, Practical Pharmacy, Elementary Biology and Anatomy (bones with attachments of muscles and ligaments, joints). A candidate may take this examination as a whole at one time, or in four parts, but the examination in anatomy not earlier than the end of his first winter session.

#### *Dublin Main Drainage.*

In May last year a committee was formed for the purpose of instituting inquiries as to the necessity of a scheme of main drainage for the city of Dublin, and ultimately, in December, 1891, a report was adopted recommending Chatterton's scheme of main drainage. The Local Government Board also held an inquiry and approved of the suggested scheme, and an Act passed giving the sanction of Parliament to the project. The Corporation found that by charging the entire cost of that scheme and adding it to the amount of the city loans there would be scarcely any margin left for carrying out all the other schemes of equal importance, such as the building of artisans' dwellings, which were considered absolutely necessary. The late Government gave exceptional powers to get £100,000, which would not be charged under the Public Health Act to the borrowing powers of the Corporation, and the latter agreed to promote a Bill that the loan should be an exceptional one. On Monday they adopted the following resolution in reference to this matter:—

To consider and, if approved, to adopt a resolution in reference to promoting, and the expense of promoting, a Bill in the next session of Parliament for the purpose of amending, enlarging and defining the powers of the Corporation as to borrowing and application of money borrowed, and for confirming and providing for the expenditure of money on the Dublin Main Drainage and on the extension and improvement of the Dublin Corporation Waterworks, and for such other matters incidental thereto or connected therewith respectively as shall be deemed expedient, and, if approved of, to pass a resolution authorising the Corporation to proceed with the Bill, and to apply the municipal funds or rates, or some or any of them, to the payment of the costs and expenses attending the same.

#### *Meath Hospital.*

The introductory lecture on the opening of the winter session was given on Monday by Dr. L. Hepenstal Ormsby. He referred chiefly to the grievances of Irish dispensary medical officers and the exclusion of Irish diplomats from

English hospital appointments and the grievances of the Army Medical Service. You will probably, however, report the lecture either in full or in abstract.

#### *International Medical Congress, Rome, 1893.*

The following gentlemen have been nominated on the Committee for Ireland: Sir George Porter, Bart., Regius Professor of Surgery, Univ. Dublin; Sir William Stokes, Professor of Surgery, Royal College of Surgeons; E. H. Bennett, M.D., Professor of Surgery, Univ. Dublin; Samuel Gordon, M.D., ex-President Royal Academy of Medicine; W. Thomson, M.D., surgeon to Richmond Hospital; James Cuming, M.D., Professor of Medicine, Queen's College, Belfast; Henry Swanzy, M.D., Surgeon, National Eye Infirmary; J. M. Purser, M.D., Professor of Physiology, Univ. Dublin; Lombe Athill, M.D.; E. McWeeny, M.D., Professor of Pathology and Bacteriology, Cath. Univ.; C. Nixon, M.D., Professor of Medicine, Cath. Univ.; and D. Cunningham, M.D., Professor of Anatomy, Univ. Dublin.

#### *Death of a Centenarian.*

Cornelius Egan, of Dingle, county Cork, died last week at the alleged age of 120 years.

#### *Medical Magistrates.*

The Lord Chancellor has appointed Dr. Francis McLaughlin and Dr. Michael O'Kane to the Commission of the Peace for Londonderry city; also Professor Pye, M.D., of the Queen's College, and Mr. Nicholas Grealy for the city of Galway.

Oct. 4th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *Extensive Ecchymoses after an Epileptic Attack.*

At the Pau Congress of the French Society for the Advancement of the Sciences, Dr. Cabadé reported the case of a carpenter aged forty, robust and free from cardiac and vascular lesions, who, after an attack of epilepsy which occurred in bed, presented on the morrow subcutaneous extravasations of blood involving the chest from the sub-clavicular region to the base of the thorax on the right side and to the crest of the ilium on the left side. The arms and the shoulders were also enormously swollen and discoloured from the same cause, the circumference of the former being fifty-four centimetres. At the seats of the ecchymoses the skin was hard, raised and tense, and great pain was complained of in the arms and shoulders, this being probably due to compression of the brachial plexus by the effused blood. The face was not altered. The ecchymoses underwent the usual changes of colour, and it was fully two months before they finally disappeared. The patient's wife, who slept at his side on the night of the attack, heard no fall, and was only conscious of some agitation on the part of her husband. The tongue was bitten, but the temperature was normal. The man had long been subject to attacks of petit mal, and since the seizure above mentioned he has had two others of haut mal, but unaccompanied by ecchymoses. Professor Pitres of Bordeaux states that this case is unique in medical literature, and I communicate it to THE LANCET as being of possible interest to medical jurists.

#### *The Influence of an undue Consumption of Salt on the Development of Leprosy.*

The etiological importance of salt fish in the production of leprosy has been insisted on by many dermatologists, notably by Mr. Hutchinson. When years ago I accompanied the Medical Commission of Cape Colony on their visits to the leper establishment on Robben Island I found that the same idea prevailed amongst my colonial *conférrés*. Notwithstanding the prevalence of the disease amongst races who do not consume fish, and its absence in many districts where that comestible is largely eaten, the following facts cited by Dr. Azoulay at the Pau Congress appear to lend support to the hypothesis that the excessive consumption of salt (as in salt fish) may encourage the pullulation of Hansen's bacillus. A young Greek, a patient of the late Professor Darnaschino at the Laennec Hospital, and suffering from ulcerative and anæsthetic leprosy, stated that since childhood he had been in the habit of eating considerable quantities of salt, which he added to every dish he ate. Another affected with the nodular and mutilating variety of the disease made the same confession, and related how his uncle, with whom he used to inhabit an isolated hut, and

who had died of leprosy, had an inordinate appetite for salt. A leprosy patient under M. Vidal's care, whom I remember seeing at St. Louis, had by his bedside a jar of salt, of which he made free use during his meals. This patient had contracted the disease at Calcutta. Another example is furnished by a Frenchman, in whom the disease had developed during a sojourn in the province of Murcia (Spain). All the above-mentioned individuals stated that their craving for salt which they could not overcome, although fully aware of its injurious effect on their leprous troubles, was not shared by the other inhabitants of the districts where their disease had first made its appearance. Dr. Thernes said that in the Antilles, where leprosy is more frequently met with amongst the blacks than amongst the whites and the half-bloods, the former consume daily salt codfish imported from Newfoundland. M. Regnault had never noticed any particular *penchant* for sodium chloride amongst the leprous in India, but he deemed the subject worthy of investigation.

#### *The Situation of the Respiratory Centre.*

We have hitherto been accustomed to regard the integrity of a tract situated in the medulla oblongata between the vasomotor centre and the calamus scriptorius, and christened by Flourens *naud vital*, as indispensable for the continuance of the respiratory function. But Dr. Brown-Séguard has brought to the notice of his colleagues of the Académie de Sciences a series of experiments conducted by MM. Gad and Marinescoy on sixty-five dogs, rabbits and cats, which lead them to a different conclusion. These physiologists maintain that the destruction of the various centres regarded by Flourens, Gierke and Mislawsky as centres of respiration does not involve the permanent arrest of that function provided certain operative precautions be taken. They further state that there exists in the lower part of the medulla at some depth from the surface a mass of cells, the destruction of which brings about arrest of respiration, while the stimulation of the same mass determines characteristic changes in the respiratory rhythm. This region, which they are disposed to regard as the true respiratory centre, is not a clearly circumscribed zone, but is composed of a collection of nerve cells scattered on each side of the roots of the ninth nerve. The centrifugal paths along the cord are direct and occupy the anterior radicular zone.

Paris, Oct. 6th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

#### *The Cholera in Germany.*

THE numbers of cholera cases and deaths in Hamburg on the 26th ult. were respectively 70 and 33, on the 27th 58 and 42, on the 28th 70 and 42, on the 29th 33 and 24, on the 30th 47 and 14, on the 1st inst. 43 and 21, and on the 2nd 26 and 12. Professor Gaffky of Giessen, one of Dr. Koch's companions on the famous journey to Egypt and India, in the course of which Dr. Koch discovered the cholera bacillus, has been called to Hamburg to subject the new well-water there to bacteriological tests. Unhealthy dwellings in Hamburg are being emptied with all possible energy. Professor Pettenkofer recommended the rapid demolition of the "Gängeviertel" (Lane Quarter) and of the Stain Strasse, one of the most important streets of the city. London and Paris doctors arrived at Hamburg about the end of last month to study cholera in the barrack hospitals. Professor Klebs, who has tried his new method of treating cholera in Hamburg, writes to the *Frankfurter Zeitung* as follows: "My method is by no means based on the principle of Koch's tuberculin and is therefore not exposed to the prejudice which might be awakened if it were. All that it has in common with tuberculin is that it has to do with the products of bacteria. My anticholera is a substance isolated from the raw product by chemical means, on the principle on which I obtained tuberculoidin out of tuberculin by the separation and removal of the poisonous ingredients of the cultivations, so as to get the salutary substance pure." An Imperial Commissioner has been appointed for the hygienic control of the Rhine and its affluents. It is credibly stated that the new Hamburg sand-filters, which will cost 7½ million marks (shillings), will be ready next June. The Cholera Commission in the Imperial Office of Health has published its opinion that there is no danger whatever in eating well boiled or roasted fish, crabs and other edible aquatic animals; that sea-fish may be eaten without

scruple, if only salted or smoked, that there is no reason to abstain from butter and soft cheese, unless they have been washed with cholera-infected water or prepared in unclean vessels or with dirty hands, and that goods which are forwarded dry are not fitted to carry cholera contagion. "Timid persons," it adds, "can disinfect the boxes, barrels or the like in which the goods have been received with slaked lime or solution of carbolic acid." The death-rates of the German cities in the week which ended on the 17th ult. were as follows: Elberfeld, 16.6 per 1000; Frankfurt-on-the-Main, 16.9; Barmen, 18.2; Halle, 19.3; Dresden, 19.4; Bremen, 19.9; Nuremberg, 20.6; Berlin, 21; Stuttgart, 21; Strasburg, 21.3; Breslau, 23.4; Krefeld, 24.1; Hanover, 25.2; Dantzic, 26; Munich, 26; Cologne, 26.2; Königsberg, 26.2; Stettin, 27.4; Leipsic, 28.1; Brunswick, 29.4; Aix-la-Chapelle, 29.5; Altona, 30.8; Magdeburg, 31.1; Chemnitz, 33.8; Hamburg and its suburbs, 148.5.

#### *"The Black Death."*

A Berlin paper takes the following description from Russian papers:—"The Asiatic cholera and the plague are nothing compared with the terrible epidemic which has been scourging the population of Turkestan for some days past. A report of the Governor-General of Turkestan, which arrived at St. Petersburg on Sept. 23rd, stated that 'the Black Death,' as the Tartars call the devastating epidemic, visited the district of Askabad, which had a population of 30,000, on Sept. 10th and swept away 1303 victims in six days. Against the Black Death, which has been known in Western Asia for a long time past, there is no remedy. Like a death-bringing poisonous desert wind it suddenly attacks whole regions, sweeps away man and beast, and then vanishes as swiftly as it came. It begins with violent ague fits, which last for about an hour, at intervals of five minutes, shaking the patient from head to foot. Then comes intolerable fever heat, the vessels swell, the pulse beats faster and faster and the temperature keeps constantly rising. The patient is seized with convulsions and fainting fits and tortured with terrible pains. Suddenly the limbs become cold and rigid, the patient cannot move, and only utters from time to time a wailing sound that strikes all who hear it with horror. This second stage lasts only from fifteen to twenty minutes, and then, after a short interval, during which heavy breathing is the only sign of life, death comes. Then large black plague-boils cover the body and decomposition sets in in a few minutes."

Berlin, Oct. 4th.

## Medical News.

UNIVERSITY OF DURHAM.—FACULTY OF MEDICINE.—At the Convocation held on October 1st the following gentlemen were recommended for the degrees specified:—

*Degree of Doctor in Medicine for Practitioners of Fifteen Years' Standing.*—William George Crosswell, L.R.C.S., L.R.C.P. Edin., and Arthur Bayly Vane, L.R.C.P., L.R.C.S. Ed., L.S.A.

*Doctor of Medicine.*—Percy Rutherford Adkins, M.B. Durh.; Robert Crowson Bonington, M.B., B.S. Dur.; Soptimus Bodger, M.B., B.S. Durh.; George William Davis, M.B., B.S. Durh., M.R.C.S., L.R.C.P.; Arthur William Dawson, M.B. Durh., M.R.C.S.; Charles Chester Eardley Willmot, M.B., B.S. Durh.; Arthur Hardwick, M.B. Durh.; Charles Egerton Jennings, M.B., B.S. Durh.; Arthur Waldemar Brougham Ward, M.B., B.S. Durh., M.R.C.S., L.R.C.P.; Thomas Watts, M.B., B.S. Durh., M.R.C.P., L.R.C.P.; Robert James Williams, M.B. Durh., M.R.C.S., L.R.C.P.

*Bachelor in Medicine (Honours).—Second Class:* William Harvey Maddlow, M.R.C.S., L.R.C.P., and Berthold Bezly Thorne Thorne, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Francis Herbert Marson, Mason College, Birmingham; James Powell Willis, College of Medicine, Newcastle-upon-Tyne.

*Pass List.*—Arthur Badcock and William James Nathaniel Vincent, M.R.C.S., L.R.C.P., London Hospital; William Henry Bishop, Henry King Dawson, Reginald Green, John Stratford Hall, Willo Oliver, William Ernest Peacock, Samuel Short Whillis, and George James Williams, College of Medicine, Newcastle-upon-Tyne; Ernest Chittenden Bridges, M.R.C.S., L.R.C.P., and Lancelot William Rolleston, St. Bartholomew's Hospital; Hugh Somerville Burniston and Ronald Angus Dalrymple Daniel, L.R.C.S., L.R.C.P. Edin., L.S.A., St. Mary's Hospital; Edward Eden Cass, Yorkshire College, Leeds; Francis William Clark, M.R.C.S., L.R.C.P., D.P.H., and George Elam, M.R.C.S., L.R.C.P., Middlesex Hospital; Thomas James Selby, L.R.C.P., L.R.C.S. Edin., Edinburgh School of Medicine; Harry Shore, Mason College, Birmingham; Hubert Samuel Stockton, M.R.C.S., L.S.A., Charing-cross Hospital.

*Bachelor in Surgery.*—Arthur Badcock and William James Nathaniel Vincent, M.R.C.S., L.R.C.P., London Hospital; William Henry Bishop, Henry King Dawson, Reginald Green, Willo Oliver, William Ernest Peacock, Samuel Short Whillis, James Powell Willis, and George James Williams, College of Medicine, Newcastle-upon-Tyne; Ernest Chittenden Bridges, M.R.C.S., L.R.C.P., William Harvey Maddlow, M.R.C.S., L.R.C.P., Lancelot William Rolleston, and

Berthold Bezly Thorne Thorne, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Hugh Somerville Burniston, St. Mary's Hospital; Edward Eden Cass, Yorkshire College, Leeds; George Elam, M.R.C.S., L.R.C.P., Middlesex Hospital; Francis Herbert Marson and Harry Shore, Mason College, Birmingham; Hubert Samuel Stockton, M.R.C.S., L.S.A., Charing-cross Hospital.

**ROYAL UNIVERSITY OF IRELAND.**—The following have passed the Third Examination in Medicine of the University:—

*Upper Pass Division.*—Emily E. Eberle, William J. Forbes, Robert J. McKeown, Robert Watt. (All these may present themselves for the further examination for Honours.)

*Pass Division.*—James C. Adams, Joseph T. Ahern, William T. Allen, Charles Bluet, John G. Clokey, William J. Dargan, Mina L. Doble, Walter Farrington, Francis Gallagher, Jane S. Galletly, George W. Griffith, Joseph Lowry, Joseph McGrath, Thomas T. McKendry, Samuel M. Magowan, Douglas C. Moore, William T. Niblock, Martin O'Dea, David A. Porter, John H. Thompson, William D. T. Thompson.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.**—The following have passed the Preliminary Examination:—

J. S. Ashe, J. Beasley, R. Berthon, W. S. Canton, J. M. Conway, A. T. Cresswell, W. C. Croly, L. M. C. Cummins, T. Edwards, \*F. C. Fitzgerald, R. Fisher, R. A. Fuller, J. Glendinning, James Gordon, J. J. Greene, A. C. Ha'choll, T. Jordan, W. Jordan, J. Kean, \*S. G. Longwood, J. J. Lynch, F. J. Moore, E. Moynihan, D. J. O'Meara, M. F. O'Sullivan, R. W. Pearson, L. K. Popham, D. Power, J. J. Prescott, T. A. Rooke, W. M. Rowlett, \*J. S. Sheil, J. A. Whittle.

*Physics.*—\*W. Adrian, J. Clarke, A. O'D. Kelly, F. A. Morris.

\* For a portion of the examination only.

**CHARING-CROSS HOSPITAL MEDICAL SCHOOL.**—The scholarship of 60 guineas, open to students of the Universities of Oxford and Cambridge, has been awarded to Mr. Walter S. Sheppard, of Christ's College, Cambridge. The entrance scholarship of 120 guineas has been awarded to Mr. Sidney Herbert Berry and that of 60 guineas to Mr. Alfred Burn.

**PRESENTATION OF A MEMORIAL BRASS BY DR. R. SAUNDBY.**—A memorial brass bearing the following inscription has just been erected in Saundby Church, Nottinghamshire, in memory of an old inhabitant of the village, from whom, it is stated, the village is named. The inscription runs as follows:—"In loving memory of Robert Saundby, born June 6th, 1810, died January 17th, 1880; and of Emma Sarah, his wife, born November, 1807, died January 28th, 1880. This brass was erected by their only son, Robert Saundby, M.D., F.R.C.P., physician to General Hospital, Birmingham."

**UNIVERSITY COLLEGE, LONDON.**—Her Majesty's Commissioners for the Exhibition of 1881 have placed at the disposal of the Council of the College the nomination to a scholarship of £150 for the year 1893. The scholarship is intended "to enable students who have passed through a college curriculum to continue the prosecution of science with the view of aiding in its advance or in its application to the industries of the country." Out of the late Mr. Berridge's charity legacy the trustees have allotted to University College the sum of £10,000 for the promotion of the study of hygiene. The following gentlemen have been recommended for Medical Entrance Exhibitions:—Mr. C. Bolton, £100; Mr. W. R. Battye, £60; Mr. E. P. Chennells, £40.

**ENTRANCE SCHOLARSHIPS.**—*St. Bartholomew's Hospital:* 1. Open science scholarship of £75 in Chemistry and Physics to Charles Todd, B.A. Cantab., Clare College. 2. Open scholarship in Biology and Physiology of £75 to Walter d'Este Emery, of Mason's and Queen's Colleges, Birmingham. 3. Open science scholarship in Biology, Chemistry and Physics, value £150, to Stanley Bean Atkinson, Prel. Sc. Exam., London. 4. Preliminary scientific exhibition in Biology, Chemistry and Physics, value £50, to Joseph Henry Churchill of City of London School. 5. Jeaffreson exhibition in Classics and Mathematics, value £20, to James Hugh Thursfield, B.A. Oxon., Trinity College.—*St. Thomas's Hospital Medical School:* The first entrance science scholarship—(1) of the value of £150, has been awarded to Mr. A. W. Sikes; (2) of the value of £60, to Mr. C. G. Seligmann.—*Guy's Hospital:* The first entrance scholarship in Arts, value 100 guineas, has been awarded to Arthur William Nourse of Guildford; the second of 50 guineas to Charles J. Thomas of Aberbeeg. The first open scholarship in Science of 125 guineas has been gained by Edmund Ivens Spriggs of Market Harborough; the second of 50 guineas to Frank W. Goldie of Clapham, S.W. Certificates of honour have been awarded to Richard T. Fitz-Hugh of Nottingham, and to Hubert John Starling of Warrington-crescent, W.

**MR. C. BOOTH MELLER** has been awarded a grant for successful public vaccination in the Cowbridge district of the Bridgend Union. He has also obtained a similar grant as public vaccinator for the Bonvilstone district of the Cardiff Union.

**PRESENTATIONS.**—On October 3rd the friends and patients of Dr. Alexander Morison presented him with a beautifully illuminated address and a costly service of silver, on the occasion of his leaving Highbury.—Mr. S. T. D. Weston, L.R.C.P., L.M. Edin., M.R.C.S., of Handsworth, has been presented by the railway *employés* of the ambulance class established in that district, with a handsome silver inkstand, suitably inscribed.

**THE MAYORALTY OF BRIGHTON.**—Last Monday evening a well-attended meeting of the members of the Town Council took place at the Brighton Town Hall to consider as to the selection of a gentleman to fill the office of mayor during the civic year, commencing on Nov. 9th next. The present mayor, Alderman Dr. Ewart, was unanimously invited to retain the office for another year, and in response to the earnest solicitations made to him Dr. Ewart expressed his readiness to accept this invitation. Accordingly the mayor will at the annual meeting in November be nominated once more for the position of Chief Magistrate of Brighton.

**DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.**—The report for the quarter ending Sept. 30th states that the financial position of the hospital continues to be generally satisfactory. The number of patients remaining in the wards at this date was 254. Dr. Robertson in his address, whilst crediting the success of the hospital treatment to the air of Buxton and the dietary arrangements of the institution, said that very much of the relief obtained must attach to the use of the thermal water, which had been resorted to for the relief of the same diseases from time immemorial.

**THE METROPOLITAN ASYLUMS BOARD.**—The number of patients remaining in the several fever hospitals of the Metropolitan Asylums Board at midnight on Oct. 4th was as follows:—Eastern Hospital, 407 scarlet fever, 64 diphtheria and 42 enteric fever; North-Western Hospital, 399 scarlet fever, 95 diphtheria and 21 enteric fever; Western Hospital, 301 scarlet fever, 47 diphtheria, 2 typhus and 15 enteric fever; South-Western Hospital, 299 scarlet fever, 55 diphtheria and 23 enteric fever; South-Eastern Hospital, 400 scarlet fever, 19 diphtheria and 13 enteric fever; Northern Hospital, 864 scarlet fever and 18 diphtheria; Gore farm Hospital, 772 scarlet fever. On the same date on the hospital ship *Atlas* there were 2 cases of small-pox.

**LANCASHIRE AND CHESHIRE SANITARY ASSOCIATION.**—The first meeting of the council of this Association was held on Sept. 30th at Manchester, the Rev. H. S. Patterson presiding. The Association has for its object the improvement of the sanitary condition of the homes and business premises of the members. At the present time, it was stated, not one house in 100 was in a safe sanitary condition, and defective drains were the cause, directly and indirectly, of a vast amount of sickness and discomfort, and an enormous number of preventable deaths annually occurred which could be traced to the same cause. The Association enabled members to have the sanitary arrangements of their houses tested and reported upon by a thoroughly reliable and disinterested expert. The Society was entirely a mutual one. If the receipts during the year exceeded the expenses the members would have the benefit of the surplus.

**MEDICAL DEFENCE UNION (LIMITED).**—At a Council meeting held at the rooms of the British Medical Association on Wednesday, 28th ult. (Mr. Lawson Tait in the chair), the secretaries reported that since the last meeting seventy-four fresh applications for membership had been received and accepted; one application was refused. In the case of a member who was maligned by a co-official of a workhouse the secretaries were instructed to forward to the clerk of the guardians a copy of the letter of the traducer, which "this Council is of opinion is a sufficient vindication of the member's character." To counteract current systematic misrepresentations, the secretaries were instructed to make it more generally known that the London office of the Union was 64, Longridge-road, S.W. It was resolved to report the conduct of a medical man in covering a notorious unqualified practitioner to the General Medical Council and also to his licensing college.

**THE PARIS MUNICIPAL COUNCIL AND ENGLISH SANITATION.**—As a precautionary measure the Paris Municipal Council has voted a grant of £160 to cover the expenses of a journey to England of delegates appointed to study the system of filtration of the water-supply for large cities, to which the Council-General of the Seine has added its support.

Notes, Short Comments & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

We cannot undertake to return MSS. not used.

A CURIOUS INCIDENT.

A CURIOUS case occurred recently in the out-patient department of one of the Metropolitan Hospitals. A woman attending for fibrous stricture of the rectum said she had swallowed a sovereign and a half about a fortnight before, "when larking." The surgeon in attendance examined the rectum and removed three sovereigns from the stricture with a pair of forceps at one grip.

Amicus asks for information on the following points:—1. What is the best way to get information respecting medical practice in the United States of America? 2. What prospects are there for an English qualified medical man with capital at command? 3. What are the fees there for advice and medicine, and visiting fees? 4. What are the medical papers of the States and when published?

Dr. W. L. Reid (Glasgow).—We shall be glad if our correspondent will forward the manuscript.

Dr. Clement Dukes.—The matter has had and is still receiving our serious attention.

Mr. John N. Brown.—We do not know the truss spoken of by our correspondent.

"DAMP DETECTORS."

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me if the instruments sold by opticians under the name "damp detectors," for ascertaining dampness in beds, are of any practical use? I am, Sirs, yours truly, October, 1892. CAUTION.

DOCTORS OF DENTISTRY IN GERMANY.

THE British Journal of Dental Science says:—

"Several American dentists in Germany have been fined by the courts for using the title 'Doctor.' The only titles of 'Doctor' recognised in the Empire are 'Doctor of Medicine,' 'Doctor of Law,' 'Doctor of Theology' and 'Doctor of Philosophy.' It has been held by the courts that anyone practising as dentist and using the title 'Doctor,' although he may possess such a diploma as Doctor of Theology, implies that he is a Doctor of Medicine, thus misleading the public. This will prevent those dentists holding the D.D.S. or D.M.D. diplomas calling themselves 'Doctor.'"

Why not here?

Madras.—We do not think it would be right to publish a letter dealing with the subjects in question unless the writer's name were attached thereto.

Mr. S. F. Hoffnung (Pont-street).—We are much obliged for our correspondent's prompt courtesy.

POISONOUS SYMPTOMS CAUSED BY EUCALYPTUS GLOBULUS.

Dr. Benjafeld writes from Tasmania:—

"I have been called in to cases of apparent poisoning by eucalyptus globulus, but all of them soon recovered. E. G.—, aged two years, climbed up to her mother's store of household medicines, and poured about a teaspoonful of pure oil on some sugar and swallowed it. Within half an hour she began to stagger. Then she became violently sick and lost all power over her legs, so that when attempting to stand she dropped down helpless. A sort of intoxicated torpor then set in. We could awaken her by shaking and calling, but she immediately relapsed. The pulse was quick and strong; the pupils were slightly contracted. This lasted for about three hours, when she woke up perfectly right and ate a good meal. Another child drank an unknown quantity out of a bottle and had the above symptoms very marked, also had great difficulty in breathing; but, by report brought to me from the Bush, where it occurred, she soon recovered. From experience here, where we have never seen Asiatic cholera, I should expect it to be a good germicide and stimulant for this disease. It might safely be given in half-drachm doses, which would quickly saturate the system with the drug; or drachm doses in milk might be injected into the bowel."

Vixen writes to inquire whether he is justified in starting practice on his own account in the village of — in face of the following facts.

1. For three months during the spring of the present year he had charge of a practice in —. This practice was too small to sell and too small to clear the expense incurred in continuing it, so it was closed. 2. During these three months our correspondent acted as locum tenens for a fortnight for Dr. A. and for a week in place of Dr. B. of the same village. 3. He then left —, but returned after an interval of two months, and acted for three weeks as locum tenens for Dr. C. and for a week at the same time for Dr. A. Six weeks have elapsed since he left — the second time. Drs. A., B. and C. object to his coming to start practice amongst them.

Ambulance (Mold).—Our correspondent should make inquiry of the Medical Department of the War Office on the subject. A letter addressed to the Director-General of the Army Medical Department, 18, Victoria-street, S.W., would no doubt procure him the information.

Dr. J. R. W. White.—The communication was received and is being considered.

Dr. W. Whamond.—We see no reason for the further discussion of the question.

WINTER QUARTERS.

To the Editors of THE LANCET.

SIRS,—I and, no doubt, very many of my professional brethren are just now being daily asked by our patients, who have been perhaps for years past accustomed to winter in the south of France, and to whom it has become almost a necessity to avoid the damp cold of an English winter, whether, in view of the epidemic of cholera now so widely spread in Europe, we can safely advise them to do so this year; but we have no means of getting such information as enables us to answer these inquiries. There are no reports in the daily papers, so far, of any cholera in that part of France. But this affords no certainty of what may really be going on there; for the authorities and others in the various *villes d'hiver* are so much concerned in concealing any such outbreaks at the present moment that they will not voluntarily give any information, or even will give false assurances on the subject. You, Sirs, have no doubt exceptional opportunities of learning the truth about this matter, and you would do us a great kindness if you could give in an early number of THE LANCET such information as you may have, or may be able to obtain, as to the freedom or otherwise from cholera of the various winter stations from Marseilles to Mentone inclusive. Of course, at first glance, as a matter of self-interest in retaining our patients here for the winter, we would rather say, "Do not go abroad this year." But even when fully considered this might not in the end be to our own advantage; for we had better retain our chronic invalid patients for the six summer months only, for perhaps years to come, than have them die on our hands this winter in England.

I am, Sirs, yours obediently,

Oct. 4th, 1892.

M.D.

Enquirer would be glad to be informed of any educational establishment where a boy aged eight years, delicate, liable to fits, and microcephalic, could be received for moderate payment. He shows some capability for learning, but is unmanageable at home and quite unfit for ordinary school training.

M.B., M.A. writes:—"The new departure taken by the editors and publishers of 'Kelly's London Medical Directory' in prepaying the reply to their queries is a step in the right direction, and for which they deserve the thanks of the profession."

Crisis.—Reports in the lay press of "cures" for this or that disease, organic or functional, are in general utterly unscientific and appeal only to those who have no knowledge of disease. Our correspondent should discredit the report he refers to.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. E. Armstrong, Newcastle-on-Tyne; Mr. Barber, Bow; Mr. G. Sherman Bigg, London; Dr. J. B. Ball, London; Messrs. Baillière, Tindall and Cox, London; Dr. Broadbent, London; Mr. R. J. Blackham, Rhondda Valley; Mrs. Behnke, London; Dr. Bobardt, Clulow; Dr. Brown-Séguard, Paris; Mr. Birchall, Liverpool; Mr. J. W. Ball, London; Mr. W. M. Banks, Liverpool; Dr. Croke, Beverley; Messrs. Condy and Mitchell, London; Mr. H. Athill Cruttwell; Messrs. Cassell and Co., London; Mr. Brudenell Carter, London; Dr. Edw. The Publisher cannot hold himself responsible for the return of testimonials &c. sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only a ready means of finding any notice, but is in itself an additional advertisement. Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

# DIGESTIVE ENZYMES.

## ZYMIMISED MEAT and MILK SUPPOSITORIES for Rectal Alimentation.

Physiologists are unanimous in condemning GELATINE as a basis for peptone suppositories, for the mixture of gelatine and peptones is one of the best culture-media for BACTERIA, therefore we have prepared these suppositories with pure peptones and COCOA BUTTER; they are easily introduced, completely absorbed, never cause intolerance, and ARE PERFECTLY STERILE.

The zymimised meat suppositories were thoroughly tested clinically by Dr. Barlow in cases after surgical operations, gastric ulcer, or when for any reason it was found desirable to rest the stomach; in every case the suppository was perfectly absorbed, and afforded excellent results. Mr. Bowreman Jessett (THE LANCET, Oct. 24th, 1891), records the successful operation of combined pylorectomy and gastro-entrostomy when the patient was fed with zymimised meat suppositories.

Zymimised Meat and Milk Suppositories are supplied to the Medical Profession in boxes of 1 dozen at 1/10 per box. Retail 2/6.

### ZYMINE (Fairchild).

ZYMINE is rightly considered as one of the greatest advances in modern medicine. It affords a natural and most efficacious means for the treatment of intestinal dyspepsia. It is our only therapeutical resource in many forms of indigestion and in occlusion of the pancreatic duct, &c. It is our only means of pre-digesting all kinds of foods, administering them fresh and palatable, and in such form that they will not prove a burden upon digestion. It is the only agent which does for the digestive organs what they are unable to do for themselves. It has revolutionised infant dietetics, inasmuch as its addition to cows' milk renders that fluid as easily digested as mothers' milk after the lapse of twenty minutes.

Zymine contains no diluent, such as starch or milk sugar, which additions do not in the least assist its digestive action, and are added simply to increase the bulk and profit. Zymine must not be confounded with commercial Pancreatine—the latter is more expensive and less active.

Zymine supplied to the Medical Profession in 1/2 oz. and 1 oz. bottles at 1/8 and 5/- each. Retail 2/- and 6/-.

### ZYMINE "TABLOIDS."

Where the physician desires to carry on or promote the digestive process in the duodenum, there are Zymine and Zymine Compound "Tabloids." No evidence whatever is forthcoming that a pancreatic powder or liquid will exert any action in the intestine, while the coating (comparatively insoluble in the gastric juice) on the Zymine "Tabloids" affords an entirely different prospect. The great activity of Zymine seems to endow it with special usefulness where the intestinal and pancreatic ferment principles are weak or perverted. Of course, it is in no sense claimed that Zymine is curative; it is only claimed that it is decidedly active in digesting foods in alkaline media—e.g., as in the intestinal secretions.

The Zymine "Tabloids" contain 3 gr. each, and the dose is from one to three "Tabloids" an hour or so after meals.

Zymine "Tabloids" supplied to the Medical Profession in bottles of 25 and 100, at 1s. 6d. and 4s. each. Retail 2s. and 6s. each.

### GLYCERINUM PEPTICUM (Fairchild).

This Glycerine extract of the peptic ferment possesses every requisite of a concentrated solution of pepsin. It is highly active, uniform, and stable, devoid of objectionable odour or taste, is freely miscible without precipitation or cloudiness with all proper menstrua or media, is notably free from all the disagreeable qualities and characteristics of peptone solutions. It contains no alcohol or antiseptics other than Glycerine of the purest quality. Twelve minims will be found equivalent in activity to one grain of the best pure pepsin in a dry form that is to be found in

the market. It will be found upon comparative test of much greater strength than any fluid preparation of pepsin known. It mixes freely, without precipitation or cloudiness, with all clear liquids with which pepsin is or should be employed. Pharmacists will appreciate the facility with which the usual fluid preparations of pepsin may, by means of the Glycerinum Pepticum, be quickly and economically prepared, as there is no loss by filtration. It is agreeable to take, and may be mixed with pure water, wine, or with any of the usual vehicles.

Glycerinum Pepticum supplied to the Medical Profession in 4 oz. bottles, at 1s. 10d. each. Retail 2s. 6d.

### PEPSIN (Fairchild).

IN SCALES OR POWDER.

Possesses the highest standard of Activity and Permanency.

Numbers of physicians have been disappointed in the action of commercial pepsins. Dr. CORVISART of Paris first suggested the employment of the gastric digestive enzyme in enfeebled digestion, and doubtless, as originally prepared, pepsin was found to be of much benefit as an aid to digestion. The immense subsequent demand for pepsin led to the adoption of varying processes for the preparation of the drug.

Numbers of these were found faulty; some were evaporated down at a high temperature and thus destroyed; others who succeeded in obtaining a comparatively active pepsin were tempted to employ various diluents—notably, amongst others, starch and milk sugar. The Pepsin prepared by the Fairchild

process possesses ten times the proteolytic power of commercial pepsins when subjected to the Pharmacopœia test—i.e., one grain will digest 1000 grains of coagulated albumen instead of 100 grains only. Those pharmacists anxious to obtain a pepsin of the greatest activity for the preparation of wine, elixir, or solution should order the Fairchild's Pepsin in scales or powder. It is ten times as powerful a digestive agent and is not more expensive than ordinary commercial pepsins.

Dr. BURNEY YEO says: "Pepsin is largely given to promote the activity of the stomach itself. For this purpose many preparations exist, but some are very uncertain, and many probably quite inert."

The EDINBURGH MEDICAL JOURNAL writes: "Pepsin (Fairchild) excels all other preparations of Pepsin with which we are acquainted."

Pepsin, either in scales or powder, may be given spread on bread-and-butter or in the convenient form of sugar-coated "Tabloids"; each "Tabloid" contains one grain of pepsin with the appropriate quantity of acid and aromatics.

Supplied to the Profession in bottles containing 25 and 100 "Tabloids," at 1/2 and 3/6 each. Retail 1/6 and 4/6.

Pepsin in scales or powder supplied to the Profession in 1/2-oz. and 1-oz. bottles, at 1/8 and 5/- each. Retail 2/- and 6/-.

### PEPTONISING POWDERS (Fairchild)

Are packed in corked tubes, each containing the required quantities of zymine and bicarbonate of soda to peptonise a pint of milk or beef-tea. Even the most inexperienced maid can peptonise foods with these powders.

Foods peptonised with zymine are sweet and palatable, are ready for immediate absorption, are soothing and nutritious, and are absolutely indispensable to the proper treatment of gastric and intestinal diseases.

Zymine is frequently proscribed internally in intestinal dyspepsia in the form of "Tabloids." Each "Tabloid" contains 3 grains of zymine; and when taken with meals they promote perfect absorption of the foods and relieve the sense of oppression and malaise usually present in such cases.

Supplied to the Medical Profession in boxes containing 1 dozen Tubes at 1/2 per box. Retail 1/6.

Zymine "Tabloids" and Zymine Comp. "Tabloids," 25 and 100 in bottles, 1/6 and 4/- each. Retail 2/- and 5/-.

# PALATABLE TONIC LAXATIVE.

## FERRIS & CO'S PATENT

# CASCARA

Prepared with the finest sweetened Eating Chocolate, the proportion of the active ingredient being carefully adjusted so that each Tablet or Bonbon contains a dose equivalent to twenty minims of the Fluid Extract of Cascara. The Tablets are of such a form that they can be easily divided, should a smaller dose be desired; and the taste can hardly be distinguished from that of ordinary Chocolate.

"Your tasteless liquid extract of *Cascara Sagrada* and the Bonbons have given me great satisfaction. A little patient greatly appreciates the bonbons.

"—, M.R.C.S.

"To Messrs. FERRIS & Co."

In habitual or chronic constipation. Invaluable for children, ladies, and invalids. No nauseous bitter taste. By far the most agreeable form of administering *Cascara Sagrada* yet introduced.

1s. 9d. Boxes; 18s. per doz.

# CHOCOLATE

"DEAR SIRS,—Please send me a dozen boxes of your Cascara Bonbons. They are a very pleasant way of taking a valuable and nauseous medicine, and they answer their purpose admirably.

"—, L.R.C.P., M.R.C.S.

"Messrs. FERRIS."

# BONBONS.

## GLYCERINE AND CODEIA JELLY (Ferris).

Prepared at the suggestion of Dr. G. S. Mahomed, of Bournemouth, and recommended as a pleasant and serviceable agent in the treatment of chronic laryngitis, phthisical cough, &c.

From the PRACTITIONER:—"FERRIS & Co.'s CODEIA JELLY. This is a pleasant-looking and pleasant-tasting preparation of Codeia with Glycerine, Citric Acid, and Gelatine. We have tried it in a case of phthisis with hacking laryngeal cough, in which other remedies caused nausea. The soothing effect was marked, and the patient was so agreeably surprised, that the jelly was finished almost too quickly. There is much shrewdness in the remark of Dr. Mahomed, of Bournemouth, who says of such preparations that 'patients take them more readily than ordinary medicines, and if unrelieved are less prone to be discouraged.' Many practitioners will welcome this useful compound."

In Glass Jars, 2s. each; 21s. per doz.

At the suggestion of several of our medical friends we have introduced a modification of our well-known GLYCERINE AND CODEIA JELLY in the form of PASTILLES. They are prepared with Codeia, Glycerine, Citric Acid, and Gelatine, and are delicately flavoured. Each pastille contains exactly  $\frac{1}{10}$  grain Codeia, and nearly half its weight of pure Glycerine.

## GLYCERINE AND CODEIA PASTILLES (Ferris).

In Boxes, 2s. each; 21s. dozen.

## SYR. PECTORALIS RUB. (Ferris).

A NEW ELEGANT AND EFFICACIOUS COUGH LINCTUS.

The active ingredients are Morphia, Chloroform, Hydrocyanic Acid, Hydrobromic Acid, and Glycerine, and the preparation is delicately coloured.

Price 1s. 2d. per lb.

"NEWENT, GLOUCE., Dec. 14th, 1890."

"DEAR SIRS,—I should feel obliged by your sending me by return a W. quart of Syr. Pectoralis Rub. I find it of very great value just now, being not only a grateful but efficient cough remedy.

"Yours truly,

"MESSRS. FERRIS & Co."

Clinical Lecture

BASIC PULMONARY CAVITIES, THEIR DIAGNOSIS AND TREATMENT.

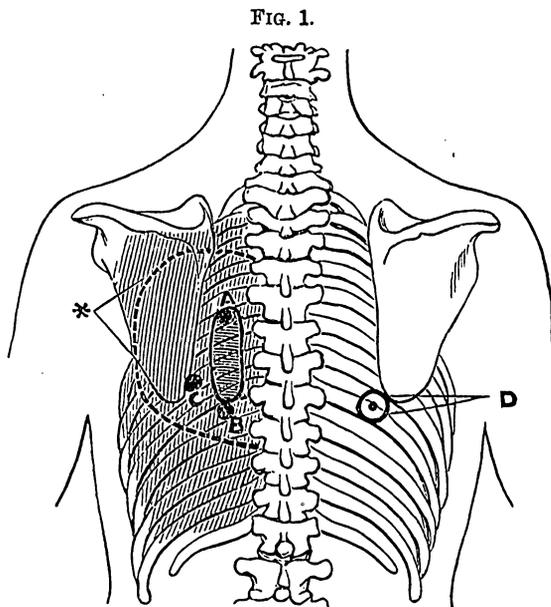

Delivered at the Middlesex Hospital on Feb. 14th, 1890,  
By SIDNEY COUPLAND, M.D., F.R.C.P. LOND.,  
PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—Although in the main the subject of excavation of the lung is of pathological interest, yet it contains also several points for consideration both in diagnosis and treatment, for whilst, perhaps, more than 90 per cent. of such cases are of tubercular origin, the remainder may be caused by various conditions which it is of prime importance to distinguish. In illustration of this I propose to relate the details of a case now in Murray ward in which the question of direct treatment has become matter for grave consideration.

F. B.—, eighteen years of age, was admitted on Dec. 28th, 1889, and at the present time is suffering from a paroxysmal cough at infrequent intervals and mostly accompanied with the expectoration of purulent sputa, airless and of a penetrating foul odour. They are easily brought up in quantities averaging a drachm at a time, after which there is an interval of freedom from cough. The odour of the breath is offensive. The sputa have been several times examined by Dr. Wynter and my house physician, Mr. Norton, and have been found to consist mainly of pus, some threads of elastic tissue being met with on one occasion, but never any tubercle bacilli. This fetid expectoration at once suggests the presence in the chest of a receptacle where the secretions can accumulate and decompose. It does not necessarily imply a pulmonary cavity, for it might occur from a loculated empyema communicating with a bronchus or from more or less general bronchial dilatation, and even some special forms of chronic bronchitis. It is not, however, a characteristic of tubercular excavation, and therefore the failure to find bacilli is not *prima facie* surprising. The patient is a sparely nourished girl; she has even gained flesh since her illness, having had comparatively slight pyrexia; her appetite has been good and the bowels inclined to constipation. It is to be noted that there is some clubbing of the fingers. The chest appears to be fairly symmetrical, but on measurement and by the cyrtometer it is found that the left side is about half an inch less in girth than the right at the lower part, whilst posteriorly the latter seems decidedly fuller. There is less expansible movement of the left side than of the right, until after a fit of coughing, when the movement becomes almost equal on the two sides. There is no inspiratory recession at any part. Vocal fremitus is weak, but equal over the two sides in front, and decidedly better marked over the left posteriorly. There is good resonance on percussion over the right lung, front and back. In the left infra-clavicular region the note is higher pitched than in the corresponding part on the right, but elsewhere in front it is of the same normal character on the two sides. The left back is, however, quite dull, except in the supra-spinous fossa, the dullness being more absolute over the lower than the upper half. On auscultation there is harsh vesicular breathing, with somewhat prolonged expiration over the whole of the right lung; but at a point just internal to the scapular angle the breath sound has a faintly bronchial character, the expiration being blowing. (Fig. 1, D.) Here also there is distinct bronchophony. Over the left lung the auscultatory signs are very different. In front, at the apex and down to the second rib, there is rather distant blowing breathing. Below this the breath sounds are almost inaudible, but the cardiac sounds are very distinct. Behind, over a wide area, extending from the spine of the scapula above and involving the whole of the scapular and inter-scapular regions, reaching outwards to the posterior axillary line at the level of the eighth rib and inwards to the vertebral column at the level of the ninth dorsal spine, there is bronchial breathing, which attains great intensity in the vertebral groove over the angle of the eighth rib below (Fig. 1, B), and also opposite to the fifth spine above (Fig. 1, A). A

third point of marked intensity is just below the angle of the scapula (C). In these sites, but especially the first named, it may be described as amphoric. Sometimes it is very feeble, but after a paroxysm of cough the sound is heard in full intensity. Then, too, some fine clicking râles are produced, and these are also to be heard on deep inspiration over the greater part of the area. Extremely well marked bronchophony and whispering pectoriloquy can be heard, especially in the vertebral groove between the two points named (A and B). The heart's apex beat is in the fifth interspace, just within the nipple line; the sounds are clear and well pronounced. The abdomen is natural and the urine normal.

Such being the clinical signs yielded by this case, there is hardly any escape from the conclusion that there is some excavation in the upper part of the left lower lobe. Although there is also blowing breathing at two other points—namely at the left anterior apex and the right scapular angle—there is not such a degree of certainty in the diagnosis of a cavity at these places. It must be admitted that the signs met with over a cavity are not distinctive; and, further, that cavities may exist in the lung beyond detection by physical examination, if they are deeply seated or not in communication with a bronchus. We may, however, have (a) flattening of chest wall, with

The area over which bronchial breathing was audible is indicated by dotted line (\*). A B C are points at which mostly intense amphoric quality of breathing was heard; whilst between A and B pectoriloquy was very well marked. At D faint blowing breathing audible.

impaired expansion; (b) dullness on percussion; (c) bronchial breathing; (d) bronchophony and pectoriloquy. These are the ordinary signs, and it will be at once obvious that they are not to be distinguished from those due to consolidated or compressed lung. If they alone were present it would be hazardous to diagnose the presence of a cavity. Nor does the absence of one or other of them disprove its existence. Thus the degree of (a) depends largely upon the site and size of the excavation and its nature. If the cavity be surrounded by a fair amount of alveolar tissue this sign may not be marked; it is usually best seen over the apical cavities of phthisis. For a like reason (b) may be obscured; or, on the other hand, when the cavity is of large size, thin-walled and superficial, the percussion note may be almost tympanitic, and the "bell sound" may be elicited or percussion may yield the "cracked-pot" sound. The occurrence of (c) and (d) implies free communication with a bronchus. They may be wholly absent if the cavity be small; but if of fair size the bronchial breathing has a more hollow character, from the production of by-notes, being either cavernous or amphoric, according as the walls of the sac are more or less irregular, or smooth and firm. Moreover, the amount of the contents modifies the sounds produced, and it may happen that they are temporarily suppressed until such contents are evacu-

ated. The quality of the râles present and their production on natural or forced breathing, and on coughing, vary in every degree in accordance with the amount and consistency of the fluid, as well as with the size of the cavity and its freedom of communication with the air passage. Even more reliable as signs of excavation, when the latter condition obtains, are (*d*) bronchophony and especially whispering pectoriloquy, which were so marked in this case. These signs, when heard over a limited area and with such clearness, afford strong presumption of the presence of a cavity. But they are not pathognomonic signs, for they may be well heard over a consolidated lung, and in certain cases over a pleural effusion. As regards the present case it is possible, from the fact that the bronchial breathing is of greater intensity at two or three different points of the area over which it is audible, that more than one cavity exists. It may, I think, be inferred, however, that one at least of them is as large as a Tangerine orange, if not larger. Still it is most difficult to be certain of the size of a cavity. This is by no means continuous with the area over which the blowing breath sound is audible. The area of marked pectoriloquy is a safer guide; but then it must be remembered that the surrounding tissue is mostly condensed, tough and solid, and therefore capable of conducting the voice sounds for some distance beyond the limits of the cavity. One noteworthy feature in this case is the scantiness of râle. Having thus arrived at the conclusion that the source of the fetid expectoration is a cavity or cavities in the lower lobe of the left lung, the next questions to determine are, What is the nature of the cavity? for how long has it existed? what is its probable issue? As guides to the answers one may glance back at the previous clinical history of the patient.

When admitted into the hospital on December 28th all that could be elicited was that both her parents had died from "consumption," but that she had two brothers and two sisters in good health and had lost none. She had been ill for a week, having taken cold, followed by a cough, difficulty of breathing and pain in the region of the left shoulder blade. Further inquiry elicited that she had never been laid up before, but that she "had had a cough for as long as she could remember"; that until two years ago the cough was dry, but from that time there had been fetor of the breath and expectoration, which had always similar characters to those existing at the present time. She was unable to assign any reason for the change in the character of the cough; had never had blood spitting or night sweats; had always enjoyed a good appetite and was never incapacitated from her duties. Even when on taking cold the previous week her cough increased and the fetid expectoration became more profuse she remained up until within two days of her admission, when the pain in the shoulder compelled her to keep to bed. In spite of the indefiniteness of the statements bearing on the origin of the fetid expectoration it is clear that this cannot be attributed to any recent change in the lung, such as pneumonic gangrene. Her week's illness was not of the severity of pneumonia, and was apparently nothing more than the lighting up afresh of some permanent mischief in the lung, and this may have been initiated two years previously. I am free to confess that at first, in face of her positive assertion that she had only been ill for a week, my impression was in favour of an acute process—e.g., a gangrenous abscess; but the result of further questioning and the course taken since her admission have shown that that view is quite untenable. The physical signs on admission were much as they are at present. The main differences consist in the fact that at first there was slight general catarrh and the area of tubular breathing on the left side was more restricted than now. It may be noted that with the progress of the case not only did this area appear to extend its limits, but the points at which the breath sound had mostly an amphoric type also seemed to shift. This may be explained by the occasional plugging of a bronchus, whilst it goes far to confirm the surmise that we are dealing with more than one cavity. In addition to bronchitis there was also at first a slight attack of dry pleurisy on the right side. The sputa throughout have had the same characters. There has been only moderate, but notably irregular, pyrexia, the average range being between 98° 8' and 101° 5', but frequently remitting rapidly. It is not true hectic, as in phthisis that is advancing, and is most likely due to the alternating retention and evacuation of pus contained in a cavity. The absence of apical signs is noteworthy, although the examination seemed to point to slight consolidation at the left apex. Still there are no signs of advancing tuberculosis. We have

had the case under observation for six weeks, and during this period there has been no appreciable change in the extent of the local lesion—no manifest constitutional decline. All this is very unlike tuberculous phthisis, in spite of the great probability of inherited taint. Moreover, the repeated failure to find bacilli in the sputum is further evidence against that disease; and, lastly, the situation of the lesion is against it. For if there is one rule in the history of phthisis better established than another it is the early implication of the apex of the lung or its vicinity. As the disease progresses the next part to be invaded, as has been so fully demonstrated by Drs. Ewart and Kingston Fowler, is the upper part of the lower lobe, the "posterior apex" as it is termed. Moreover, primary basic phthisis is a rare event. So that if there be cavity signs in this neighbourhood without any notable implication of the anterior apex of one or other lung, the chances are that the case is not tuberculous phthisis. It is, however, quite possible that the scanty signs at the apex of the left lung in this case are due to an old phthisical lesion. But whether the patient was originally tuberculous or not, we can safely affirm that she is not the subject of advancing tuberculosis at present; and we must seek for another explanation of the presence of the signs of excavation in the left lower lobe.

The only other pulmonary condition which is chronic in its course, so that it alone need be considered in determining the nature of the cavity or cavities, is bronchiectasis. This condition is more frequently met with in the lower lobe of the lung when it is localised and limited. It may be induced by several different kinds of change, of which the chief are: (1) collapse following on pleurisy, (2) pressure on a bronchus, with consequent retention of its secretions, and (3) a foreign body impacted in a bronchus. It may also be associated with chronic pneumonia and with phthisis, whilst not a few cases are really dependent upon congenital atelectasis. Whatever the cause in this case—and we must admit that the history is very deficient on this point—the signs presented are strongly in favour of bronchiectasis; more especially as we may reasonably infer from them that the cavities are multiple. For (*a*) the course has been chronic, (*b*) the sputa and breath fetid, (*c*) the cough paroxysmal, (*d*) the cavity signs are limited to part of one lobe, (*e*) there is an absence of diffuse râle, (*f*) the signs are unilateral, (*g*) the bronchial type of breathing, pectoriloquy and bronchophony, point to a free communication with a bronchus, and (*h*) the amphoric quality of the breath sound points to a certain rigidity of the cavity walls. Hence we conclude that for at least two years there has been limited bronchial dilatation and that, as so often happens, a fresh attack of bronchitis has caused increased secretion, followed by a constant formation of pus, which accumulates and grows fetid in the dilated tubes.

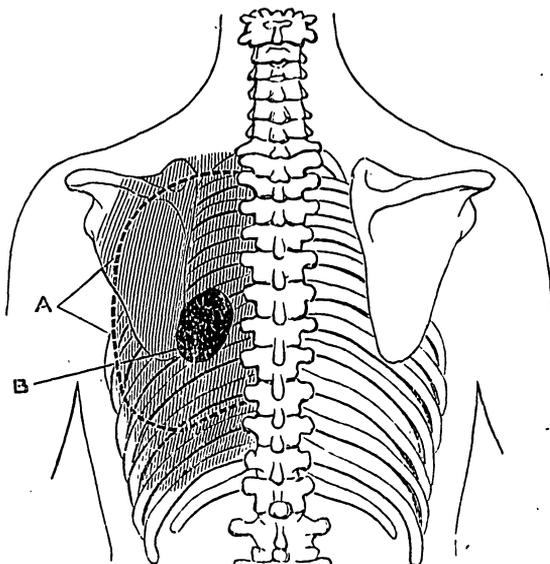

If this be the correct diagnosis, and the alternative of a localized empyema with bronchial fistula is not borne out by the physical examination, then we may inquire what is likely to be the future course of the case and what can be done in the way of relief or cure. As regards the first point, there are certain alternatives:—1. It is conceivable that under the influence of antiseptic inhalations, to correct the fetor and arrest putrefaction, a generous diet and tonic remedies, the local disturbance may abate, the cavity shrink, and for a time at least give no more trouble. 2. On the other hand, a patient with a basic cavity containing foul gas is in danger of incurring septic broncho-pneumonia, from inhalation into other parts of the same lung or even into the opposite lung, of some of the putrefying material. This is a very real and constant danger, and not uncommonly leads to gangrene of the lung. 3. Or the local mischief may extend by ulceration of the walls of the cavity and thus also lead to gangrene. It was on these grounds that last week I consulted Dr. Cayley with reference to the question of surgical interference for the drainage of the cavity. It was agreed to still further watch the progress of the case, in the hope that more favourable spontaneous relief would occur. As days go by, although there is as yet no material deterioration of the general health, but a continuance of the purulent expectoration with the above-mentioned risks thereby entailed, the need for drainage seems to become more imperative. Still we may ask what are the prospects of permanent good resulting from such a measure? Drainage would give vent to the foul discharge, and thus not only obviate the risks of secondary inflammation but facilitate the contraction of the cavity. Such a contraction would be slow and difficult without a drain in some dependent part of the sac. As regards the hope of permanent good by drainage, much depends on whether the cavity be single or multiple.

It is unfortunate in this regard that bronchiectases are mostly multiple. As Mr. Godlee says,<sup>1</sup> "Bronchiectatic cavities, when single (a very rare condition), will be cured by operation; when multiple (a very common condition), they offer but small chance of relief by our present surgical methods. Still, for the reasons stated, an attempt may be made to open the main one, if such can be found, but only if the pleura has been ascertained to be adherent." I think that in this case we should have no difficulty in pointing to the main site of the cavity, which may possibly be single; and if we are correct as regards the chronicity of the process, the probability is that the pleura is adherent, so superficial does the cavity appear to be. As regards the alternative measure of injections into the cavity, that could only be palliative, and in such a case not likely to be of much advantage.

In conclusion, and by way of contrast, I may briefly refer to another patient at present in the same ward who also has a basic cavity in the left lung. In her case the right lung is wholly unaffected, and, beyond some degree of anæmia, she is enjoying fair health, is well nourished, has no fever and has a good appetite:—E. G.—, twenty-three years of age, a maid-servant, was admitted into Murray ward on Feb. 5th, 1890. She has not been strong for the past three years, when she contracted a cold whilst attending a hospital for "housemaid's knee." Since then she has not been free from cough, and at that time she attended two special hospitals in turn. She was admitted into one and was told that she had pleurisy on the left side, for which iodine was applied, but paracentesis was not performed. More recently she has been an out-patient here. Her anæmia dates from the first onset of chest symptoms, and for the past three months she has been suffering from shortness of breath and at times feelings of faintness and palpitation. She has not lost flesh or had any hæmoptysis or night sweats, but for a short time previously to her admission she had diarrhoea, and for a fortnight had been weaker. The girl had been brought up at an orphanage, her father dying at the age of forty-three from asthma, and her mother about the same age from phthisis. No other members of the family are phthisical; there are three brothers and two sisters, some of whom are rheumatic. On admission both feet were slightly œdematous and in the left calf there was a thrombosed vein, with some pain, which soon subsided under the application of belladonna; the chest is symmetrical, and movements above are equal, but at the base the right expands better than the left. On percussion there is dullness over the greater part of the left front and over the whole of the lung posteriorly (Fig. 2); there is good resonance over the right lung before and behind. On auscultation bronchial breathing can be heard in the left infra-clavicular region but it seems rather distant; there are no râles, but vocal resonance is increased and whispering pectoriloquy distinct but slight; behind there is loud, tubular, almost amphoric breathing over the left lung from the apex to the ninth rib (Fig. 2A), where the breath sound becomes very weak; there are intense bronchophony and pectoriloquy above (B), but at the base both vocal resonance and fremitus are absent. The heart sounds are loudly conducted over the whole lung anteriorly and posteriorly. The breathing over the right lung is vesicular and very harsh. The heart's impulse is visible in the third interspace, and the apex beat appears to be in the fifth space nipple line; the first sound at the apex is rough, the second clear, and both sounds are very marked at the pulmonary cartilage, but faint at the aortic cartilage. The expectoration is scanty, purulent and no bacilli can be found in it. The temperature is normal. During the short time the patient has been in the hospital there has been very little change in her condition. Occasionally a few fine crackling râles can be heard over the left lung, both at the anterior and posterior apex and the pectoriloquy in front has become plainer. This case seems to fall into the category of so-called "fibroid phthisis," which has ensued upon pleurisy. We have no evidence that it is tubercular; indeed, its unilateral character is opposed to that as well as its quiescent course; but still one cannot exclude the possibility that the pleurisy, which was probably accompanied with considerable effusion, was of tubercular nature. The disorganisation of the lung, however, is the result of fibroid interstitial pneumonia with secondary bronchiectasis. Here there is no fetor of the secretion, and indeed very little cough or expectoration, so that, apart from the extent of lung involved, which would

itself be a bar to thorough drainage, there is no indication for such interference. So far the treatment in this case, as in the other, has been chiefly by turpentine inhalations and stimulant expectorants.

FIG. 2.

Blowing breathing audible over the whole of the area indicated by A. Well-marked pectoriloquy in region B.

## POSTSCRIPT.

*Sequel to the case of F. B.*—The termination of this case came unexpectedly and in a regrettable manner. It is right, however, to record it as it brings home forcibly the dangers attending the administration of anaesthetics in operations upon the thorax. As the fetid expectoration continued, and even grew worse with commencing indications of its telling on the patient's general condition, it was decided to explore the lung with a view to perform drainage. This was done on March 10th, about four weeks after the above lecture was given. Chloroform was carefully administered, but from the first the patient took it badly, vomiting and coughing much, ejecting a quantity of very foul sputa. My colleague, Mr. Pearce Gould, passed a trocar into the lung over a spot where the amphoric breathing had been most intense, one puncture being made above and another below the eighth rib in the back. No pus escaped, and as some hæmoptysis and cough followed the last puncture and the patient was becoming cyanosed any further attempt was abandoned. She had much nausea and vomiting for some time after the operation. The next day coarse bubbling râles were to be heard over the dull area, whilst the breath sounds were less markedly amphoric. On the 17th a diffuse inflammatory swelling appeared at the site of puncture, with an increase of fever, and as it soon became evident that an abscess was forming here, probably from leakage of pus from the lung, and another operation was decided upon. This was undertaken on the 18th. Chloroform was again the anaesthetic used, and the patient took it better than on the last occasion. It was, however, necessary to place her on the sound side to enable the surgeon to operate. The abscess was evacuated and a cavity in the lung having been found by the use of a grooved needle, a portion of rib was excised, and the cavity was about to be laid open when the patient became suddenly livid and sweated profusely. The operation was discontinued, and she was at once placed on her back, the tongue drawn forward and mucus removed from the mouth. The breathing became stertorous and infrequent, the pulse very feeble and the pupils dilated slowly. In spite of active restorative measures, subcutaneous injections of ether, artificial respiration &c., she never rallied, and died about twenty minutes after the operation had been suspended. At the post-mortem examination by Dr. Sidney Martin it was found that about one inch of the ninth rib had been excised and that the opening led into a dilated bronchus, one of several saccular bronchiectases which occupied a great part of the left lower lobe. The bronchi in the upper lobe were also dilated. The

<sup>1</sup> THE LANCET, April 9th, 1887

lung tissue between the bronchi was consolidated in patches, some of which were of recent date (probably from the disturbance excited at the first operation). The bronchi of the right lung were slightly dilated, and on each side, but especially on the left, the tubes contained blood mingled with muco-pus. The kidneys and liver were the seat of cloudy swelling. It is an instructive fact that physical signs of such intensity should have been yielded by a congeries of dilated sacculæ, of irregular shape, the largest of which did not exceed a bean in size.

ABSTRACT OF A

Lecture

ON

MELANOTIC CANCEROUS DISEASE.<sup>1</sup>

Delivered at the Cancer Hospital, Feb. 5th, 1892,

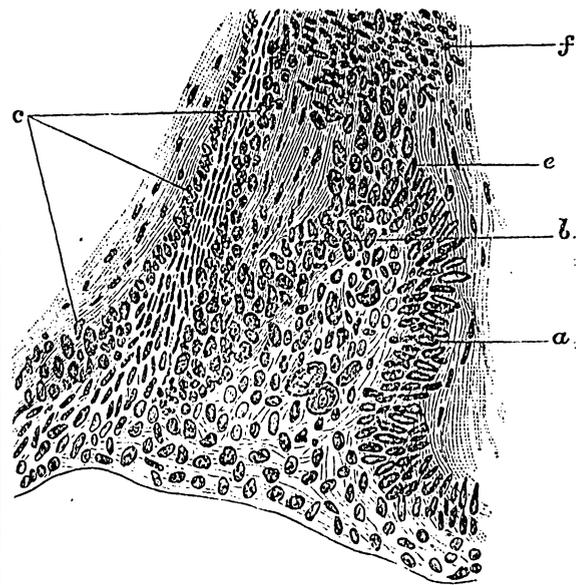

By HERBERT SNOW, M.D. LOND. &c.,  
SURGEON TO THE HOSPITAL;

MELANOTIC CANCER is characterised by the presence of a peculiar pigment termed "melanine," soluble in alkaline solutions, from which it is again precipitated by acids. It is a product of degenerate protoplasm, bears no relation to hæmatine, and so does not influence the composition of the urine. All cancerous disease is due to the proliferation of cells, and the pathological identity of any particular neoplasm is established by the resemblance of the new cells in form or mode of distribution, or in both, to the old, exactly as in the relationship of parent and offspring. Acting upon that principle, which holds good with all varieties of cancer except colloid, we are enabled to refer melanotic cancer to cells which usually secrete pigment. With two or three insignificant exceptions this species occurs in the human body in two localities only, which therefore are the sole tissue sites from which the disease in question originates or can originate. These are (a) the eyeball and (b) the skin. In the eye pigment is normally present for the most part in connective-tissue corpuscles—those of the sclerotic, iris and ciliary processes. The endothelioid cells of the iris and tapetum are also pigmented, as is the conjunctival epithelium of dark-complexioned persons. None of these latter, however, are known to originate malignant disease of any kind. Melanotic cancer of the eyeball therefore must be referred to the connective-tissue structures of that organ and is a true sarcoma. It generally springs from some part of the choroid coat, appearing as a tumour which pushes before it the retina and grows inwards. It is from the beginning extremely painful, that feature being due to the tension which the presence of the superincumbent sclerotic involves. Microscopically it consists of spindle cells arranged in bands as in the ordinary spindle sarcoma, but the new cells with their nuclei are seen to be more or less converted into the characteristic pigment. The disease tends to run an acute course and to generate numerous and widely spread metastases. Like other true sarcomata, however, it shows great reluctance to attack the lymph glands. These organs do not become secondarily infected (as in carcinoma and epithelioma) by the lymph current, but only under circumstances which indicate either a general blood infection on the one hand, or direct infiltration by contiguity on the other. With melanotic cancer of the skin, however, the case is totally different. Pigment here is normally present only in the cells of the rete Malpighii, an epithelial structure; with the exception of a casual migratory cell we find none in the corium. *A priori*, therefore, it is reasonable to infer that melanotic cancer of the integument does not arise from connective tissue, but from epithelium. On further examination this view is corroborated, not only by the microscopic appearances, but also by the clinical career of the disease. The following description is based upon an examination

of forty-three thin sections taken from twenty different cases. Among these I have not met with a single primary melanotic tumour composed of fusiform cells on the integument, although such are occasionally figured in text-books and are common in the eyeball. The ordinary starting point is a pigmented wart; the close resemblance between the warts which give birth to melanotic cancer and those which precede squamous epithelioma was long since pointed out by Sir James Paget. A non-prominent mole or outaneous stain may be antecedent to melanotic developments, as in one of the cases cited. But more commonly there is a warty prominence, such being prone to mechanical injury. The microscopic examination of a pigmented wart, which must always be regarded as a potential melanotic cancer, will aid us in comprehending the formation of the latter neoplasm. Pigmented warts [thin sections of two exhibited] are in the main epithelial structures. There is a central slender stalk of connective tissues continuous with the corium; this is coated with epidermis which sends inwards numberless columns and prolongations inosculating with one another. Pigment is plentiful in the Malpighian rete and occurs almost alone in the deepest layer of that rete—the columnar cells. The central connective tissue core is entirely devoid thereof. This is the pre-cancerous stage. It would seem necessary that the pigment should be abnormally excessive; melanotic disease very seldom begins on the healthy skin even of dark persons, or in parts such as the areola of the nipples, which naturally abound in that material.

In the next we find abnormal proliferation of these columnar cells. Those *in situ* have increased in number; many have apparently severed their original connexion with the epidermis, constituting little isolated clumps within the underlying corium. Other cell clusters, rounded in shape, are still joined to the rete by a narrow peduncle, the result being the peculiar racemose condition of each inter-papillary process shown in the slide exhibited, taken from the vicinity of a melanotic cancer on the pubes. The most recently formed cell collections are brightly stained (by logwood), and but slightly pigmented. (Fig. 1.)

FIG. 1.

From vicinity of melanotic epithelioid cancer, showing two interpapillary processes, with the cells of the Malpighian rete becoming malignant and invading the corium.  $\times 240$ .

In the second cancerous stage we find the epidermis still unbroken, but very thin, and wholly denuded of its columnar rete cells. These are seen diffusely infiltrating the corium and subcutaneous tissue, and are everywhere more or less pigmented. They are surrounded by very numerous leucocytes, the invariable accompaniments of a cancer development in any shape. (Fig. 2.)

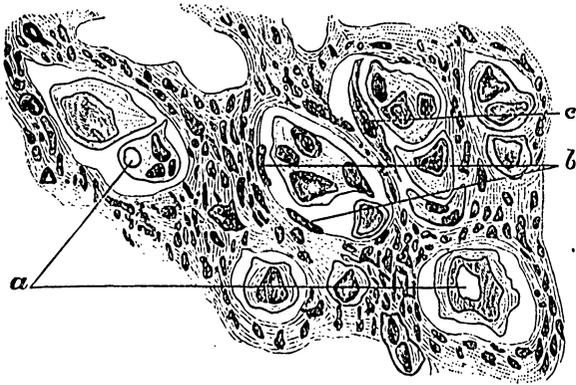

In the third stage the type is that ordinarily described as indicative of alveolar sarcoma. Within each small mesh of the fibrous stroma are found one or several large cells, identical in appearance with those of an actively growing carci-

<sup>1</sup> The substance of this paper also formed part of Cancer Researches, communicated to the Pathological Section at the Nottingham meeting of the British Medical Association.

noma. They betray no indications of connective-tissue origin, are in shape irregularly rounded, with relatively large, excentric, multiple nuclei, which become more numerous the higher the power of the microscope. Huge multi-nucleated corpuscles are common, as in acute carcinoma. Spindle cells are conspicuously absent. Many of the nuclei are vacuolated—a feature pointing to epithelial origin. Some are brightly stained by logwood; others are brownish, black and granular. The neighbouring tissues are full of brown granules and clusters of granules, obviously the product of broken-down cells. This alveolar condition is best seen in sections of a secondarily implicated lymph gland; it is the prevailing type of a melanotic cancer on the integument, though in advanced cases the microscope will display a brown or black mass of debris, with the growing cells only at its margins.

It has become of late years customary to term all melanotic cancers, with rare exceptions, sarcomata. The presence of pigment normally in the Malpighian rete, combined with its absence from the corium, seems to me entirely to negative such an opinion, which is also disproved by the absence of spindle cells. I therefore refer these growths to the columnar cells of the rete Malpighii. The virulence of the cancer proliferation seems to me sufficient to account for differences in microscopic structure between a melanotic cancer of

FIG. 2.

the skin and a common squamous epithelioma. You will note in the former the absence of globes épidermiques and the packing of the melanotic cells in small loculi. Hansemann, in *Virchow's Festschrift*, has lately pointed out that in health cell division by karyokinesis is limited to the two deepest layers of the rete. This view of melanotic skin cancer as an epithelial product is further corroborated by the early period at which the neoplasm secondarily implicates the nearest lymph glands by means of the lymph channels. In addition to their superficial resemblance melanotic sarcoma of the eyeball and melanotic epithelial cancer of the skin are both acute diseases attended by widespread metastases. Hence they have always been confounded. Both, however, are most prevalent in the cancer age—i. e., from thirty-eight to sixty. The former, however, may attack very young children; the age of two years is the earliest I have found on record. Infants are specially prone to malignant tumours of the eyeball—generally, however, gliomata. This exception to the ordinary age rule, which holds good in all varieties of cancerous disease, I attribute to the presence of vestigial remnants of unobliterated foetal structures. Both forms may insidiously attack the bones. The phenomenon is analogous to that insidious infection of the marrow by the cells of mammary carcinoma which I have lately pointed out.<sup>2</sup> Mr. Oliver Pemberton<sup>3</sup> records such latent deposits in ribs, clavicle, sternum, cranial bones and femur. In one or two of his cases the bones were “completely black, but in no other way altered from their natural state.”

A rare and interesting symptom is diffuse pigmentation of the integument. The subcutaneous tissue is a peculiarly

favourable nidus for the propagation of cancer particles of all species. Thus a man with melanotic disease of the orbit, who was lately in the Cancer Hospital under the care of my colleague, Mr. Jessett, displayed between fifty and sixty melanotic growths dotted about the trunk. But sometimes there is little or no tumour formation, and a tract of skin becomes merely puffy, slightly thickened and pigmented. This occurred on the pubes of a woman lately under my care, and Dr. Phineas Abraham figured a case in which almost the whole face and neck had become thus disfigured. The secondary lymph gland or visceral deposits may be as profusely pigmented as the primary lesion or only partially stained, or may be composed of the malignant cells wholly free from melanine. In such cases the comparative recency of the deposits may be stimulated by the amount of pigmentation. As in secondary metastases, the degree of colouration is thus seen to vary, so that there is some reason to believe that in the primary the amount of pigment may be so small as to be inappreciable to the naked eye, and as to be easily dislodged during the process of preparation for the microscope. We may thus have a cancer derived from the columnar cells of the Malpighian rete, but colourless: melanotic cancer without the melanosis. A case apparently of this character was described before the Hunterian Society in December last by Dr. Wightwick. For evidence to the same effect see also Paget's *Surgical Pathology*, article “Melanoid Cancer.”

In spurious melanosis the tumour is stained, often very deeply, by extravasated blood. Although such may seem black to the naked eye, no pigment in granules or clusters of granules is found under the microscope. The cells and their nuclei are stained as usual by the ordinary protoplasm dyes; but we have in addition the remains of abundant red blood corpuscles in the adjoining tissue. The hæmamine may be so abundant as to darken the urine. Of this character were the melanotic cancers described by former writers in such impossible sites as the stomach, uterus, rectum &c., where no pigment is normally present. Old horses, ponies and sometimes dogs are prone to black fibrous tumours, which are said to be non-malignant; the assertion needs verification, and it is uncertain to what class these actually belong. In the human subject an appreciable amount of cancerous pigment in a new growth is assuredly indicative of cancerous disease belonging to one or other of the two varieties here described.

Towards the prompt and early diagnosis of melanotic cancer developments the most important element to be borne in mind is the age of the patient. The severe pain attendant upon sarcomata of the eye generally ensures their speedy recognition by the ophthalmic surgeon. On the other hand, the apparent triviality of the pigmented papilloma which precedes melanotic growths on the skin commonly fails to excite suspicion of danger until there is extensive implication of the lymph glands and it is too late to effectually extirpate the affected area. A pigmented wart which begins to increase in size, the individual being of advanced middle age, is assuredly becoming a melanotic cancer. Any abnormal and prominent collection of pigment on the skin becomes dangerous in later life, and prophylaxis is always preferable to cure.

In respect of surgical treatment, two cardinal phenomena in the clinical course of cases wherein the skin is the primary site call for emphatic notice and indicate corresponding principles of action. These are—(a) the usually insignificant dimensions of the primary lesion; (b) its tendency to rapidly infect the nearest lymph glands. The skin tumour is in the majority of cases very small and, if not tampered with, commonly remains so to the end. Although unsightly and painful, it has *per se* little appreciable effect on the duration of life. The danger lies in the diffusion of malignant cell particles from this primary focus; these always implicate the nearest lymph glands, which intercept them for a time. Eventually they pass beyond such “traps” into the blood current; then death, with multiple visceral metastases, ensues. Palpable enlargement of these glands is unfortunately but a late symptom of deposit therein; by the time it occurs there is almost always implication of deeper organs or tissues. We thus see the utter futility of operative measures which are addressed to the primary lesion only, as also the harm of irritating any growing wart by such pernicious procedures as the application of the ligature or of silver nitrate. We further see the paramount importance of securing, whenever possible, the perfect eradication of those lymph glands which will necessarily be first infected; before enlargement takes place radical removal of such organs in the

<sup>3</sup> Observations on Cancer, 1858, part 1.

axilla, groin, surface regions of the neck &c., before they have undergone appreciable increase in bulk, is a safe and easy measure, which, under the conditions indicated, should never be neglected.

[In exemplification of the principal points involved in the above remarks the notes of four cases were cited at length and the corresponding specimens shown.]

CASE 1.—A gardener, aged twenty-eight, had several congenital moles on the left forearm, one being large and prominent. The top of this was knocked off, and in order to heal the sore first spirits of salt, then chloride of sodium were applied. Excision of the resulting tumour, after a year at a general hospital, left a scar an inch and a half long and half an inch wide, which remained healthy until the patient's death. Two years after the operation an axillary tumour was removed at the Cancer Hospital; it was as large as a turkey's egg, was deeply pigmented in the middle, while each end of the ovoid mass was perfectly free from colour. Death took place one year subsequently, when large masses of rounded growth, devoid of pigment, covered the whole peritoneum.

CASE 2.—A charwoman, aged fifty-three, was admitted into the Cancer Hospital with a large axillary tumour secondary to a melanotic growth on the left middle finger, which had been previously removed at a general hospital. There were ascites and very numerous visceral metastases. After death the axillary mass was found highly pigmented; numerous pulmonary and pleural nodules less so; large deposits in the liver, peritoneum and omentum. On the left middle finger was a very small, white, healthy scar.

CASE 3.—A woman, aged fifty, accidentally wounded the skin about the left great toenail; the sore never healed. Several operations, including scraping of the ulcer and evulsion of the nail, had been performed at a general hospital and by the private medical attendant. When received into the Cancer Hospital there was a small fungating tumour an inch in diameter on the left great toe and a huge mass of lymph glands, some black and ulcerated, in the corresponding groin. Near the latter were numerous subcutaneous nodules, some pigmented, others whitish. The necropsy showed abundant visceral deposits only partially pigmented.

CASE 4.—A married woman, aged thirty-five, had a congenital melanotic wart on the pubes. This was irritated by the lochial discharge and neglect to change the diapers. The wart began to grow, was ligatured by the medical attendant, then became very painful and grew still more rapidly. When first seen the patient was three months advanced in a fresh pregnancy and had extensive deposit in the glands of the groins. Eventually diffuse pigmentation of the whole mons veneris took place, the skin becoming puffy and of a bluish-black colour. Under the stimulus of pregnancy death very speedily ensued, with metastases in the inguinal glands on both sides, both lungs, both pleurae, the liver and the mucous membrane of the stomach.

## REMOVAL OF LEAD FROM THE EAR BY THE USE OF METALLIC MERCURY.

By JAMES P. RYAN, L.K.Q.C.P.I.,  
SURGEON TO THE VICTORIAN EYE AND EAR HOSPITAL,  
AND

JAMES W. BARRETT, M.D., M.S., F.R.C.S. ENG.,  
ASSISTANT SURGEON TO THE VICTORIAN EYE AND EAR HOSPITAL.

IN THE LANCET of April 30th, 1892, there appeared an article by Mr. A. Marmaduke Sheild entitled "Notes of a Case where a Mass of Lead was impacted in the Tympanic Cavity and removed by the Aid of Metallic Mercury." A man of seventy was carrying a pot of melted lead down the ladder of a ship when the vessel gave a lurch, the metal splashed over the side of his head and some of it ran down his right ear. Six weeks later when the superficial burns had healed he came under the treatment of Mr. Sheild. There were then abundant offensive discharge from the ear, total deafness on the right side and oæna. The lead is described as having filled the tympanum, the surface being just flush with the remains of the membrane. Examination with the probe and elevator showed the mass to be firmly

impacted. Shortly after Mr. Sheild made prolonged and cautious attempts to extract the lead or to shift its position, introducing a sharp and small but powerful hook between the floor of the tympanum and the lead. This being turned round took a good hold of the metal. He then exercised an amount of traction which only the gravity of the case could justify. He was able to take a firm hold in like manner of other irregular parts of the mass, but all attempts utterly failed to shift it in the least, and only impressed his mind still more with the firmness of its impaction. It was then suggested that the lead might be reduced in bulk by solvents, and accordingly Mr. Sheild made some simple experiments. He placed pieces of sheet lead in mercury for twelve hours, and found the lead (quantity not stated) that had been in contact with the mercury was brittle, soft, and much reduced in bulk, while the supernatant mercury was dark and lead-stained. The next day the patient's ear was well cleaned, and he was ordered to lie on his left side. The right ear was filled with liquid mercury, which was apparently retained there for sixteen hours. When the mercury ran out of the ear it was mingled with lead, being dark-coloured, and the plumbic stain was visible on the walls of the canal. A symptom of significance also was furnished by the patient, who felt the mercury run down the Eustachian tube into the throat for the first time. The following day the lead was comparatively easily removed by syringing. Scales of lead escaped, and then followed the mass, which was of irregular shape, resembling the contour of the tympanum and coated with mercury. It was reduced in bulk, and all protuberances and angular projections before visible had disappeared. Mr. Sheild's comment is that the mercury had obviously acted as a superficial solvent, had reduced the bulk of the lead and so allowed the stream of water from a powerful syringe to eject it. Treatment by liquid mercury is novel, and the possibility of employing this agent in cases of embedded balls at once suggests itself.

Unless we had seen this very interesting case it would not be possible to do full justice to it in criticism. We will merely remark that in reading the report we are inclined to emphasise the following points—(1) that the ear was suppurating; (2) that the swelling caused by the primary burns had apparently subsided but recently; (3) that no attempt to remove the lead by syringing had been made prior to the use of the mercury; (4) it is not obvious that the metal in the ear was pure lead; and (5) Mr. Sheild's statement that the mercury reduced the bulk of the metal in the ear is obviously an inference, not necessarily a fact. One of the writers of this paper (Mr. J. P. Ryan) had recently under his care at the Victorian Eye and Ear Hospital a boy aged six years, who had forced a small leaden bullet into his ear. After the primary swelling and discharge had subsided attempts to remove the shot were made by a number of methods. The shot could be felt and seen on the floor of the meatus close to the membrane. The hearing remained fairly good. All mechanical means to effect removal having failed, resort was made to the method of solution (?) by mercury adopted by Mr. Sheild. Before introducing the mercury into the ear, however, some experiments were made with a view of investigating the solubility of lead in mercury. A few pieces of sheet lead, varying in weight from six grains to forty-five grains, were placed in mercury for a period of sixteen hours, as mentioned by Mr. Sheild. They lost in that time next to nothing in weight or volume. If the surfaces are clean at the end of that period an amalgam of mercury is formed on them, and unless that is rubbed off the weight is sometimes slightly increased. If the lead is kept in mercury for from three to four days the effect is not much more pronounced. For periods of from three to four days, at all events, sheet lead is practically insoluble in mercury and consequently a considerable solution by mercury of lead impacted in the ear is impossible. The lead shot for the removal of which the use of mercury is suggested is even more difficult to deal with, inasmuch as the coating of the shot is resistant to the action of the mercury and no amalgam forms. Even if this coating is removed it makes little difference; the mercury produces no practical diminution in volume. In passing it may be mentioned that we endeavoured to effect the removal of the shot by taking advantage of its low specific gravity relative to that of mercury. The attempt to thus float the shot out resulted, as anticipated, in failure. It is obvious from these facts that in Mr. Sheild's case one of two explanations is possible: (1) Either the mercury had nothing whatever to do with the removal of the lead, or (2) the metal in the ear was not ear. On this latter point we have obtained some

information which throws a new light on the subject. There are three kinds of solder used by plumbers: (1) Plumber's solder, which is composed of a mixture of two parts lead and one part tin; (2) tinman's solder, one part lead and one part tin; and (3) pewterer's solder, one part lead and two parts tin. The plumber from whom this information was obtained is of opinion that the patient referred to in Mr. Sheild's article was using plumber's solder. If so, the matter explains itself. We have obtained plumber's solder and tinman's solder, and have made experiments with them. They are both affected by mercury more readily than lead alone. In one hour some reduction in bulk is effected. They tend to become friable under its influence.

It will therefore be of interest if Mr. Sheild will re-examine the case and ascertain definitely the nature of the metal extracted from the patient's ear and the nature of the sheet lead he used for his experiments. At present we are endeavouring to ascertain the possibility of dissolving the shot in the boy's ear by the method of electrolysis. In conclusion, we desire to express our hearty thanks to Professor Masson of the Melbourne University and to Dr. Webster for valuable assistance and suggestions.

We trust that Mr. Sheild will accept this criticism simply as an effort to obtain accuracy. The erroneous statements which, we believe, he has made, and for which there is probably a simple explanation, in no way affect the ingenuity of the treatment he adopted. The suggestion may end in a valuable addition to the knowledge required in the management of these difficult and fortunately rare cases.

*Result of some Control Experiments made for us by  
Dr. Webster.*

Substance.	Weight before Immersion.	Weight after Immersion.	Loss.	Time.
Plumber's solder...	22 gr. ...	10 gr. ...	12 gr. ...	16 hours.
Tinman's solder ...	22 ,, ...	17 ,, ...	5 ,, ...	16 ,,
Lead piping ...	17 ,, ...	15 ,, ...	2 ,, ...	16 ,,
Sheet lead ...	11 ,, ...	9½ ,, ...	1½ ,, ...	16 ,,

Thus in the same time plumber's solder lost much more than the weight lost by the sheet lead. In each case the mercury adhering to the surface was removed by rubbing before weighing. The small decrease in weight of the tinman's solder is probably accounted for by the piece being thick and of irregular surface, its thickness preventing the mercury acting freely, and the irregular surface retaining some of the mercury when the piece was weighed. The action of the mercury penetrates deeper into the solder than into the pure metal and a thin piece of the former becomes in a short time brittle and friable, contrasting with the pliability and malleability which the latter retains. When exposed to the air the solder at once acquires a silver powdery surface, while the lead retains the metallic appearance of the mercury.

THE

TREATMENT OF INOPERABLE MALIGNANT NEOPLASMS BY THE BICHLORIDE OF MERCURY IN OIL.

By R. COWAN LEES, F.F.P.S., M.B., C.M. GLAS.,  
LECTURER ON THE PRACTICE OF MEDICINE AT THE WESTERN MEDICAL SCHOOL, GLASGOW.

My attention having been drawn to an article in THE LANCET of Feb. 20th, 1892, by Professor R. von Mosetig-Moorhof of Vienna, on the Treatment of Inoperable Malignant Neoplasms by the Aniline Dyes, in which it is stated that a hypodermic injection of pyoktanin has a remarkable influence over the growth and development—nay, even the destruction by absorption—of such malignant growths as are mentioned above, I shall perhaps be pardoned if I give at this distant date my experience of the bichloride of mercury when given as a hypodermic injection in cases similar to those mentioned in the above-named article. That injections of an antiseptic nature, no matter of what kind—though I would say the less innocuous and the more powerfully antiseptic the better—will do much good I feel certain, judging from the small number of trials which I myself have had in general practice and of which the following is a short account.

In December of 1890 a tall thin man named McA—consulted me, suffering from severe dyspnoea, which on examination was found to be due to the pressure of two large sarcomatous growths, one on each side of the neck, the left being double the size of the right. His principal complaint was great difficulty in breathing, which was painful to listen to and look upon. I recommended him to visit one of our hospitals to be examined, and if possible to be operated upon, when he replied that he had been there already for a time as an in-patient, but had been discharged, with the information that nothing could be done. Hearing this I gave him a note to the laryngologist in the same hospital, requesting him to do something for the poor fellow, who was suffering so much, and who could not possibly live many days. The laryngologist sent the patient back with a note concurring with my views, both as to diagnosis and the necessity of tracheotomy, while at the same time he informed me that he had looked up the journals of the hospital and found that the diagnosis was also that of sarcoma, and that he had refused to do anything with the case. The poor fellow importuned me so much to do something for him that involuntarily I became deeply interested in his case. I informed him that at the present time no remedy was known which could effect a cure, but that he might have an operation performed which would certainly relieve his breathing, but relief was all that could be hoped for. To this he replied that he would certainly submit to anything, in order that he might get some relief in his great difficulty of breathing. Acting upon this I called upon the same laryngologist and arranged that he should perform the operation of tracheotomy, which was accordingly done the same afternoon—that is, on Dec. 27th, 1890. It is needless to say that immediate relief was experienced, and for a few days afterwards he was fed by the stomach tube with various fluid foods and stimulants combined, when he rapidly gained both strength and weight. I saw him daily up till Jan. 1st, 1891, the fifth day after the operation, then on the 8th and 12th of the same month, when he made an urgent appeal that I should now do something more for him. Explanations as to the nature of his disease and its dangerous position were of no avail in lessening his pleadings, and so I promised him that the further treatment of his case would receive my most serious consideration and thought; at the same time he was instructed to pay every attention to his dietary, and so get up his strength as much as possible.

The theory as to the cause of cancer being due to a fungus had just been propounded by Dr. Russell of Edinburgh; and thinking of the relationship of carcinoma and sarcoma it struck me that I might use an injection of bichloride of mercury in olive oil, such as I was using at the time with success in cases of pneumonic phthisis. With this end in view I made a request to Mr. John Borland, F.C.S., of Kilmarnock, who has always prepared the different forms of bichloride oil used by me in the different methods adopted in the treatment of phthisis, to make a small quantity of this oil of the strength of 1 in 2000. At the same time I had made by Messrs. Hilliard and Sons a hypodermic needle of a particular pattern, to fit an ordinary hypodermic syringe, the needle to have a solid point like an ordinary sewing needle, but with several holes at the side, so that the oil might be diffused through the tissue with less danger of its being thrown into the circulation. I then inserted the needle, fixed on to the syringe, into the very centre of the large tumour on the left side, and first moving the needle freely from side to side slowly injected twenty minims of the oil mentioned; then, withdrawing the needle carefully and placing my finger on the little needle wound, I gently placed a piece of carbolie plaster upon it and awaited the result. Within two days, to my intense surprise and delight, the shrinkage of the tumour was most marked, notwithstanding the fact that it had steadily increased since the operation of tracheotomy had been performed. The shrinkage did not continue longer than three or four days, when to all appearance it then ceased. After this I did not visit him, owing to the excessive amount of work which I had at the time, till Saturday morning, Jan. 31st, his wife having called upon me the previous night and made the request that I should give him another injection, as the first had done so much good. During my last visit—that is, on Saturday morning, Jan. 31st—he received another injection; but unfortunately it was used twice as strong as the last—that is, 1 in 1000, a strength which I was then using with benefit in the intra-thoracic injections in phthisical cases. The same night I was called to the country, where the case necessitated my remaining till Monday morning, and so was prevented from

seeing him till then, but hoped that in the interim the same shrinkage which had followed the first injection would also follow the second. My chagrin and disappointment on my return were great on learning from the doctor who had undertaken the work that great swelling and acute inflammation had set in, due probably to the excessive strength of the oil used, while the doctor, not knowing what had already been done for the patient, applied two leeches on the part and then poulticed. Suppuration set in, and the poor fellow died on Tuesday, Feb. 3rd, from sheer exhaustion, grateful at the same time for the five weeks' relief and comparative comfort which had been given him.

While this case was under my care I also adopted the same line of treatment in two cases of carcinoma of the mamma, where ulceration was present in both, but in one most markedly, having a crater-like depression in the centre, as is often observed in advanced cases of carcinoma in that region. My plan in those two cases was to cleanse a small part of the surrounding healthy skin with a solution of bichloride oil (1 in 1000) and menthol (12 per cent.), the same as I was using in the intra-laryngeal injections in phthisis. I then wiped the part nearly dry and passed the needle in from this spot into the thickest part of the growth. The needle was moved about freely, as in the sarcomatous case, and twenty minims of the oil injected (1 in 2000), while the after treatment was the same as described above. This was done twice per week for three weeks with the greatest success, when injuries from a carriage accident confined me to my bedroom for nearly three weeks, after which I did not make any further investigations, owing to the great difficulty experienced in general practice of securing proper observations in such cases. What had been done in the three cases, however, taught me, even although not one of them had been brought to a successful termination, that a powerful check, if not a complete remedy, existed in the injection of bichloride of mercury in olive oil, and I would beg to recommend to anyone holding a hospital appointment a trial of the above-mentioned treatment, where under more favourable circumstances proper observations of the cases could be taken and measures thoroughly carried through.

Glasgow.

## SYPHILITIC INSANITY.

By A. H. NEWTH, M.D. ABERD., M.R.C.S.

THE study of cerebral syphilis is one of interest and importance, but it is a subject that has received more attention from continental than from English physicians. The disease is of interest because it presents many curious symptoms, and is very closely allied to general paralysis of the insane. It is important to be able to diagnose it, as in the early stages of the disease it is fairly curable, or at any rate the progress of the complaint may be checked for a considerable time by appropriate treatment. Many differences of opinion are held on the subject of cerebral syphilis, some observers thinking it has no specific significance, whilst others believe that syphilis is the sole cause of general paralysis of the insane. There is a very close resemblance between this latter disease and syphilitic insanity, so much so that the one is frequently mistaken for the other. The diagnosis, however, in most cases is not difficult if special care is taken in studying the history of the case and observing the symptoms. There are, on the other hand, cases so pronounced in similarity as to make the diagnosis extremely difficult, if not impossible. Syphilitic insanity frequently is associated with general paralysis, the latter disease developing after the former has shown itself for some time. As general paralysis attacks individuals who are given to venereal excess they are often the subjects of syphilitic infection.

Syphilis of the brain or nervous system is very variable in its development and characteristics. The nervous symptoms, as a rule, do not correspond with any special lesions of the brain or spinal cord and it is this want of coincidence that is one of its peculiarities. Whilst most cases of insanity may be traced to some remote or proximate cause, syphilitic insanity arises without any special cause, though sometimes

an injury, as a fall, blow on the head, sudden shock &c., may act as an exciting cause and start the disease into activity. A sudden and severe attack of nervous symptoms in a person previously apparently healthy affords a very strong presumption that these symptoms are due to syphilis. The erratic character of the symptoms and their abrupt development are two of the most characteristic features in syphilitic insanity.

It is always most difficult to obtain a definite history of syphilis from any patient; and as syphilis of the brain may not show itself for some years, even so long as sixteen years, it is still more difficult in this disease to elicit any account of infection. In many cases, however, the patient may show signs of syphilis. For instance, there may be indented teeth (Hutchinson's), effusion of lymph and formation of vascular nodules in the iris; perforation of the palate; copper coloured eruption; nodes on the long bones; syphilitic ulcers on the legs; signs of buboes, chancres &c.; irregular patches of baldness; linear scars running outwards into the cheeks from the corners of the mouth; a broad sunken nose, &c. He may have suffered for some time from periosteal headaches or neuralgias which were worse at night. There may also be a history of frequent faintings or vertigo, slight convulsive seizures, a want of power in using the limbs &c. He may have shown some instability of character, fits of unreasonable passion, defective memory, errors in speaking or writing—that is, using wrong words to express his meaning, omitting certain words or letters in writing, and a lack of faculty for business.

The following case will afford a good idea of what may be regarded as a very early stage of syphilitic disease of the nervous system:—The patient, aged forty, was a man in whom there was no evidence of syphilis, although there was some slight hereditary history. When the patient came under my care he was not insane but he had the insane neurosis. He was indeterminate in his actions, unstable, and frequently showed a want of coherence in his conversation and writing. His memory was defective and he had partial amnesic aphasia, often using the wrong terms to express his meaning and omitting words or letters, or misplacing them in his writing. He was somewhat deaf and myopic. His temper was most irascible; he would give way to unreasonable outbreaks of violent language and find fault without cause. He had a morbid sensitiveness to what others might say or do as regarded himself, taking offence at imagined slights or insults. At times he had a great idea of his self-importance, at others he was depressed and self-depreciatory. He frequently had slight convulsive seizures and attacks of giddiness and faintings; he walked lamely or awkwardly. He complained of confusion of ideas and a want of power to concentrate his thoughts on any given subject, and suffered from severe headaches, worse at night. He was placed under appropriate antisiphilitic treatment for some months, and eventually recovered his usual health. He is now able to write and speak fluently and to successfully carry on his work. This case would most probably have developed into syphilitic insanity had he not been placed under treatment in time.

A person suffering from syphilitic insanity has a peculiar imbecile expression; his appearance is flabby, flaccid, vacant. Though his eyes are staring he does not seem to notice anything with attention, and will not look at the person who is speaking to him in a straightforward manner. He has a slouching manner of walking; often his gait is uncertain, shambling or staggering, and he often has a tendency to fall if not supported. Sometimes he walks like a person affected with paralysis agitans; occasionally he gives a little jerky run and then stops.

The patient generally complains of giddiness or vertigo, may be subject to attacks of syncope and frequently there are slight or even severe apoplectic seizures, sometimes accompanied by hemiplegia and followed by an epileptic or semi-epileptic state. These epileptic attacks, which are often the first expression of the disease, differ from ordinary epilepsy; they are not so general, the patient is mostly conscious during the fits or can be affected by external stimuli, and may be able to record what took place whilst he was under them. The spasms affect chiefly such muscles as the biceps and recti, and are not so tonic as in true epilepsy; there is more of a quivering of the muscles and the spasms are somewhat intermittent. There may be strabismus, ptosis, contractions of the facial muscles &c. from affections of the intra-cranial nerves. Partial or complete paralysis of the extremities is not

uncommon. These paralyzes are peculiarly inconsistent in their character—that is, they do not seem to coincide with any special cerebral lesion. They are generally unsymmetrical; there may be, for instance, facial paralysis on one side and ocular motor paralysis on the other; or ptosis of one eyelid and paralysis of the abducens on the other; or aphasia may be coincident with left hemiplegia. These paralyzes are not always permanent, they very often shift and change in a peculiar manner; in fact in many points they closely resemble hysteria. The symptoms are rather disturbances of coördination and high degrees of weakness, which have been described by Dr. Hughlings Jackson as a "paralysis of energy." Locomotor ataxia is not an uncommon result of syphilis, but has then the peculiarity of being liable to remissions; and it is frequently observed that as the mental disturbances subside the ataxy increases or develops, or the converse may take place. Dr. Hughlings Jackson lays great stress on the importance of examining the fundus oculi whenever a patient has nervous symptoms, and especially if he has pains in the head. Optic neuritis is a strong evidence of cerebral mischief, and this with one-sided convulsion is, according to Dr. Buzzard, a very diagnostic feature in syphilitic disease of the brain. Dr. Stretch Dowse describes the ophthalmoscopic appearances in cerebral syphilis as being neuro-retinitis, choroiditis, and optic atrophy. The first, he says, is commonly observed, the second is an almost undoubted indication of old-standing syphilis, whilst the third is common to syphilis and general paralysis. Syphilitic amaurosis is not uncommon, sometimes there is double vision, and deafness is very frequently met with.

*Mental symptoms.*—The first observable mental symptom is loss of memory, especially for recent events. This loss of memory does not arise so much from actual amnesia as from a confusion of ideas, or an inability to collect the thoughts and concentrate the attention on what is said. It may also be due to a want of power to reproduce received ideas, or a paralysis of mental energy. There is a lack of æsthetic feeling and the ethical or moral sentiments are wanting in expression, syphilitic patients being often most obscene in their behaviour and regardless of the decencies of life. The intellectual faculties are dormant, not entirely wanting in receptivity or expression, and the innate or cognate ideational faculties are simply torpid. During sleep, or an apparently deep sleep, the intellectual faculties may act in a remarkable manner, strikingly different from the hesitating imbecile way that ideas are expressed when the patient is awake. Though, as a rule, there is a state of mental vacuity, passing into stupor or even coma, there may be attacks of mania, senseless ravings, irritability of temper, and total change of disposition. The patient often appears hysterical, laughing at one moment, crying at another. If there is furious mania, which sometimes occurs after an epileptiform or apoplectic seizure, it is the mania of impotence. Dr. Hughlings Jackson says: "A random association or a random succession of nervous symptoms is a very strong warrant for the diagnosis of syphilitic disease." In many cases there are grandiose ideas, as in general paralysis of the insane, but this monomania of grandeur is not so pronounced. In fact, the mental symptoms are not definite as regards any special feature. It is this want of coincidence in the mental symptoms, as in the paralyzes, that strongly characterises syphilitic disease of the brain. As Professor Heubner describes it: "The half and half incomplete nature of the severe symptoms, the impairment of the consciousness without its entire destruction, the loss of voluntary activity without the complete abolition of voluntary impulse, the half awake and half dreamy condition of the patient," are strong peculiarities of syphilis.

Often patients have a loss of power to express particular words or even letters or numbers. They will speak or write up to a certain point correctly and then stop unable to proceed, or they will be unable to give expression to particular things or ideas though they may be well able to recognise them, or they will transpose ideas, words, or letters in a strange way. Delusional insanity may be due to syphilis. Patients suffering in this way are very suspicious, fancy unseen agencies are plotting against them and take all manner of strange precautions to ward these off; sometimes acting on these delusions they become very dangerous. They will imagine they are the victims of diabolical intrigue from persons who follow them about and endeavour to get rid of them for some occult purpose either by actually killing them or persuading, or, as it were, irritating them to commit suicide. They will hear "vocalisation" or fancy voices are speaking to them when no one was near, or those who were near have been

perfectly silent. Dr. Clouston gives several very interesting cases of this form of syphilitic insanity. He also mentions the case of a clergyman who, twelve years after syphilitic insanity, conducted himself most obscenely towards the female members of his congregation. Of a medical man who, though otherwise able to conduct his practice well, misconducted himself towards young girls. Both of these had to be placed under treatment in an asylum. He graphically and concisely describes a case of syphilis of the brain in the following terms: "Mentally a change of character, morbid suspicions, loss of self-control and of the moral feelings, a disregard of the decencies of life, then an intense irritability, often with violence and a loss of memory, then an enfeeblement of the mental power, ending in complete dementia. Bodily, an unhealthy and cachectic general state, a lack of trophic power, with no cephalalgia necessarily, then a failure of muscular power and a tendency to partial paralysis, then occasional epileptiform fits, sometimes unilateral, but never more localised than a motor paralysis that advances and recedes in a puzzling way; then a loss of power over the sphincters, loss of trophic power and death, if that has not occurred before through an attack of convulsions." Though this is tolerably correct the sequence of the symptoms is not always exactly as Dr. Clouston describes them.

The treatment necessarily resolves itself into antisypilitic remedies; these, if judiciously and early administered, do great good. Professor Wunderlich says: "We must not use our therapeutic agents timidly, and need not wait for the complete evidence of the syphilitic nature of the affection. We can never do any harm with the inunctions or iodides, and if it turns out that the patient is syphilitic we shall then save him."

Dr. Clouston gives several cases of syphilitic insanity cured by specifics, and numerous other physicians have done so also. I have frequently met with most encouraging results from the use of mercury and iodide of potassium even in apparently hopeless cases. I generally prefer first of all to give mercury, either the bichloride by the mouth or mercurial inunctions for, say, one week, then a course of sodium or potassium iodide for about another week, and afterwards a few days of arsenic. Returning again to the mercury and iodides. This method of administering these three drugs I prefer to giving Donovan's solution, as it seems far more efficacious. Treatment must be persevered in, even though the disease seems to have subsided, for it is a peculiarity of syphilitic disease of the nervous system to have remissions; sometimes the disease seems to pass away without treatment. It will, however, nearly always recur soon, but the succeeding attack will differ either in its nature or in its seat. The pathology of cerebral syphilis is very interesting, but however much I should like to touch on it, I have already exceeded the limits of my paper. The purpose I have had in view has been simply to draw attention to a few facts on a subject which does not receive the attention its importance merits.

Hayward's Heath.

## VASO-MOTOR NEUROSES.

By W. BOLTON TOMSON, M.D. DURH., L.R.C.P. LOND. &c:

I HAVE selected the following from a considerable number of allied conditions seen and noted, as they seem to form a somewhat definite series, and to illustrate what I believe to be an extensive section of functional disorders—namely, local and general vaso-motor neuroses. To try to prove that my cases are truly neurotic affections I am obliged to first briefly enumerate the salient features of this class of disease in order to show by a prominent comparison that they are similar in kind. Neurotic patients abound in all highly cultured communities. From the standpoint of the evolutionist, instability of the highest nerve centres is due to their being the most recently evolved, and is therefore a necessary evil accompanying an intellectual advancement.<sup>1</sup> The subjects of epilepsy, hysteria, migrain, flushing and morbid blushing, hay fever, paroxysmal drink craving (for I assume this to be a neurosis), and, speaking generally, neurotic people, are not

<sup>1</sup> See Hughlings Jackson, Croonian Lectures, Brit. Med. Journ., March 29th, April 6th and 12th, 1884. Other writings include: Remarks on the Evolution and Dissolution of the Nervous System, Journal of Mental Science, April, 1887; and Remarks on Evolution and Dissolution of the Nervous System, No. 1 (John Bale and Sons, London, 1888).

dull and stupid—they are often keenly intellectual; but, like visible peculiarities of form, feature, and action, intellectual weakness has been transmitted with intellectual strength. Examining more closely, however, we see that although certainly in many instances the same disease has been transmitted, it also, perhaps with equal frequency, happens that another of the same class is the representative of the faulty habit. A parent has megrim, the child epilepsy. The child of the epileptic may suffer from paroxysmal drink craving, and I have known the sister of such a drunkard who possessed so unstable a nervous system that her face would often assume an almost death-like pallor as any stranger approached the counter at which it was her daily occupation to serve. In the cases of hysteria major described by Charcot<sup>2</sup> we find such conditions as epilepsy, drunkenness, hysteria and other diseases of the same class in the family histories of the patients affected. From these facts it would appear that it is not so much a definite disease as a faulty nerve habit, a neurotic tendency, that is transmitted, and that the tendency may produce any one of the diseases that belong to the same class. Nerve storms and faulty habits of all kinds have for their exciting cause any profound mental emotion, as disappointment, fear, love, fright, excitement, shock. Summarising, then, the distinguishing features of this group of disease we notice the intellectual calibre of the patient—the hereditary transmission of a *tendency* rather than a definite disease, and that any depressing mental emotion may be an exciting cause. As types or subdivisions of the class we see that in epilepsy the most prominent symptoms are motor; in megrim sensory, and affecting special senses; in morbid blushing vaso-motor. It is to the last subdivision that I refer the following.

CASE 1.—Mr. —, aged about thirty. Good physical health; average intelligence. Family history: Grandfather and grandmother, about whom very little can be ascertained, had five sons: *A* possessed small private means, never followed any occupation, but led a solitary and very eccentric life; *B* good mental ability, liable to periodic outbursts of ungovernable passion, vain, self-conscious; *C* good mental power, passionate; *D* great ability, rose to a prominent position; *E* weak intellect from birth, never able to manage his own affairs. *C* had two children: (1) a son, my patient, (2) a daughter, quick perception, liable to attacks of passion without any obvious external cause; for some time hysterical, with a tendency to anorexia nervosa. *D* had five children, of whom the second, a son, died of general paralysis. The third, also a son, had very small private means; would follow no occupation; took small apartments away from his family and lived alone. With this family history my patient has a tendency to shun society and lead a solitary life. He is subject to attacks of morbid blushing. These may last a few days only and be followed by periods of good vaso-motor control. He also—and it is to this I wish to draw attention—finds it impossible to be confined in a room for any length of time without the possibility of egress, as in the compartment of a railway carriage. It would be certain to produce diarrhoea, with watery evacuations. If the carriage contained a lavatory the desire would not be induced.

CASE 2.—This case is very similar in character to the last. The patient also belongs to a highly nervous and excitable family. He cannot bear to be confined in a room for any length of time without being able to easily get out. The effect on him is that large quantities of pale urine are secreted and he is seized with the desire to micturate. In neither of these cases can any disease of the bowel or kidney be discovered. The secretion of urine, it must be remembered, is a double process, consisting partly of a formation of urinary constituents by the epithelial cells of the kidney and partly of a filtration by which water is removed from the blood.<sup>3</sup> Since my patient (Case 2) passes quantities of pale clear urine it is safe to argue that it is due to an increase of blood pressure from a temporary dilatation of his renal arteries.<sup>4</sup> In the same way I consider the watery evacuations from the bowel to indicate a temporary dilatation of the intestinal vessels. The special inference that I wish to draw from these cases is that this dilatation is the direct result of a vaso-motor neurosis affecting the cerebral centres that exercise a vaso-motor control over these particular areas. Let an expectant attention be fixed on any superficial or deep area, and if the patient be neurotic, to that area the brain, against its own inclination, will direct the vaso-motor storm. I do not

believe it is because the face is uncovered that it blushes, but because the brain knows it to be uncovered and therefore conspicuous. So far, the sympathetic effect on the vascular system has, according to my argument, been transitory. I pass on to conditions of a more lasting character.

CASE 3.—Miss —, aged fifty-eight. Mother subject to periodic headaches; father had asthma. Patient has never menstruated. Apart from the attacks of megrim she is healthy. She is a very thin woman and is constantly blinking. Ever since she can remember she has suffered from megrim. During the last ten years the attacks have been much more severe. They come on with great regularity once a week, on Sunday night or on Monday morning between 4 and 5 o'clock. The symptoms consist of visual sensations in the form of black spots or bright colours, apathy and languor, flushing of the face, violent hemicrania, retching or vomiting, and then improvement. Accompanying every seizure there is a most perceptible beating of the aorta in the region of the coeliac axis. Pulsation can always be readily felt in this position, but during the megrim it is markedly exaggerated. There are no symptoms or physical signs of aneurysm, and there appears to be no doubt that this is a periodic dilatation of the aorta in this position. This patient was seen and this diagnosis corroborated by Dr. Sharkey.

The next three are cases of paroxysmal palpitation of the heart without organic disease, occurring in hysterical patients.

CASE 4.—Mrs. —, aged thirty. A brother of this patient is subject to attacks of fainting without apparent cause. Before marriage she was sometimes hysterical, crying and laughing hysterically; otherwise she was healthy. Present illness commenced about eighteen months ago, after the birth of her second child. She was just thinking of getting up when she had a sudden violent attack of palpitation. Since then she has been liable to similar attacks. They come on with any emotion or fright, as the slamming of a door, or talking to a stranger, often without any apparent cause. If she were to walk far she would feel exhausted, and might have an attack. Sometimes these attacks last a minute or so, sometimes an hour. They are attended with various sensory symptoms, the most frequent and pronounced of which are giddiness, shivering and sensations referred to different parts of the body which she finds it difficult to describe. She is very liable to headaches and neuralgic pains over the right temporal region. Attacks sometimes occur at monthly times, but often between the periods. There are no systemic symptoms or physical signs of heart disease. When the heart feels to her to be beating quietly the rate is about 108 per minute and regular. During the attack it reaches 180 to 200 per minute.

CASE 5.—Mrs. —, aged thirty-eight, says she has had good health, but has always been hysterical, especially at monthly times. Family history doubtful, as parents died in Florida when she was young. The patient has had two children. She swallowed a pin six months ago. It caused her great anxiety, and one week afterwards she had the first attack of heart palpitation. She never suffered in this way before. It was quite a month before the second attack came on. She was then very hysterical. Since that time she has had similar seizures at intervals of two or three weeks. They are worse if they occur near the catamenial period. The attack generally commences with a twitching about the limbs; she then becomes hysterical, crying and shouting, and the heart beats very hurriedly. She has not had hysteria without palpitation for the last six months, but has often had palpitation without hysteria. The heart during an attack beats 140 to 160 per minute, sometimes more. There is no evidence whatever of organic heart disease. This patient was also seen, and the diagnosis confirmed, by Dr. Sharkey. These attacks almost always come on at about the same time in the evening, between seven and eight o'clock; and after the attack the patient generally passes a quantity of urine, pale and of low specific gravity.

CASE 5.—Miss K—, aged thirty. The family history was not reliable. She suffered from attacks of palpitation of the heart and a slightly irregular beat. There was a uniform soft enlargement of the thyroid, but no other symptoms of Graves' disease. She came to see me for a typical hysterical aphonia, which was completely cured in the course of a few weeks by applications of the interrupted current.

These three cases very well illustrate a condition by no means rare—namely, attacks of palpitation that often date from a shock or profound mental emotion—the patient being neurotic. Evidence of the neurotic tendency is afforded by the frequent association of hysteria. It is also here interesting to notice that in Case 5 the attacks exhibited the same

<sup>2</sup> Diseases of the Nervous System, vol. iii., lect. xviii. and following.

<sup>3</sup> Foster: Physiology, Book II., Chap. iv., Sec. 2.

<sup>4</sup> Ibid.

tendency to periodicity that is so constantly seen in megrim. I have no intention of implying that all who suffer from paroxysmal heart hurry are neurotic, but that a percentage of neurotic people show their tendency in this form. Another illustration of what I consider to be a vaso-motor neurosis giving rise to arterial dilatation of a limited nature appears to me to be afforded by the numerous cases that are seen of enlargement of the thyroid with the following characteristics. The patients are generally young, highly nervous women, belonging to families with a marked nervous tendency. The condition is generally, but not always, associated with cardiac palpitation coming on in attacks. The swelling is not great; it is soft and uniform in outline. It may, and often does, vary considerably in size at different times, or remains enlarged for a limited period only. Such a condition may be associated with hysteria, and I have under treatment at the time of writing a patient with cardiac palpitation and this form of thyroïdal enlargement who has suffered for many years from attacks of megrim coming on every Sunday. Corroborative evidence appears to me to be afforded that this form of swelling of the thyroid is due to arterial dilatation by the following case:—

CASE 7.—Miss —, aged twenty-seven. Her mother is very excitable and nervous, and suffers very much from indigestion. She has a sister who is also of a highly nervous temperament and who suffers from an "enlargement of the throat." Catamenia commenced at seventeen. It was always irregular and accompanied by pain. She has had attacks of palpitation of the heart ever since she can remember. Sometimes on exertion, but just as often when she is sitting quite still; the heart seems suddenly to give a bound and then continues to beat very quickly. She tells me that three weeks ago, at a monthly period, a swelling suddenly appeared on the right side of the neck. She had a considerable fullness of the neck for some time previously to this, but does not think the lump could possibly have been there before and undiscovered. It was not attended by any pain. On examination there was a soft uniform enlargement of the thyroid, and on the upper right lobe there was a round, smooth, fluctuating swelling about the size of a walnut; no redness; no skin adhesions. This swelling was punctured with a hypodermic needle and proved to be a sero-sanguineous cyst. The pulse on March 11th, 1892, was 130 per minute, and on March 13th 120. There were no systemic or physical signs of heart disease. It must be remembered that at the catamenial period the general blood pressure is raised, and the tendency to rupture of capillaries and small vessels of any area would be increased by a dilatation of the arteries of that area. Consequently these cases of sudden formation of sero-sanguineous cysts occurring at a monthly time in patients with the condition of thyroid that I have described corroborate the view that the enlargement is due to dilatation of the thyroïdal arteries. I have seen three cases exactly similar to this. It has long been known that some internal organs, notably the kidneys, vary considerably in size from time to time, according as their arteries are dilated or contracted by vaso-motor influences.<sup>5</sup> Dr. T. Savill tells me that when attending Professor Charcot's clinique he saw exhibited several cases of transitory redness of the hands and forearms occurring in hysterical patients. He also refers me to the account of "Bluc Edema of Hysterics."<sup>6</sup> Here the author describes a condition in which a part of the body becomes cold and cedematous, but does not pit easily on pressure. In appearance it is bluish or cyanotic. Sensation is lost or exaggerated. Charcot considers the symptoms to be entirely due to a vaso-motor disturbance, probably spasmodic in character. Both these conditions afford interesting illustrations of neurotic patients with a loss of vaso-motor control over definite and limited areas.

The preceding cases have naturally led me to the pathology of goitre exophthalmos. The symptoms seen in the cases I have described have merely consisted of a few of those found in that disease; and, if my explanation is correct—that in them vaso-motor function has been modified in some limited area—then surely Graves' disease is a general neurosis in the truest sense, for it must be an almost universal derangement of the vaso-motor system. Analyse the symptoms by this view and the explanation of them seems rational. A neurotic family tendency may sometimes be found in the form of hysteria or epilepsy, or the disease may seem

to be directly transmitted. It is far more prevalent in women than men, and Dr. Gowers says that "no immediate cause is so frequent as a depressing emotion." Only just recently a lady, a relative of my own, saw a case in a hospital ward, and was shortly after seriously affected with the same disease. The flushing and the sweating are positive proof that vaso-motor disturbance does take place. Pigmentation of the skin may show itself in any form of skin hyperæmia. Moreover, in a patient affected with goitre it varies considerably from time to time, as one would expect if it be dependent on hyperæmia that varies. In one old patient that improved considerably from the application of electricity to the neck, as described by Mr. Cardew in THE LANCET of July 4th and 11th, 1891, large patches of pigment began to disappear from her legs directly she commenced to get better. I am at the present time attending a male patient who volunteered the question, "Why is it that brown patches frequently show themselves on my arms, last a few days, and then disappear?" Polyuria may certainly occur as a direct result of the dilatation of renal arteries, and diarrhœa may possibly in a similar manner depend on a dilatation of the arteries of the bowel, as was suggested to explain Cases 1 and 2. Moreover, as the bladder fills with this clear pale urine the same inability to hold it may sometimes be witnessed. A child with incomplete Graves' disease constantly wetted the bed. Another patient, a woman with the disease well marked, would suddenly eject urine with great force on to the floor. The thyroïdal enlargements may be due to arterial dilatation, as I have already argued, and the protrusion of the eyes to a similar dilatation of the mass of bloodvessels that comprise nearly the whole of the choroidal structure. This exophthalmos reminds one forcibly of flushing of the face. It may affect one side only, as it did in the case of my own relative and it often varies considerably in degree at different times. Increased pulsation in the arteries is sometimes seen, as in Case 3; and how frequently we see a pulsation in the temporals of neurotic women. I have described cases of heart hurry in a previous part of this paper that seem clearly to be functional and due to sympathetic derangements. The same explanation seems equally applicable here. The irregularity may be because the sympathetic stimulus resembles a constant current occasionally made and broken, or else that variations in the vaso-motor control of different areas about the body upset the rhythm of the heart by rapid modifications in peripheral resistance. Lastly, there is a tremor, an indicator *par excellence* of a highly nervous state, witnessed frequently in the subjects of flushing and morbid blushing.<sup>7</sup> The fact is easily verified by observation. My own experience is that there are patients like Case 1, in whom vaso-motor control varies, being sometimes fairly good, at others strikingly bad. The periods of weak control are always attended by a marked tremor. Those who agree with the dictum of Hughlings Jackson, that "all parts of the body are represented in the highest cerebral centres," will not consider it unreasonable to assume that the same mental condition that can and so often does produce transitory vaso-motor storms in the form of morbid blushing may similarly and with equal frequency affect other centres governing deeper structures and internal organs, nor that the effect may be transitory or lasting, just as the functional conditions affecting motor and sensory nerves may be transitory or lasting. According to this view the cases I have described vary in degree and extent, but not in kind, and differ from one another only in so far that different vaso-motor areas are involved.

Luton, Beds.

PRIZE ESSAY ON RICKETS.—John Strahan, M.D., Belfast, has been awarded the Triennial Warren Prize, value 500 dollars, given by the General Hospital, Massachusetts, U.S., for a treatise on "Rickets." The prize was open to competition by the world and the subject left to the candidate. The prize was to be withheld if no essay of sufficient excellence submitted. The treatise will be published shortly. In 1886 Dr. Strahan gained the Fothergill Gold Medal of the Medical Society of London for an essay on "Typhoid Fever," and in 1889 the Jenks Memorial Prize of 250 dollars given by the College of Physicians, Philadelphia, for an essay on the "Diagnosis and Treatment of Extra-uterine Pregnancy," for which he was also elected Corresponding Member of the College.

SHORT NOTE OF A  
CASE OF DOUBLE OVARIOTOMY DURING  
PREGNANCY.

By EDWARD COTTERELL, F.R.C.S. ENG.,  
SURGEON TO OUT-PATIENTS, LONDON LOCK HOSPITAL, ETC.

THE small number of cases of double ovariectomy during pregnancy hitherto recorded has prompted me to bring under notice the following case.

M. P.—, aged thirty-seven, multipara, a poor half-starved woman, consulted me about the beginning of March, 1890. She stated that she was three months pregnant, but that her abdomen was larger than it was usually at full term. She also complained of very great abdominal pain. Physical examination revealed an abdominal tumour, probably ovarian, which appeared larger on the left side, but which extended well on to the right side. There was evidence of a small amount of fluid in the peritoneal cavity together with an enlargement of the uterus, this latter being probably due to pregnancy. An operation was advised, which after some delay was agreed upon. On April 5th, 1890, I opened the abdomen and removed a large multilocular ovarian cyst connected with the left ovary. There was some difficulty in doing this, owing to a large number of old and recent adhesions. It was then discovered that there was another large multilocular cyst, also very adherent to the surrounding parts, growing from the right ovary. This was removed. The uterus was found enlarged. The operation was performed antiseptically, the spray not being used. A Keith's drainage-tube was inserted. The patient suffered severely from shock for about three hours, after which she rallied remarkably, considering her weak state before the operation. Forty-two hours after the operation the patient aborted a four months' foetus; after which she quickly became moribund, and died in about three hours. A post-mortem examination showed no evidence of peritonitis.

The following table of cases of double ovariectomy during pregnancy is taken by permission from Mr. J. Bland Sutton's "Surgical Diseases of the Ovaries and Fallopian Tubes," to which I have added my own case and one recorded by Stratz:—

Operation.	Stage of Pregnancy.	Nature of Tumours.	Result.	Place of Record.
Thornton.	Fourth month.	Dermoids.	Recovered; pregnancy went to 8th month.	Trans. Obst. Soc. Lond., vol. xxviii., p. 41.
Mundé.	Fifth month.	Dermoids.	Miscarried 72 hours after operation; recovered.	American Journ. of Obstetrics, vol. xx., p. 730.
Potter.	About fourth month.	Not stated.	Recovered; delivered of a child 5 months after operation.	American Journ. of Obstetrics, vol. xxi., p. 1028.
Montgomery.	Third month.	Removed both ovaries.	Recovered; pregnancy went to term.	American Journ. of Obstetrics, vol. xxi., p. 1084.
Bantock.	Third month.	Dermoids.	Recovered; pregnancy went to 8 mths.	Journal of the Gynecol. Soc. of Great Britain, vol. vi., p. 4.
Meredith.	Third month.	Papillomatous cysts.	Recovered; went to term.	Trans. Obst. Soc. Lond., vol. xxxii., p. 374.
Meredith.	Third month.	Dermoid and multilocular cysts.	Recovered; went to term.	Unpublished.
Stratz.	Third month.	Not stated.	Recovered; no subsequent record.	Zeitschrift für Geburtsh., Bd. v. 1880, p. 385.
Cotterell.	Fourth month.	Multilocular cysts.	Aborted 42 hours after operation; death.	Reported above.

NORTH-EASTERN HOSPITAL FOR  
CHILDREN.

ILEO-CÆCAL INTUSSUSCEPTION; INJECTION OF WATER;  
LAPAROTOMY; RECOVERY.

(Under the care of Mr. BILTON POLLARD.)

THIS case presents some unusual features which render its publication of importance. There are now many examples known to the profession of successful operation for intussusception in children, and it is agreed that in some it is the only treatment likely to prove of use, and we have no doubt that if abdominal section had been more frequently resorted to within a reasonable time after failure of the injection of air or fluid more lives would have been saved. Mr. Pollard points out that inflammatory swelling of the walls of the bowel may simulate a continuance of the intussusception, but this is such an unusual occurrence that if with this abnormal swelling there is frequent mucous discharge from the rectum few would hesitate to operate. It is now more fully recognised that the abdominal exploration is not of itself dangerous when the case has not gone too far. For the notes we are indebted to Mr. R. A. Dunn, late senior house surgeon.

A. H.—, a male child, aged six months, was admitted under the care of Dr. Turner on Jan. 11th, 1892. About 10 P.M. on the previous day the bowels acted. At 6 A.M. the child, waking up suddenly, began to scream and vomited. It had vomited three times since and had had many fits of screaming. At 9 A.M. blood and mucus were first noticed on the diapers, but neither motion nor flatus was passed either then or since. On admission, ten hours after the onset of symptoms, the child's abdomen was tender but not distended. An indefinite swelling was felt in the right loin, but no tumour could be detected by rectal examination. The child was put under the influence of chloroform and then a very distinct sausage-shaped tumour could be felt in the right loin. A pint of water was injected by means of a tube and funnel, which was raised about two feet above the abdomen. As this failed to remove the tumour the injection was repeated. During both injections only the descending and transverse portions of the colon could be felt to be distended; but after the second the tumour seemed to disappear and could not be felt till an hour later.

At 9 P.M. (fifteen hours after the onset of symptoms) Mr. Pollard examined the child under chloroform and felt a tumour just about the hepatic flexure of the colon. Another pint of water at a temperature of 100° F. was injected, but this time the funnel was raised to a height of three feet and a half. The descending and transverse portions of the colon became tensely distended and the tumour disappeared, but the ascending colon and the cæcum could not be felt to be distended. An hour later a little cylindrical swelling, smaller than the one which had previously been felt, was found just above the right iliac fossa and just to the right of the linea semilunaris. At times the tumour seemed to disappear, but presently it returned. Mucus was still being passed from the rectum. Believing that a small portion of the intussusception was unreduced, Mr. Pollard explored the abdomen through a median incision commenced just below the umbilicus and carried downwards for two inches. On examining with the finger the tumour was at once felt. It was drawn out through the wound. The cæcum was congested and swollen, but there was no intussusception. The little tumour which had been felt was situated at the junction of the ileum with the cæcum. It had a cylindrical shape and could be moved to and fro for a little distance within the gut, to the interior of which it appeared to be fixed all round. It seemed to consist of the ileo-cæcal valve, which was much swollen. The gut was quickly replaced and the wound closed. The operation

caused very little shock. The child was fed by the spoon during the night and no opium was given. The temperature rose to 100·8° the day after the operation, but fell in the evening, and did not afterwards go above 98·8°. On the day after the operation the child appeared comfortable. The discharge of blood and mucus had ceased. The bowels acted for the first time on the third day after the operation; the stitches were removed on the ninth, the wound being healed, and the child was sent home on the thirteenth day after the operation. A week later the child was still quite well.

*Remarks by Mr. BILTON POLLARD.*—There was no doubt about the nature of the case, for the symptoms, as well as the lump which could be felt, were so characteristic of ileo-cæcal intussusception. The pressure of two feet of water failed to reduce the intussusception, but a pressure of three feet and a half undoubtedly did so without causing any damage to the intestine. The readiness with which the swollen ileo-cæcal valve could be felt through the abdominal wall is interesting. That the little lump really was the valve seems incontestable; it certainly was not a small intussusception, for it was just the same size and shape both before and after it had been withdrawn from the abdomen. It certainly was not a faecal mass, and it did not feel like a polypus. It is always very difficult to be sure whether an intussusception has been reduced by injections; the invagination is nearly always partly reduced by these means, but time very frequently shows that complete reduction has not been effected. In this case the injection had succeeded, although it was thought to have failed; but the laparotomy, which was quickly done, at once settled the doubt which was felt about the point without causing much additional shock. Perhaps it would be wise to perform laparotomy in all cases in which any doubt existed as to complete reduction when an hour had elapsed after the employment of water pressure, for surely less harm would be done by that operation than would result from leaving an intussusception unreduced until the lapse of time showed clearly that such was the case.

### LIVERPOOL ROYAL INFIRMARY.

POST-PHARYNGEAL ABSCESS; ASPHYXIA; LARYNGOTOMY;  
RECOVERY.

(Under the care of Dr. DAVIDSON.)

THE necessity for laryngotomy for the relief of a condition such as that described below does not often arise in the adult, in whom retro-pharyngeal abscess is comparatively rare. Mr. Davies points out the following, which appear to be of greatest interest in the case: 1, The original error of diagnosis; 2, the bursting of the abscess and the consequent flooding of the larynx with pus; 3, the resuscitation from apparent death by artificial respiration after laryngotomy; 4, the abscess occurring in the tissues behind the pharynx and the vertebrae not being affected; 5, the probability that the lesion which must have existed in the nasal cavity to account for the epistaxis afforded a suitable surface from which septic matter was absorbed, producing inflammation and subsequent suppuration in the prevertebral lymph gland, into which the lymphatics of the posterior nares open. We are indebted to Mr. P. E. Davies, house physician, for the account of this case.

J. B. S.—, aged forty, a master mariner, was sent to the hospital on the night of Aug. 29th, 1892, at 11 P.M., supposed to be suffering from acute tonsillitis. On examination the patient had an anxious expression, a pale face, and appeared to be suffering pain. The voice was nasal in character, and speaking increased the pain; the breathing was hurried but not embarrassed. The neck appeared normal, no tenderness or enlarged glands were found on palpation. An ineffectual attempt was made to examine the throat owing to the patient's inability to open his mouth and his very irritable state. He was sent to bed, and a mixture containing salicylate of soda, in ten-grain doses, was ordered to be taken every three hours. Half an hour afterwards, on arriving in the ward in response to an urgent call, Mr. Davies found the patient in a moribund state. The respiration had ceased, the eyes were staring, the pupils widely dilated, there was no conjunctival reflex, the face was livid and the pulse could not be felt at the wrist. This condition came on after an attack of "choking," following his attempt to swallow the first dose of medicine. Laryngotomy was immediately performed,

artificial respiration resorted to, and after three or four minutes breathing was restored, but the patient remained in a very collapsed state for some considerable time. During the performance of artificial respiration pus mixed with mucus was observed escaping through the tracheotomy tube, and altogether about two ounces were coughed up through the tube and mouth during the night. On the following morning at about 11 A.M. an examination of the throat was possible. The tonsils were found normal, but in the middle line of the pharynx, and extending more to the right than to the left, was an inflammatory swelling discharging pus through a small opening. On introducing the finger no irregularity or thickening of the cervical spine could be felt and the swelling proved to be an abscess cavity (retro-pharyngeal), the bursting of which, on the patient's attempting to inspire, had almost produced suffocation. The movements of the neck were normal and free from pain, denoting absence of cervical caries. The tracheotomy tube was removed twelve hours after its insertion, the patient being able to breathe comfortably; the laryngotomy wound was dressed with cyanide gauze and the throat gargled with a weak solution of sanitas. The abscess continued to discharge pus in gradually diminishing quantities for two days, when it healed; the patient then made an uninterrupted recovery and was discharged fourteen days after admission. For some time previously to the attack the patient had occasional discharges of blood from the nose; no lesion could, however, be discovered in the nasal cavities to account for the hæmorrhage.

## Medical Societies.

### OBSTETRICAL SOCIETY OF LONDON.

THE first meeting of the session was held on Wednesday, the 5th inst., Dr. J. Watt Black, President, in the chair.

#### *Abdominal Section in Pelvic Peritonitis.*

Dr. CULLINGWORTH read a paper on the Value of Abdominal Section in certain cases of Pelvic Peritonitis, based on a personal experience of fifty cases, of which the following is an abstract:—

The question considered in the paper was whether surgical interference was or was not frequently called for in cases of pelvic peritonitis. Dr. Cullingworth replied to this question in the affirmative, and supported his opinion by a detailed record of fifty cases in which he had himself operated. The paper was accompanied by a table, showing for each case the symptoms, the physical signs, the diagnosis, the actual condition disclosed at the operation, the nature of the operation performed and the results, immediate and (where possible) remote. The cases were arranged in the order of their occurrence. The cases included the whole of Dr. Cullingworth's experience of the operation up to the end of February, 1891, and are classified as follows:—Suppurating salpingitis, 20; non-suppurating salpingitis, including six cases complicated with suppurating ovarian cyst, 12; tuberculous disease of Fallopian tubes, 2; pelvic abscess, seat undetermined, 3; pedunculated retro-peritoneal cyst, with abscesses in walls, 1; tuberculous abscess in abdominal wall, with masses in pelvis (tuberculous glands) and miliary tubercle of peritoneum, 1; hæmatocele, 2; hæmatosalpinx with hæmatocele, 3; hæmatoma of broad ligament, 1; broad ligament cysts (with ovaritis 2, with hydrosalpinx 1), 3; encysted peritonitic effusion, 1; retroflexed uterus with fibroids, 1—total, 50. He then proceeded to detail his cases. There was strong presumptive evidence of gonorrhœa in a large proportion of the cases, and in 4 cases the proof seemed complete. Nine of the cases died, a mortality of 18 per cent. Seven of the deaths were due to peritonitis, probably septic, 1 to acute nephritis, and 1 to collapse on the eleventh day. Of the fatal cases, 1 was tuberculous disease of the tubes, 2 were purulent salpingitis, 1 was double salpingitis with old hæmorrhage, 2 were suppurating tubo-ovarian cysts, 1 was retro-peritoneal suppurating cyst, 2 were old peritonitis with serous cysts of the broad ligament. As experience increased, the mortality became sensibly diminished. Hæmorrhage, to a greater or less extent, existed in 12 of the 32 cases of salpingitis. In 5 cases there was amenorrhœa, in 3 dysmenorrhœa, whilst in 12 the menstrual function was undisturbed. In 16 cases the removal of the appendages was complete, in 23 partial. Of the former

15 recovered; of the latter 17. The peritoneum was flushed in 22 cases, of which 18 recovered. Drainage was employed in 47 out of the 50 cases. In 2 cases a fecal fistula formed which in each instance healed spontaneously. In 5 cases the patients complained some time after the operation of more or less persistent pain. A sinus existed in 6 of the cases when the patients left the hospital; in 2 of these it had not healed when the patients were last seen. In 4 cases a hernia occurred in the line of incision. He pointed out that a very slight amount of swelling of the mucous membrane suffices to block the tube at its uterine end; and if pus be present in the tube it must then either remain pent-up in the tube or be poured out through the fimbriated end into the peritoneum, in either case becoming a source of danger. Salpingitis being a painless affection, the wall of a pyosalpinx may be on the point of perforation before an acute attack of peritonitis gives warning of the presence of serious disease. Suppurating tubo-ovarian cysts are usually the result of ulceration on the tubal side of the adhesion between the tube and ovary, but in exceptional cases they result from ulceration on the ovarian side. One of the chief risks in the operation for the separation and removal of inflamed tubes is the liability to mistake thickened and adherent intestine for diseased tube. The way to avoid error is to trace the tube from its uterine end outwards. The exceptional instances in which pain persists after operation for gross lesions of the uterine appendages are generally to be explained either by omental or intestinal adhesions, or by the coexistence with the actual disease of a neurotic condition, of which the pelvic pain is a mere local expression. Tubal disease in the virgin is generally, if not always, tuberculous. Hydrosalpinx, in the great majority of cases, is merely a form of retention cyst due to occlusion of the distal end of the tube from without. Simple collections of serum, both large and small, were apt to form beneath the peritoneum covering the tube and broad ligament in chronic cases of pelvic inflammation, especially in those of very long standing. Probably the best treatment of these cysts, after exposing them and making certain of the diagnosis by abdominal section, is simple puncture and evacuation, the risk of removal being, in Dr. Cullingworth's experience, out of proportion to their importance.

Dr. JOHN WILLIAMS said that he felt personally indebted to Dr. Cullingworth for bringing this paper before the Society, for although he differed widely from him both in regard to his conclusions and practice, he believed that the discussion of the paper would help to place the practice of opening the abdomen for pelvic disease on a sounder and more reasonable basis than that on which it rests at present. The first difference Dr. Williams had with Dr. Cullingworth was as to the title of the paper. He thought the title was misleading, for on examining the cases he found that 24 of the 50 were of ovarian or other cysts which were simple, inflamed or suppurating, and with regard to the propriety of the removal of these there were no two opinions. In these cases the pelvic inflammation may have been independent of the new growth, although it was well known that inflammation was a very frequent consequence of the presence of cystic disease in the pelvis. Then, again, there were 6 cases of pelvic abscess in which the only reasonable plan of treatment was to open them, let out the pus and drain them. It might be a matter of opinion whether the opening should be made from the vagina or through the abdominal wall. In some cases the way through the vagina would probably have been better, while in others the abdominal method would be preferable. There were, moreover, 10 cases of hæmatocele, one with ruptured cyst of the broad ligament and one suppurating, and one case of hæmatoma of the broad ligament. The case in which suppuration had occurred should have been treated like an abscess, but it is probable that the other nine would have got well without operative interference, for death from hæmatocele is extremely rare. He had an observation to make with regard to the result. The mortality was high, but he did not think it was higher than the mortality from these operations throughout the country generally. The cases, or many of them, presented great difficulties to the operator, and it was in such cases that the mortality was high in skilled hands. He had pointed out that skill in operating favoured a low mortality and that one great secret of a very low mortality was operating upon cases in a condition as near to that of health as possible. There was a mortality which necessarily arose from the difficulties of the operation, and this mortality was eliminated when operations of this kind were undertaken for trivial devia-

tions from health. When considering the mortality of the operation that from the disease should be borne in mind. He had seen two cases only of death from ruptured tubes or abscesses, and he calculated that with a mortality of 18 per cent. the mortality of the operation was several hundred times greater than that of the disease. Then as to the permanent result: 9 died after the operation and 1 within twelve months of cancer of the stomach, 14 were seen a year or more after the operation, 8 appeared not to have been seen. Then as to the permanent result: were the cases operated upon cured? Nine died after the operation, and 1 of cancer of the stomach twelve months after operation; this left 40 to be accounted for. Of 14 only of these was anything known after the lapse of twelve months from the date of operation; of 8 there was no account at all after they left the hospital; 3 left 32.

Mr. ALBAN DORAN considered that it was good surgery to ensure the escape of pus and the other products of inflammation, and that in so far as that object was gained Dr. Cullingworth's practice was sound. Parametric abscesses required similar treatment; it was not sufficient to make a mere puncture; a free incision should be made through an abscess which pointed anteriorly, the cavity should be washed out and then explored as carefully as the peritoneal cavity is explored in an ordinary abdominal section. Then there would be no fear of leaving a deeper collection of pus unopened. He himself treated suppurative parametritis as a matter for the operating table and not for mere puncturing and poulticing. In a recent case where the appendages and parametrium were inflamed he left the tubes and ovaries alone after free opening of abscesses. Recovery was perfect, all local signs of tubo-ovarian disease steadily disappearing. Dr. Cullingworth overlooked one cause of persistence of pain after removal of the appendages. The stump was usually more or less unhealthy, like the parts cut away, and the ligature might cause much irritation. The stump of a true ovarian tumour, it must be remembered, was usually made up of tissues free from inflammatory changes, hence it bore ligature well. When an abscess was opened without removal of appendages, then, if other parts were healthy at the time, recovery was very complete; no stump and no ligature remained behind. Mr. Doran then referred to MM. Pean and Segond's practice of vaginal hysterectomy for the cure of pelvic suppuration. British surgeons would hardly adopt that operation.

Dr. CHAMPNEYS shared in the feelings of other speakers who had objected to the title of the paper. Pelvic peritonitis was a complication of a very large number of known diseases, and he thought it was evident that a good many of these were capable of diagnosis, and had indeed been diagnosed before operation. Among these were ovarian tumours, tubo-ovarian cysts and hæmatoceles. He thought it was of some importance to point this out, because one of the chief objects of the paper was to show that abdominal section was often called for in pelvic peritonitis. In the ordinary sense of the term this was not the case, nor did the cases in the paper bear out that view. But if the title of the paper were retained, he would ask, Who in that room had ever seen 9 deaths from pelvic peritonitis, or even 4 deaths (the number of fatal cases after operation in the paper and appendix respectively)? Pelvic peritonitis was one of the commonest of all affections of the pelvis and the cases were rarely dangerous to life. As regarded the duration of the disease before the operation, he did not think that mere lapse of time proved the necessity for operation. Nothing was commoner than for patients to go about for months with this affection, or to lie up after a fashion at home. When they came under observation the temperature was raised and there was pain, both of which ceased on strict confinement to bed, and might never return after proper medical treatment. As regarded the imminence of the escape of pus noted in some cases in the paper, he did not think there was often any cause for alarm even if this took place; the pus escaped, an ordinary parametric abscess formed (often with great rapidity), and its evacuation was followed by cure. Hæmatocele very rarely justified an operation. He did not agree with the opening of pelvic abscesses by abdominal section except in rare cases. The advantage of abdominal section was the opportunity which it gave of exploring, but the risk to life was considerable; drainage was in opposition to gravitation and the risk of ventral hernia was great, for sometimes these cases necessarily required drainage for a long while. The advantage of improved antiseptics in abdominal opening was more theoretical than practical, for it was quite easy to get excel-

ient surgical results in vaginal operations if we knew how to manage them. On the whole, then, he was still unconvinced that pelvic peritonitis required abdominal section except in rare and exceptional cases.

Dr. PLAYFAIR said that none of the previous speakers seemed to him to have sufficiently recognised the great value of Dr. Cullingworth's paper. He felt that his conclusions were in many respects open to criticism, nor could he at all endorse many of them. As to the general principle that when marked structural disease of the uterine appendages existed, connected with suppuration, a free exit should be given to the pus, and that such exit was often best obtained by laparotomy, everyone nowadays would probably agree. That was consistent with sound general surgical principles. He remarked on Dr. Cullingworth's extreme partiality for the drainage-tube, which was used in 47 out of the 50 cases. In his own operations he hardly ever used it, and yet he certainly should have no fear of contrasting his results with those which Dr. Cullingworth had given. He felt quite confident that Dr. Cullingworth had resorted to drainage with an altogether needless frequency.

The discussion was adjourned to the November meeting.

The following specimens were shown:—

Dr. MCADAM ÉCOLES: Distension of Vagina and Uterus with Mucopuriform Fluid, accompanied by Dilatation of Bladder and Ureters from Pressure in a Child seven weeks old.

Dr. RUTHERFOORD: Pelvis (with Bladder, Uterus and Rectum *in situ*) of a Cat which died two hours after giving birth to five large kittens.

Dr. AMAND ROUTH: Uterus ruptured during Parturition.

## WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A MEETING was held on Oct. 7th, Mr. T. Swinford Edwards, F.R.C.S., President, in the chair.

### Presidential Address.

After alluding to the present satisfactory position of the Society, the PRESIDENT proceeded to the subject of his address—viz., urinary surgery of the present day contrasted with that of twelve years ago. The wide range of applicability of litholapaxy was first referred to, and was followed by a history of the revival of the operation of suprapubic lithotomy, the cases for which it is best suited being mentioned. The various operations upon the prostate were next discussed, including prostatotomy, as advocated by Mercier and Gouley of New York, moulding of the prostate by belled bougies, suprapubic prostatectomy as performed by McGill, and electrolysis by means of a current passed through its substance, the negative pole being inserted through the rectum. The use of the thermo-galvanic cautery as designed by Bottini was also referred to. The consideration of diseases of the bladder itself was next entered upon and the manifold and great advantages of Leiter's cystoscope as an aid to diagnosis pointed out. The advance during the past few years in the surgery of the kidney was then dealt with, the operations of nephrotomy, nephrectomy and nephrorrhaphy receiving in turn their share of attention. In relation to the surgery of the urethra the value of electric illumination for diagnostic purposes was again alluded to, the preliminary use of a 5 per cent. solution of cocaine previously to all instrumentation strongly recommended and a forcible illustration of its value as an aid to the differential diagnosis of organic and spasmodic structure was brought forward. The electrolytic treatment of certain cases of non-traumatic and resilient stricture was advocated and reference made to the diminished frequency of cases of urethral fever since the employment, both locally and by the mouth, of antiseptics. In the former relation sublimate solution (1 in 6000 to 1 in 10,000) received first preference, while boracic acid and permanganate of potash in weak solution were also recommended. For internal antiseptics salol and boracic acid were thought most advantageous, and in cases of pyuria and irritable bladder benzoate of ammonium in combination with boracic acid and buchu had been found of considerable value. Amongst the most efficacious injections for urethral discharges were permanganate of zinc ( $\frac{1}{2}$  gr. to the ounce) and the extract of Canadian pine (1 dr. to the ounce).

A hearty vote of thanks, proposed by Dr. Travers and

seconded by Mr. Lawrance, was carried by acclamation, and Mr. Swinford Edwards briefly replied.

Prior to the delivery of the presidential address the following cases were shown by Mr. KMETLEY: (1) Patient from whom he had recently removed a large cystic thyroid tumour (growth also shown); (2) young man upon whom he had operated for Undescended Testicle, bringing it down and stitching it to the scrotum; the organs on both sides were well developed and of equal size; (3) case of Sutured Olecranon-process after Compound Fracture, with resulting perfect movement.

## BRADFORD MEDICO-CHIRURGICAL SOCIETY.

TUESDAY, OCT. 4TH, 1892.

Dr. J. H. BELL, President, in the chair.

### President's Address.

THE retiring President, Mr. R. Mercer, having vacated the chair the introductory address was given by Dr. BELL, who said he had occupied that position twenty years ago, and now reviewed the changes wrought since then. These were mostly due to the intellectual activity of professional life and to the action of the General Medical Council. There was a rapidly increasing proportion of medical men to population, and the higher education of many placed them, like the clergy, out of touch with the great majority of the people; hence they were—with the masses at any rate—being supplanted by others of a lower grade. The practice of pharmacy was falling in the profession, and ere long would pass into the hands of others. With higher education amongst medical men the practice of midwifery drifted towards the midwives, who undoubtedly ought to be qualified and registered. This would probably reduce the puerperal death-rate 50 or even 60 per cent. Specialism had arisen and would develop; instead of special hospitals there ought to be special departments at general hospitals, which were cheaper, better managed and more efficient. Incurables, too, and convalescents want better looking after. In the course of twenty or thirty years these things would, he thought, be generally established.

### Exhibits.

A large number of specimens were exhibited, including histological preparations of tumours and pathogenic micro-organisms from cultures and in the tissues. One specimen of abscess of liver occurred in a man aged thirty-five, seven years after returning in good health from India; he was out of health twelve months, and when seen was wasted, jaundiced and *in extremis*. The abscess cavities contained upwards of a quart and about a pint respectively of pus.

## FORFARSHIRE MEDICAL ASSOCIATION.

### Abscess of Spleen.—Eclampsia.—Thrombosis of Basilar Artery.

A QUARTERLY meeting of the Forfarshire Medical Association was held in the anatomy class-room, University College, Dundee, on Friday, the 7th inst., at 4 P.M., Dr. Rorie, President, in the chair. There was a good attendance of members and much interest was taken in the different papers as they were read.

Dr. STALKER reported a case of Abscess of the Spleen. The patient had been seven years in the army and had had Malta fever while there and enteric fever in Egypt, but had spent the two years between the date of his discharge and the outbreak of his present illness in good health in Dundee. He came into the Dundee Infirmary after a fortnight's illness suffering from pain in the left flank, feverishness, and enlarged spleen. The fever was a continued one, latterly remittent, but with the fall of temperature there was no improvement in his general condition, and he sank after five weeks' with signs of pyemic exhaustion. A general diagnosis of enteric fever was made, but there were some puzzling symptoms throughout. At the post-mortem examination there was a large splenic abscess containing about twenty ounces of pus. There was no ulceration of the bowel.

Dr. KYNOCH then read a paper on the operative treatment of Eclampsia, in which statistics were given showing the high rate of maternal and infantile mortality in ante-partum cases of Eclampsia. This was followed by notes of a case

occurring in a primipara at the eighth month when the usual methods of treatment had no effect on the severity of the convulsions, and where recovery was much delayed on account of the rigid condition of the cervix. The various methods of treatment were discussed, and reference made to the treatment of such severe cases by deep incisions into the cervix or by Cæsarean section as advocated and successfully carried out by Halbertsma of Utrecht.

Dr. MACKIE-WHITE showed a specimen of Thrombosis of the Basilar Artery taken from a woman of seventy-three who died in the Dundee Royal Infirmary. The upper half of the artery contained clot, the outer part of which was pale and fibrous, the inner dark red and evidently recent. There was well-marked white softening of the lower two-thirds of the pons, of the anterior pyramids (superficial) and of the cerebellum in the region supplied by the right anterior inferior cerebellar artery. The duration of the illness, eight weeks, was unusual, Gowers stating that it is rare for life to be prolonged beyond a fortnight. Among the symptoms noted as characteristic were: (1) Repeated seizures affecting opposite sides of the body, the first and second with an interval of a fortnight, paralysing the right side slightly, the third and fourth on the third day before death involving the left arm and leg; (2) crossed paralysis, the right side of the face being affected along with the left side of the body; (3) conjugate deviation of the eyes to the left, while the left limbs were paralysed; (4) hyperpyrexia, temperature 108° fifty minutes before death.

#### TORQUAY MEDICAL SOCIETY.

A MEETING was held at the Torbay Hospital on July 8th, Mr. Karkeek, President, in the chair.

Several cases of interest were shown, amongst which were Primary Epithelioma of the Tonsil in a man aged sixty-three, with Secondary Enlargement of the Glands of the Neck, and a Perforating Wound of the Knee-joint treated by incision and drainage, with good recovery, by Mr. Watson, senior house surgeon, Torbay Hospital.

Dr. Wilking Stabb read notes of a case of Pernicious Anæmia which ran an unusually rapid course. The patient was a widow of fifty years of age, who had passed the menopause a year previously and had never had any serious illness. Three weeks before seeking advice she had a fall and struck her head against the kerbstone, to which she attributed her illness. She complained of debility and shortness of breath on the least exertion. She was a stout, anæmic woman. The only physical signs were a soft systolic murmur at the apex, well conducted into the axilla, and a rough systolic murmur at the base. The anæmia rapidly increased, the skin becoming waxy and the mucous membranes almost white. Slight œdema of the legs and ankles developed; also anorexia, furred tongue and much nausea, which seemed to contraindicate the administration of arsenic. Blood pale and watery; no apparent alteration in size or number of leucocytes; red corpuscles varied in colour and formed bad rouleaux. Nine days before death there was slight epistaxis, which recurred once. The disease terminated in the usual way—viz., by a severe attack of dyspnoea with shallow sighing respiration and with no sign of pulmonary affection. The attack lasted eight hours, during which time the patient lay low in bed on her left side. From the date of the fall to her decease the patient was only ill nine weeks and two days, during the first three weeks of which she was not so unwell as to seek advice. Treatment was at first by iron and digitalis; towards the close it was directed simply to relieving the digestive disturbance.

### Reviews and Notices of Books.

*Report on the Etiology and Prevention of Yellow Fever.* By GEORGE M. STERNBERG, Lieutenant-Colonel and Surgeon, U.S. Army. Washington: Government Printing Office. 1890.

In his report to the United States Government on the above subject, Dr. Sternberg has prepared a monograph on the etiology and pathology of yellow fever that should prove of very great value to those who have to deal with this fatal disease. Having carried on his investigations in Brazil, Mexico and Havana, he has had an experience that makes

the controversial part of the work much more important than it could possibly have been on any other grounds. He goes very fully into the claims put forward by Dr. Freire that he has produced a protective inoculation against yellow fever, and he maintains that Dr. Freire has not a tittle of evidence to bring forward in support of his contention that inoculated persons are less liable to the disease and that they take it in a milder form than do those uninoculated; in fact, it would appear from the statistics cited that the mortality amongst the former is even greater than amongst the latter.

In the first place Dr. Sternberg finds that the micro-organism produced as a pure culture by Dr. Freire and put forward by him as the etiological factor in yellow fever can be obtained from the skin of persons who have no trace of the disease about them; it may, in fact, be looked upon rather as a saprophytic organism than as one having anything to do with the disease. He goes very thoroughly into Dr. Freire's claims that his *cryptococcus xanthogenicus* is present in great numbers in the blood and tissues of yellow fever patients; after making a very large number of careful microscopic examinations he feels compelled to state that such organism does not occur in the body, but that it does occur with very great frequency in the skin; he believes, indeed, "that the specific infective agent in yellow fever has not yet been demonstrated," although he describes no fewer than twenty-eight forms of bacilli, eight forms of micrococci, and a torula which he has been able to separate from the blood or organs taken from cases of yellow fever; some obtained during various stages of the disease, others from the organs after they had been removed from the body and kept in antiseptic wrappings for forty-eight hours. Most of these organisms have been carefully photographed under the microscope, and in some cases photographs of colonies and drawings of the appearances of the growths in test-tubes are given, so that they may be the more readily recognised; but he failed absolutely to demonstrate the presence of any particular pathogenic micro-organism in the blood and tissues from these cases.

The organism most constantly and abundantly found was bacterium coli commune, an organism present in the intestine of healthy individuals; he considers, therefore, that its presence in the blood and tissues can have little or no etiological import. Another organism, the bacillus cadaveris, was also frequently met with. Then, too, the blood, urine and crushed liver tissue obtained from bodies recently dead were not pathogenic in the case of either rabbits or guinea-pigs, unless they were administered in considerable quantities. Dr. Sternberg found, however, that such materials preserved under antiseptic precautions for forty-eight hours were very fatal to guinea-pigs when injected subcutaneously. He looked upon the results obtained as being due to the presence of micro-organisms which continue to produce their toxins after the death of the patient. As a result of these observations, he argues that, as in the case of cholera, any specific germ if present must be in the alimentary canal, but after an extended research he has been unable to find any variety of bacillus present in any such proportion as happens in the case of cholera, for in every case he obtained a number of different species, no single one appearing to preponderate, and very few of those present liquefied the gelatine. Some of the bacilli are anaerobic, others are facultative anaerobes. One of these, which he calls his bacillus "X," he has been able to isolate from the contents of the intestine in a number of cases of yellow fever, and he holds that it may have been present in all; he has never met with it in any other conditions, and he finds that it is pathogenic in the case of rabbits when injected into the abdomen. He is, however, far from satisfied that this can be the cause of the disease, though it is the only one of all those that he has examined about which he is doubtful. From the manner in which a yellow fever epidemic extends

and from the fact that it has certain features in which it resembles cholera, he is led to believe that fecal matter is the vehicle in which the pathogenic agent passes from individual to individual, but he holds that there is no evidence that yellow fever is propagated by the contamination of drinking water, as frequently and usually occurs in the case of typhoid fever and cholera; he considers, moreover, that the organism must be a strict anaerobe.

The author lays great stress on the fact that a temporary depression of vitality is one of the most important predisposing causes in this disease, especially where the alimentary canal is affected, and, as in the case of cholera, a recent debauch is a recognised predisposing cause. "Sailors who go on shore at an infected port for a little spree very commonly turn up in the hospital, or are taken sick after they come on board ship, and serve as the starting-point of an epidemic amongst their comrades, and subsequently perhaps at the port of destination of the vessel." Finally, he says: "The experimental evidence recorded and the facts just stated seem to justify the recommendation that the dejecta of yellow fever patients should be regarded as infectious material, and such material should never be thrown into privy vaults or upon the soil until it has been completely disinfected."

The pathological part of the report, as well as the clinical and etiological, has been reprinted from the article contributed to "Wood's Handbook of the Medical Sciences." The pathological changes are evidently those associated with the excretion of poisonous products, and take the form of acute hepatitis and nephritis, characterised first of all by marked cloudy swelling, sometimes of the acute vacuolated form described by Greenfield and others, this ultimately leading in some rare cases to necrosis in patches, but usually taking the more common course of fatty degeneration. Acute interstitial changes in the above organs are also fairly well marked in certain cases. For these changes, however, we must refer our readers to the original work. Although we are naturally disappointed that no more definite results have so far been obtained, it must be confessed that Dr. Sternberg has certainly placed in a very fair light the evidence on which he has based his conclusions, and he has also given very sufficient reason for coming to the conclusion that Dr. Freire's observations and experiments are scarcely to be relied on.

*Materia Medica, Pharmacy, Pharmacology and Therapeutics.*  
By W. HALE WHITE, M.D., F.R.C.P. Lond. London: J. & A. Churchill. 1892.

THIS book contains a great deal of useful information concerning drugs, and it may at once be said that the dry details of the Pharmacopœia are reduced to insignificant proportions, while greater space has been allotted to the more interesting subjects of the action of drugs and therapeutics.

The arrangement of material does not present any novel features. After briefly defining the terms upon the title-page, the subject of pharmacy is approached and the ground is cleared by setting forth the general characteristics of alkaloids, glucosides, neutral principles and the like. Very brief notices of various pharmacopœial processes are followed by tables of weights and measures. These inevitable details lead up to a more satisfactory section, in which an account is given of the pharmacopœial preparations, which are usefully grouped according to their doses. A small oversight occurs under the heading "Glycerines," which are described as being "all liquid preparations," except glycerinum tragacanthæ, omitting reference to the glycerinum amyli, described in the Pharmacopœia as "a translucent jelly." To counterbalance this a list is inserted of non-pharmacopœial preparations, explanatory of such terms as cerata, cremora, gargarisma, nebula &c., which are often to be found in medical literature and are rarely defined in text-books. Some brief considerations connected with the prescription and with

abbreviations dispose of minor matters, and then comes an important section upon pharmacological and therapeutical actions. The author's indebtedness to those who have worked in the same branch of study is here very apparent, but his selection of material and skilful compression as a rule leave little to desire. Occasionally, as in most first editions, slight inconsistencies creep in; thus it is difficult to harmonise the statements made (p. 39 and p. 133) concerning the action of rectal injections of salt water in cases of threadworm. The greater portion of the book is made up of the pharmacopœial materia medica, only a few pages at the end being devoted to unofficial remedies which have found more or less favour. When dealing with sharply defined physiological and therapeutic actions the author has brought his material well up to date, and he writes in convincing terms devoid of enthusiastic exaggerations. It may be doubted whether much is gained from remarks like the following (p. 214): "As its action is unknown it has been given in numbers of diseases whose pathology is unknown, but without benefit." For the use of the student the value of the book is enhanced by judicious alterations of type for the more important statements.

*The Food Management of Infants and Young Children.* By G. R. SAUNDERS, B.A., M.B., B.C. Wanganui, New Zealand: A. D. Willis. 1892.

It is a pleasure to welcome this unpretentious little book, which has reached us from so far. As might be gathered from the title, it is essentially intended for the use of mothers and nurses rather than for students or members of the medical profession; hence its value lies in its lucidity and simplicity. The directions given are clear and sensible, and, although addressed to a popular audience, the author has not disdained to avail himself of the writings of many recent workers who have approached the subject from a purely scientific standpoint. The result is that in short space the author has set forth views which are fully abreast of modern teaching. He is clearly in favour of simplicity, though he gives practical rules for guidance where simplicity fails. Careful perusal of this book, which is easy to read and not overweighted with scientific detail, should go far towards helping young mothers to avoid the pitfalls incidental to inexperience and to the reckless advice of well-meaning but ignorant friends. It will also supply many useful hints for the management of the nursery and the sick room.

*On Changes in the Red Blood Corpuscles in the Pernicious Anæmia of Texas Cattle Fever.* By THEOBALD SMITH, Ph.D., M.D., of Washington.

As a result of his researches, Dr. Smith has come to the conclusion that in the anæmia that accompanies Texas cattle fever there is an exceedingly rapid diminution in the number of the red corpuscles in the blood, but it is only when the low figure of 2,000,000 is reached that what he calls embryonic or transitory forms appear. These transitory forms (macrocytes, corpuscles with granules and diffusely stained, and hæmatoblasts), however, appear very rapidly in mild cases of Texas fever and also after hæmorrhage, rising as the corpuscles diminish in number, but disappearing very rapidly after the corpuscles again begin to increase in number. In Texas fever so characteristic is this rise and fall that the presence of these transition forms "when there is suspicion of infection and no history of any very severe hæmorrhage is almost as certain a diagnostic sign as the parasite itself," and he concludes that "it is possible to estimate approximately, from the number and kinds of transition forms, the number of corpuscles still in the blood and the time which has elapsed since their destruction began. The presence of these forms is a favourable sign and may serve, when taken into consideration with the parasite, as a

fairly good basis for a prognosis." It is open to some doubt whether the forms above described are really transition forms, for recent observations on anæmia and leucocythæmia would lead us to argue that some of these corpuscles at any rate have a perfectly distinct source from that of others. It may be, however, that Dr. Smith's observations may render it necessary for us to revise our notions as to the nature of some of the peculiar corpuscular bodies met with in these conditions.

#### LIBRARY TABLE.

In the August number of the *Annales de l'Institut Pasteur* M. J. Soudakowitch continues his account of his observations on Intra-cellular Parasitism in Cancerous New Growths. He strongly combats the idea brought forward by Professor Virchow, that the parasites described by recent observers have little to do with the etiology of cancer. He still maintains that the structures he describes in the cancer cells are true parasites; that by certain features they may be distinguished from various degenerated products and altered cells; he has now been able to see falciform bodies within these parasitic cysts. He has noted the division of the body into a larger number of smaller bodies, and he has found these smaller bodies increasing in size, ultimately forming groups of the larger organisms contained in a large mass of protoplasm. In the 110 cases he has now examined he has always obtained the same results. He thinks that the young parasite passes into the substance of the cell; that there it grows slowly; that the capsule that surrounds it becomes more and more marked; that the nucleus is gradually compressed until it takes the form of a flattened layer around the capsule, to which it is closely applied; the protoplasm of the cell is also gradually distended, becomes more homogeneous, is not so brilliantly stained and ultimately may form only a thin membrane around the parasite. The parasite is then set free, its contents become divided into what may be termed "spores," and these make their way into the neighbouring cells, when the process recommences, so that a single cancer cell may give rise to the contamination of a considerable number of those cells around it. He also holds, however, that the cell containing the cancer parasite may divide and that the parasite may divide along with it, both of the resulting cells being thus infested. He does not, however, seem to take into account that these parasites as they grow must give off effete matter, which probably may have a most important influence in determining the proliferation of the epithelial cells in the immediate neighbourhood, and that therefore it is not to be expected that one of these parasites would be found in every cancer cell. These and other recent observations on cancer open up a new line of research, and one that promises to give us some new light on the etiology of this fell disease.

THE *Veterinarian* for September opens with the first part of an interesting paper by Mr. Fred. Smith, M.R.C.V.S., F.I.C., on Veterinary Hygiene, which was read in Section III. of the International Congress of Hygiene and Demography. There is a report of the Government Veterinary Surgeon of Queensland on experiments made with a view to test the various specifics in use for expelling parasitic worms from sheep; solutions of arsenic, turpentine mixture, Hayward's mixture, cocoa-nut oil, powder supplied by Dr. Thos. L. Bancroft, and salt and lime, were used, and as the outcome of two sets of experiments, it is considered that the preparation of arsenic has given the best results. Sheep take it readily. "It is recommended that three doses should be given at intervals of nine days between each dose, the sheep to be kept without food for at least twelve hours before a dose and for two hours after; they may be allowed water half an hour after receiving the medicine." The remainder of the journal is taken up with accounts of the meetings of the Royal Agricultural Society of England, the Royal College of Veterinary

Surgeons, Royal Veterinary College, Central Veterinary Medical Society (at which there was a discussion on intestinal obstruction in the horse), and the Scottish Metropolitan Veterinary Medical Society.

The *Journal of Anatomy and Physiology*. Conducted by Sir GEORGE M. HUMPHRY, Sir WILLIAM TURNER, and J. M'KENDBRICK, F.R.S. Vol. XXVI. Part 3. April, 1892. London: Williams and Norgate.—This part contains no less than eighteen separate papers, with an account of the proceedings of the Anatomical Society of Great Britain and Ireland. The more important of the papers are: 1. The Myology of the Larynx, by A. A. Kanthack, with two plates; a paper of much importance to laryngologists. 2. A Note, with a good bibliography, on Identical Malformation in Twins, by Bertram Windle, D.Sc. 3. On the Cause of the Twisting of the Umbilical Cord, illustrated by mechanical models, by F. J. Allen, M.A. 4. The Nutritive Importance of the Yolk Sac, by Arthur Robinson, M.D.; the Comparative Anatomy of the Muscles and Nerves of the Limbs of Anthropoid Apes, by David Hepburn, part 2, with a plate. 5. The Cerebral Hemispheres of the Ornithorhynchus, by Sir William Turner. 6. A Few Applications of a Physical Theorem to Membranes in the Human Body in a State of Tension. 7. On the Effect of certain Drugs on the Reflex Excitability of the Spinal Cord, by William Stirling, M.D. 8. On the Pedal Skeleton of the Dorking Fowl, by G. B. Howes. 9. On the Enzymes produced by Bacteria, by F. Allan MacFadyen, M.D.

*Eisenbahn-Verletzungen in Jarenischer und Klinische Bergichung.* Von HERBERT W. PAGE, M.A., M.C. Cantab.; F.R.C.S. Eng.; Chirurg am St. Mary's Hospital &c.; Autorisirte Deutsche Uebersetzung von Dr. S. PLACZEK, Arzt in Berlin. Berlin, 1892.—We congratulate Mr. Page on the appearance of this German translation of his excellent little monograph on the subject to which he is known to have given great attention and on which his opinions are of great value.

## New Inventions.

### URINE CHARTS.

WE have before us two useful additions to the clinical armamentarium, for the purpose of accurately and fully recording the details of the qualitative and quantitative estimation of the urine. To Mr. Manley Sims we owe a volume of these charts drawn upon a simple plan, but containing ample space for the record of the chemical and microscopical characters of the sample of urine examined. The value of such charts is twofold: it saves time to the practitioner in making his notes, and ensures that his examinations shall be systematic and thorough. On each page the outline of the report appears in duplicate, which not only serves the purpose of making a double entry, but also furnishes an ample supply of records within the compass of one volume. The other series is issued by the well-known medical publisher, Mr. H. K. Lewis, of Gower-street. Here each chart is on a separate sheet, and contains several more items than the preceding, under the headings of "normal" and "abnormal" constituents respectively, although, by the way, the first five subjects (quantity, colour, specific gravity, &c.) should not have been classed as "normal constituents." There is some utility also in the memoranda of the normal characters which are appended to each column. We commend these publications to the notice of practitioners and hospital officers, who will find them very serviceable and convenient.

### THE HAMMOCK LEG-REST.

THIS leg-rest is patented by Mr. William Carter of Masham, Yorkshire, and like many useful inventions is extremely

simple in its construction. It consists of a foot piece, two side supports, which fasten to it, one on each side, and a bag made of canvas extending across between these, making a kind of sling or hammock for the limb. It is very comfortable, can be raised or lowered, and can be got ready for use or taken to pieces in about forty seconds, the support for the

leg forming a bag in which the whole can be placed and readily packed in a portmanteau or carried in the hand. It will prove a boon to those who from one cause or another are compelled to resort frequently to the use of such aids. Its simplicity, compactness and utility will recommend it.

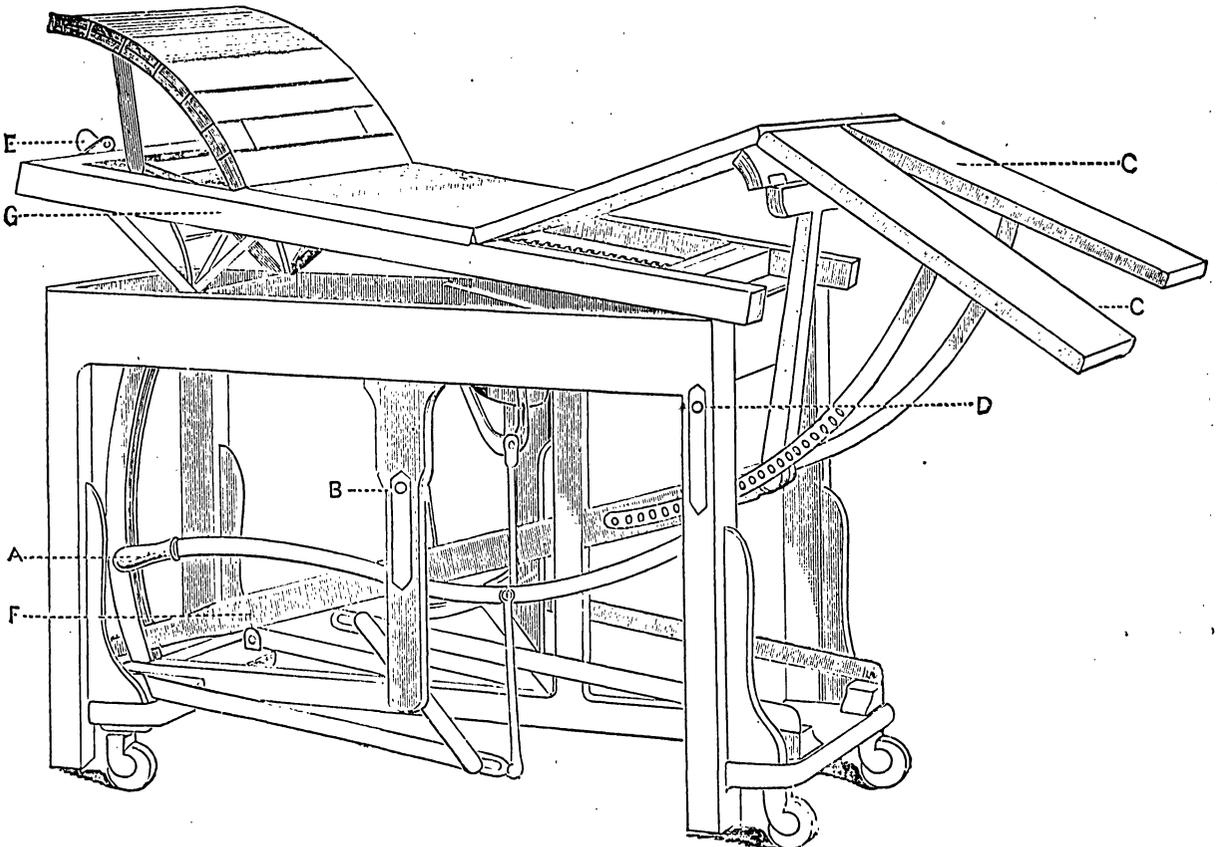

**IMPROVED OPERATING TABLE.**

This table, which has been in use for some years at King's College Hospital, was designed by Professor William Rose to meet a suggestion of Miss Monk, the sister-matron, that an operating table capable of being moved to the bedside would

be a great desideratum and saving of suffering in many cases where the frequent moving of a patient is attended with pain. Several of these have now been made and are in use in many of the London and provincial hospitals, and also abroad. The principal advantages of this table are that by a simple mechanical contrivance four rubber-tired wheels are brought into play and the table moved smoothly and silently about on them, whilst by reversing the action it can be made absolutely steady on its legs. The head-piece is jointed on the same principle as a revolving shutter, and is raised or lowered by means of a handle, so that the patient's head can be elevated or depressed at pleasure. These and other movements are indicated by the letters on the engraving, made from a photograph of the table. At King's College and other hospitals the tables are worked in duplicate, so that whilst one patient is being removed to the ward another can be at once brought into the theatre, having been previously anaesthetised, if desired, in an adjoining room, and thus much time is saved.

A. Handle for raising or depressing the rubber wheels, released by touching the button B. To place the table on wheels, depress this handle; to put the table on its legs, press the button and raise the handle. C. Leg-pieces which can be raised or lowered at pleasure, or detached entirely at the hinge. To lower them, press the side button D. E. Handle attached to revolving screw to raise or lower the jointed head-piece. F. Long lever to raise or depress the lower third of the table top. The lever as shown in the engraving is depressed to its full extent, but may be maintained in any position by a spring catch in the handle. G. Top frame of table, hinged at the lower end to the main frame, to allow of raising the upper on iron supports (not often required). Arm-pieces may be added to this top frame, but, for clearness of view, are omitted from the engraving.

The table is made by Mr. Roskilly of 7, Berkeley-road, Regent's Park, N.W.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 15, 1892.

EVEN those investigators who maintain that many physiological problems can only be solved by means of experiments on living animals—experiments controlled by law and held in check by careful inspection—cannot but feel much commiseration and perhaps a trace of contempt for the pitiful arguments that were advanced by the champions of “antivivisection” last week at the meeting of the Church Congress at Folkestone. It is a curious fact that, although in many respects we retain some of the instincts of the savage, notably our love for hunting, fishing and shooting, we as a race are greater lovers of animals than any other people on the face of the earth. Nowhere is such a tenderness for, and carefulness of, the interests of the lower animals so strongly manifested, especially in regard to those animals with which we come in contact in our daily life. The sportsman who unthinkingly maims a bird which may live in pain for days afterwards will treat his dog or his horse as a friend and companion. So the medical man, being human, does not for a moment object to experiments on animals being controlled by well-defined regulations, which are already of such a character that the possibility of cruelty or unnecessary pain being inflicted on any animal may be said to be reduced to a minimum. These regulations are no doubt the outcome of the innate horror that we as a nation have of inflicting unnecessary suffering on man or beast. Taking up this position, we are satisfied that although the discussion may have opened the eyes of many infatuated and, let us charitably suppose, ignorant people, we cannot help thinking that even so intelligent and highly educated a body as that drawn together at the meeting of the Church Congress at Folkestone was not the proper court of appeal in regard to this matter, and even those who raised the question must now feel that they laid themselves open to the well-deserved reprimand which they received from the thoroughly conscientious men who took up the cudgels in defence of so-called “vivisection” as practised in this country. Bishop MOORHOUSE and Bishop BARRY have raised their own standards of morals and formulated their individual codes of ethics. As far as Bishop BARRY is concerned we have little or no information as to the basis of his code, except from what appears on the face of his paper. Bishop MOORHOUSE, however, leaves us in less doubt on the matter, for, as a contemporary points out, his code of ethics appears to be based on the necessity that his voice should be preserved to him. He assures us that “for himself he would abstain from animal food if anyone would show him how he would live without it and keep his voice.” We assume, of course, that the Bishop of MANCHESTER has consulted those best qualified to inform him on a matter of such importance—viz., those who have made the study of the body and its functions a special life-work. We must suppose, therefore, that he is quite willing to accept the opinion of the medical profession on a subject of vital personal and ecclesiastical importance. If, then, Bishop

MOORHOUSE is not guided by his own standard of morality and ethics in this, why does he appeal to the Church Congress to support him and his ethics against the medical profession in a matter of which they have also made a life-study—physiological and pathological questions, some of which, they say, can only be settled by having recourse to experiments on animals? Let the members of the Antivivisection Society place themselves in Bishop MOORHOUSE'S position as regards the ethics and morality of the question—and we cannot allow that a bishop has any right to speak except as a theologian and as one who has studied ethics and morality, and who claims to have a higher information than ordinary mortals on those points (so high, indeed, that Bishop DOWDEN says that his morality is “morality up in a balloon”)—and where will they be landed? How many vegetarians are there in the Antivivisection Society? Vegetarians have the courage of their opinions, and provided that they do not take animal life in any form, we say that they are thoroughly conscientious and honourable, though we hold that they are arguing from wrong premisses. How many are there who will not drive a mutilated horse, who will never eat a bled calf, a fattened hog, a stuffed capon or a *pâté de foie gras*? How many of them can conscientiously say that, although they have shootings, they have never been cruel to bird or rabbit or that they have killed every bird they have shot at and have left none in the fields to linger in agony and die from exposure or starvation? Who of them can say that they have never set or caused to be set traps and snares for animals, which when caught have been held by broken limbs? Such things are countenanced by many of those who are open-mouthed in their proclamation of the cruelty of experimenting on animals. We do not intend to criticise the actions or the motives of those who do these things, but we contend that so-called “vivisection” as practised at present, and as we hope it may long be practised under careful limitations and vigilant supervision, does not in one year, to put it mildly, cause one-hundredth part of the suffering that is inflicted on animals in a single day in other ways. Most of the men who perform experiments upon animals would not inflict unnecessary suffering on the meanest of GOD'S creatures; they are not guided by motives of cruelty or even of a desire to obtain pleasure, wealth or health for themselves; they are working to obtain methods by which they can prevent the spread of disease or by which they can alleviate suffering when disease has attacked their patients, be they human or animal. Anæsthetics are used in all cases where anything beyond the slightest discomfort is anticipated, and every effort is made to alleviate and to minimise suffering in the animals experimented on.

Is it not better, then, to gain a preliminary knowledge on physiological subjects even at the expense of the lives and of some slight suffering of a few animals than that experiments should be made on man? There are certain members of our profession who, doubtless from conscientious motives, maintain that no experiments should be made on animals; but, fortunately for patients, such men are comparatively few in number. There are people who, whilst receiving all the benefits that the medical profession can give (whether these benefits be the result of experiments on animals or not), are willing to join in a popular

cry and to contribute means for the advancement of its propaganda. This particular agitation, though it may have many earnest and conscientious advocates, is dependent, for the most part at least, on misrepresentation of facts, on the ignorance of credulous and simple people, or it may be on the desire for advertisement which is strong in the minds of many men who are not always too scrupulous as to the special manner in which such advertisement is obtained, and who, if "vivisection" were abolished to-morrow, would find some other means of obtaining that advertisement and public prominence. We believe that such persons are few in number, but that their influence is great we have ample evidence in the fact that so many people, utterly ignorant of the whole question, are induced to come forward with their personal support and monetary contribution to carry on an agitation which is now kept alive only by artificial stimulation.

This question having been raised at the Church Congress, we feel bound to leave no room for doubt as to the opinion we hold on this question. Let us at once say that we respect those who consider, that under no circumstances should animals be mutilated or slaughtered for the benefit of mankind; they are perfectly consistent, and we should listen to every argument which they can advance in favour of their theses, although none that have yet been advanced by them have been sufficiently strong to convince us that theirs is the right position.

The whole question of "vivisection" may be put in a nutshell. Does the end justify the means? We maintain that this question can only be answered by those who have a knowledge of the results already obtained and of the work that still requires to be done. Bishop MOORHOUSE has learned what is good for the preservation of his own voice, a voice that is often raised in the interests of justice and truth (though in this instance we believe it is used in the advocacy of error); that is a matter in which he is personally concerned and in which his experience has helped him to form an opinion. Having made up his mind that he may do evil that good may come in this matter, he must leave it to the physician, who from sad experience knows only too well how much is still required to be done in the interests of suffering humanity, to determine whether the end of alleviating suffering in man and many animals justifies the means of experiments on a comparatively few animals.

---

No trustworthy account has yet been written of the results of the International Sanitary Congress which met at Venice in January last, and which it was necessary to supplement by a gathering in May. The object which was in view was practically the same as that with which the conference at Rome in 1885 endeavoured to deal—namely, to determine what restrictions it was desirable to impose on the passage of ships through the Suez Canal in order to prevent the importation of cholera into Europe. No international agreement was arrived at in Rome because, whilst a large majority who followed the lead of France demanded a stringent quarantine, both as regards sick and healthy, on so-called infected vessels, and this for a recurring period of five days, the English delegates maintained that since cholera had never spread to the Continent by means of arrivals from England, English ships ought to be allowed to

proceed to English ports without being subject to any other restriction than that they should communicate with no other port or territory on the way, whether the shores of the Suez Canal or those of the Mediterranean were concerned. The delegates of Great Britain were completely defeated in so far as numbers were concerned, but their opposition led to the entire defeat of the Conference, which adjourned, never again to assemble.

The meeting at Venice was, in certain respects, similar to the one at Rome. At the request of the Austrian Government Great Britain entered into an arrangement as to the conditions which should guide the two countries at the Conference, and an Anglo-Austrian protocol was signed accordingly. The terms of it need no discussion here, for, as at Rome, the English proposals were opposed by France; the French delegates again carried a great majority of their colleagues with them, and having done this they presented a counter proposal. This counter proposal professed to meet the views of England as far as it was possible to do so, but from the *procès-verbaux* now published, it is evident that the international agreement arrived at by the majority assembled at Venice was not assented to by this country, for the names of the British delegates are conspicuous by their absence in the convention which was signed. But, for all this, the Venice scheme presented certain great advances on anything that Europe had hitherto been willing to agree to; and even as regards English shipping, there can be but little doubt that if the scheme had been fairly worked the advantages to this country would have been considerable, especially if we compare its regulations with that which might have been enforced under the then regulations of the Alexandria Board. Indeed, the gathering at Venice will always be remembered by reason of the fact that the nations concerned consented for the first time to abandon the old practice of judging a vessel to be infected because she had come from an infected port, and decided that she was to be held infected or not according as she had had cholera on board or not. Mr. J. W. LOWTHER and Dr. MACKIE represented this country on the occasion, and they point out that had these amended regulations been in force during a term of years preceding their enactment hardly any vessels would have been subject to restrictions and detention on the ground that they were infected, whilst the minor restrictions attaching to suspected vessels would have been but trivial.

But from a Blue-book published by the Foreign Office, a volume which contains such of the papers relating to the Venice Conference as were laid before the two Houses of Parliament, it would appear that during the sittings at Venice the conclusions which were being arrived at were submitted to the Local Government Board and commented on by the medical department. Thus, in January Dr. THORNE THORNE points out that whilst the French proposals embody great concessions they also contain objectionable features of considerable importance—e.g., for infected vessels a five days' detention was prescribed, as at Rome, this period to be repeated every time some local officer chose to hold that a fresh case or a suspected one had arisen among those detained. Dr. THORNE THORNE further objected to the detention of healthy people in Egyptian or Arabian lazarets, as being calculated to spread rather than to prevent cholera; he reminds the Government that the system proposed was mis-

called "isolation," being in fact the "quarantane de rigueur" of the Constantinople Conference of 1866; and he arrives at the conclusion that many of the regulations proposed at Venice were not only unnecessary but calculated to involve danger to those who might be subjected to them. Shortly after these comments were made the delegates were informed in a despatch from LORD SALISBURY that, in his opinion, the Conference had better adjourn. The adjournment then took place, but before parting Europe *minus* England signed a convention which is embodied in the Blue-book.

Then came an interval, during which certain communications passed between the Foreign Office on the one hand and the French and Austrian Governments on the other, the outcome of which was that on May 17th the Marquis of SALISBURY, in an admirably drawn up code of instructions, deputed DR. THORNE THORNE and Mr. PHIPPS of H.M. Embassy in Paris to meet French and Austrian delegates in the French capital, for the consideration of a number of points upon which Her Majesty's Government had been unable to agree with the other European powers assembled at Venice; and the result was that on June 9th a fresh convention was signed in Paris by the delegates of the three Governments there assembled. This new convention has been accepted by the other Powers, and it therefore contains the regulations which now control the passage of the Suez Canal in so far as the prevention of cholera is concerned. These regulations, which are set out in detail in the published documents, may be briefly summarised as follows:—

Suspected ships, that is to say, ships having had cholera on board, but in which no fresh case has arisen within seven days, may pass the canal at once "in quarantine"—that is to say, without touching either shore—provided they carry a doctor and a steam disinfector on board, and that the needed measures of precaution have been taken on the ship. If without doctor or stove the ship may be detained for disinfecting and other purposes for twenty-four hours.

Infected ships constituted the class of vessels as to which the second conference at Paris was mainly held. They too are divided into two classes, according as they have, or have not, on board a doctor and a proper disinfecting stove, and they are all vessels which have had a case of cholera on board within seven days before arrival at Suez. Those without doctor and stove have to submit to medical judgment at Suez; any cholera sick must be placed in hospital, and the remainder of those on board, who in such cases will be nearly always members of the crew only, may be detained under observation for a period varying under a sliding scale from two to five days, during which time disinfection will be carried out. Vessels with a doctor and means of disinfection—that is, passenger and troop ships—are otherwise dealt with. Only the actual cholera patients need be landed, and the vessel may be detained for twenty-four hours for disinfection, which may be carried out on board, and which is limited to the part of the ship and the articles which the doctor on board decides to have been subject to risk of infection. As regards others on board, only "suspects" can be interfered with, and no one is to be regarded as suspect unless the doctor on board declares him to have been in direct contact with an infected person or with infected

things. Such persons may be detained, either on the ship or on a float to be provided, for a period varying under a sliding scale from twenty-four hours to five days, according as the last case of cholera occurred on the day of arrival or from five to seven days before arrival at Suez. After disinfection, which must be performed in twenty-four hours at the most, the vessel, if she chooses to leave her "suspects" behind, can at once pass through the Suez Canal in quarantine, and so proceed to any European port. The differences between the Venice Convention of Jan. 30th, 1892, and the Paris Convention of June 9th, 1892, are set out in parallel columns by DR. THORNE THORNE; and in submitting the table he points out that, according to data supplied by Mr. LOWTHER and DR. MACKIE, only two out of a total of 16,491 vessels would during the preceding five years have come within any of the restrictions as to infected vessels, and that according to information supplied by the chairman of the Alexandria Board the detention of these two vessels for disinfecting purposes, and of those persons who would have been regarded as "suspects," could not have exceeded a period of from twenty-four to forty-eight hours, and that even this period might have been further reduced at the option of the local authority.

The conclusions come to are based on sound medical data. The differentiation of vessels according as they carry on board a properly qualified medical adviser and adequate means of disinfection is a reasonable one; and it must be a satisfaction to this country, under whose flag 80 per cent. of the traffic passing through the Canal now sails, that a practical and scientific solution of this question has, after so many years, been arrived at. We would add that no one conversant with the history of the subject will fail to see that the French delegates must have approached their English *confrères* in a conciliatory spirit, and with an evident desire to meet British views as far as they could without alienating their less progressive colleagues representing other European States.

WESTMINSTER ABBEY in England, Montmartre, preliminary to the Panthéon, in France, have within a few days of each other received the mortal remains of ALFRED TENNYSON and ERNEST RENAN. It will be long before either resting-place admits a nobler guest. Humanists, both of them, in the highest sense of the word, they both had at heart the good of their fellow man, and gave to the end they had in common the best of their mental lives. It is not for us to bring either of them to the crux of religious orthodoxy or to appraise the ultimate value of their work. But that each in his own way sought to guide humanity to "an ampler ether, a diviner air" can be denied by no one familiar with what they wrote. In RENAN the analytic genius—in TENNYSON the sympathetic—was predominant. The former strove to purify all that was most precious in the bequest of the past and to bring it into harmony with the moral energy of the present. If he destroyed, it was to rehabilitate, if not to rebuild. It was not to make the world poorer that he consigned so much of what it cherished to oblivion. The losses he inflicted he held to be really gains, as lightening the wings of thought for yet higher flights and for the attainment of a loftier ideal. In one of his later writings he says, "J'ai tout critiqué, et, quoi qu'on en dise,

j'ai tout maintenu"; and in the same spirit he concludes, "Justice will reign, and the virtuous man will find at the end of all things that he has been the best inspired." What is this but another version of TENNYSON'S belief that "Good shall be the final goal of ill"?—a belief arrived at not by the seemingly iconoclastic methods of RENAN but by the sympathetic contemplation of the Creator as revealed in His works, by the poet's gift of divining and realising the cosmic harmony.

As in the case of all great thinkers and teachers there was an undertone of melancholy in their most characteristic utterances. The solemn admonition of the Roman satirist—

"Tecum habita; noris quam sit tibi curta supellex,"

was ever present to both. The pride of knowledge, degenerating so often into the "glorious certainty" of the sciolist, belonged to neither of them, and to the close of life they were students in fields distant from their own. RENAN, in a memorable passage, regrets the incompleteness of the purely literary or humanistic training, and desiderated in his own education a larger infusion of nature-study and of exact science. What was so bitterly felt by the teachers of the Roman Empire, that its youth were made artificially stupid "because they neither heard nor saw anything of the world with which they were in daily contact," but were nursed *sententiarum vanissimo strepitu*, was also recognised by RENAN. A happier system of education was TENNYSON'S portion; but even that he was at pains to supplement by the nature-study which reacted so healthfully on his genius and which gives so enduring a charm to much of its expression. His poems, from the earliest to the latest, teem with evidences of minute and exact observation of all life, animal or vegetable, however lowly; and the sentiment of nature thus fed and fostered preserved his genius from not a little that, under less wholesome influences, would have been unsound, not to say morbid, in speculation and practice. But the sense of the *curta supellex*, the "slender furnishing" which is all that the best instructed can attain to, he was never without; and to the last we see traces in him of the student, patiently perfecting himself on sides where he felt himself weak, and evoking latent or undeveloped capacities by what BACON has so beautifully called "the georgics of the mind."

But in the intellectual humility which impelled a RENAN and a TENNYSON never to rest satisfied with proficiency in their own *métier*, but wistfully to contemplate and even patiently to cultivate fields of knowledge from which they had been wholly or partially excluded, is there nothing for the nature-student or the man of science to take to heart? No *littérateur* could be more accomplished in his department than RENAN in French prose or TENNYSON in English verse; the former in the translucent clearness and the liquid curves of his periods, the latter in the felicity of his phrase and in the flow and cadence of his rhythm. But how few the writers who share a kindred sense of deficiency and who nobly strive to retrieve it like the master humanists of France and England. In times like these, when education is so tempted to spurn all but the "learning that pays," when the text-books of the crammer have reached the perfection of arms of precision, enabling those proficient in them to score effectively at the examining board, with the least possible expenditure of individual

thought, is it really opportune for men of science to disparage humanistic culture, to vote a decent burial for the classics, and to concentrate the student's work more and more on what simply appeals to his observation? Is it quite in keeping with the character and claims of a liberal profession to limit the range of study so as to exclude the subjects most conducive to disciplining the imagination, refining the taste and enlarging the sympathies? Such has not been either the precept or the practice of the masters of professional skill in times past. Rather would they have sided with the great leaders of humanity, such as those just lost to us, in rejecting no culture which could make the mind a more powerful and more delicate instrument, whatever the field of its exercise, but in welcoming all learning which enlightens, ennobles and refines, especially if its subject be man himself, whether in health or in disease.

WE have received from Dr. LESLIE PHILLIPS, one of the Hon. Secretaries of the Medical Defence Union, a letter on the subject of medical aid associations, which he has addressed to the General Medical Council. It is too long for insertion in our columns, but we may here give the drift of it. The subject is not a new one. We have often submitted to the notice of our readers illustrations of the working of these associations, especially in regard to the matter of their illiberal treatment of medical officers. What is now in Dr. PHILLIPS'S letter is the detail in which he gives similar illustrations and the clearness with which he argues against the fundamental principles involved in the relation of the medical man to the association. Such associations are a new invention and one by no means creditable to the working classes, who are not destitute of liberal and grateful feelings to the medical profession, or would not be so if ill-conceived forms of medical charity and pauperism did not lead them to underrate the value of medical service. The old-fashioned club and the more modern form of it, the provident dispensary, both aimed at securing the attendance of medical men for their members on easy terms; at any rate the money paid went to the medical officer, or all that was left of it after paying essentially medical expenses. But in this new-fangled institution—the "medical aid association," the medical man not only does all the medical work, but he receives a very scanty allowance for doing it, and the rest of the money paid (ostensibly for medical service) is put coolly to the credit of the association, to accumulate and to be invested in the shape of property, or to be distributed as dividends among the members. The medical officer is made not only to do medical duty, but to make money for those whom he so serves. In other words, the medical aid association is a "business" the work of which has to be done, and *can only be done*, by the medical officer, but the profits go to the association, *alias* the company. The members of this association are thus profitably interested in medical practice. Dr. PHILLIPS holds that they carry on medical practice under "cover" of their medical officer, and there is much to be said for this way of putting it. A few of the concrete instances which he gives will best enable our readers to understand his meaning. The particulars given are in no sense private, being extracts from the annual reports of the different medical aid associations.

Northampton Friendly Societies' Medical Institute receives

an income of £49 3s. 6d. from rent of property and assembly rooms, and among its assets is stated freehold property, £2718 3s. 3d.

*Lincoln United Friendly Societies' Dispensary* possesses freehold property and other assets valued at £1006.

*Bristol Foresters' Medical Institute* reports: "Our income has exceeded our expenditure by the sum of £116 5s. 7d., thus showing a very handsome profit. . . . Pay off the mortgage of £250 upon the building was successfully carried out. Thus in four years after the purchase of the large and commodious premises for the purpose of carrying on the work of the institute the building has been entirely freed from any liability." Present value of the estate, £1087. The committee, secretary &c. received fees of about £50.

*Derby Medical Association* presents a purse of £20 to a gentleman, together with a portrait of himself executed in first-rate style, and reports:—"At the commencement of the year we were enabled out of the surplus profits to declare a dividend at the rate of 3s. 6d. in the £ on the amount of levies paid for the year 1891, which absorbed the sum of about £210." Secretaries, treasurer and committee over £87 18s. 0d., the credit balance of capital account standing at £1942 14s. 8d.

*Kidderminster Medical Aid Association* has paid off the whole of a mortgage of a property owned by the Association.

*Wolverhampton Medical Association* permits a surgeon to attend midwifery cases, but his industry is taxed to the extent of 5s. a case for the benefit of the Association. In other societies, such as Nottingham, the *whole fee* belongs to and is paid to the society. In this (Wolverhampton) Association a former medical officer, Dr. —, received £250 a year; at the end of his fifth year of service he asked for an increase of salary. This was refused, although the income of the Association was £1835, and large profits were hypothecated to the acquisition of various assets—e.g., £550 worth of land. The second surgeon obtained £150, rising to £175 a year. Here we have a medical aid association carrying on, in their own words, "an increasing business," receiving an income of £1835, derived solely from medical fees, of which only £498 is paid to the surgeons, the rest being profits accruing to the Association and used for carrying on its business and increasing its wealth.

*Preston Medical Association* reports: "The mortgage on our new premises has been reduced by £250, leaving us now only £340 in debt, which, at our present rate of progress, will not be long before it is cleared off altogether." No doubt, for we read in the balance sheet: "to amount received from private practice, £369 3s. 9d.," against which is placed 'Dr. —'s share of private practice, £173 2s. 11½d." (!)

There can be little difference of opinion in the profession as to the nature of this kind of "medical business." It is undignified as respects the medical man. He demeans medical service by giving it for a paltry remuneration, not only to the working classes, many of whom get better wages as mechanics than he will get for attending thousands of patients, but to tradesmen and all and sundry that are encouraged and invited by every device of publicity and advertisement into this huge net. For not only does it tend to swallow up all the clubs and provident dispensaries of a neighbourhood, but to include, without inquiry as to fitness, the well-to-do patients of other medical men. The medical man not only sells his skill to his actual patient on low terms, but agrees to give part of his obstetric fees, or all of them, as in the case of the Nottingham Medical Association, to the Society. Can anything be more unrighteous, not to say mean, than that a medical association with an increasing business, receiving £1835, as in the case of

the Wolverhampton Association, should refuse to give, even at the end of five years, more than £250 a year to its chief officer? That a medical man should make himself the agent of such a "business" is an undignified and an indefensible position; and we challenge the gentlemen holding these posts—many of them we believe uncomfortably—to deny this. Dr. PHILLIPS intends to try to carry the matter a step further and to have the matter brought before the General Medical Council. The offence has not yet been recognised or defined by the Council—that is, the offence of enabling a medical aid association to make money by the medical practice of its medical officer. According to the present views of the General Medical Council, "covering" consists in the countenance or sanction given to an unqualified practitioner by a registered practitioner. The question raised by Dr. PHILLIPS occurred in a case that came before the Medical Council at its last meeting, where the medical officer of a medical aid association was charged first with employing an unqualified assistant, and secondly with enabling a trading company—an association of mechanics and tradesmen—to make money by employing a medical practitioner as their servant. The Medical Council considered the first charge not proved. In regard to the second, the President said, "They did not deal with that; it was not their business." If such a question is to be again raised in the General Medical Council it is important to consider whether it should be raised in the shape of an abstract resolution for the guidance of gentlemen many of whom would not willingly do what the Council disapproved, or in connexion with an actual case. It would be more satisfactory if such a question could be settled by the general action of the profession and the public spirit of its individual members. The counsel for the gentleman charged in the case to which we have alluded argued that before the Council could condemn a practitioner for entering into the service of such an association it should define and proclaim the offence. There is much to be said for this. But, as we have suggested, it would be more satisfactory if this evil could be corrected without the intervention of the General Medical Council. We notice one point more. Dr. PHILLIPS writes his letter to the Council in his own name, but he is one of the Honorary Secretaries of the Medical Defence Union. He should have made it clear whether he writes on his own account or in his representative capacity.

## Annotations.

"No quid nimis."

---

### THE INTERNATIONAL MEDICAL CONGRESS OF 1893.

FROM Rome, under date the 10th inst., an Italian correspondent writes:—"The preliminary arrangements for the great triennial parliament of the profession proceed to the entire satisfaction of the Central Committee. Much gratification is felt at the daily increasing number of the adherents and at the cordiality of tone with which they are conveyed, while the representation of scientific bodies, not only in Italy but throughout the world, will surpass in numbers and distinction that of any antecedent congress of the kind. From America, North and South; from the United States and the Argentine Republic; from Great Britain

and her colonies; from Germany, Austria-Hungary, Denmark, Spain and Portugal, have already been received intimations to the effect that in each of these States or dependencies will be formed a committee to coöperate with the central organising committee in Rome, so as to obtain as representative a body of the profession—consultants, practitioners and lecturers—as the respective nationalities or communities can yield. Another important step in view of the approaching Congress has also been taken. The directors of the various continental lines of railway have been addressed by the organising committee with the object of making travel not only to and from but also within the peninsula as convenient as possible. Many of those taking part in the proceedings will be loth to leave Italy without availing themselves of a probably unique opportunity of seeing the treasures, archæological and artistic, to say nothing of the natural beauties, of a country renowned in history and song. For the benefit of all such the organising committee are in treaty with the railway and steamboat companies and the municipalities of the Italian kingdom for the chief conduct and comfortable accommodation of visitors to the principal centres of interest so as to ensure their enjoyment of the same as expeditiously and satisfactorily as may be. The organising committee, indeed, have already received from the Austrian Lloyd's Steam Navigation Company a spontaneous offer to reduce its fares by 30 per cent., while one tourist agency, well known in Europe, is preparing a series of special trips, for which the coöperation of the Italian railway and steamboat services is in course of being engaged. With each successive international medical congress the facilities and advantages placed at the disposal of its members seem to be multiplied and perfected, and that which meets in Rome in the last week of September, 1893, will, it is evident, mark a distinct advance in these respects on the most brilliant of its predecessors."

#### THE METROPOLITAN ASYLUMS BOARD AND ITS CRITICS.

A VERY sharp passage of arms is taking place in *The Times* between Mr. Littler, Q.C., chairman of the Middlesex County Council, and a member of the Metropolitan Asylums Board. Mr. Littler attacks the management of the Board and the way in which they invade pleasant districts of London, or rather of the county of Middlesex, for the purposes of the inhabitants of London. The latest offence is the erection of a hospital at Tottenham—for the present temporary—for the reception of scarlet fever cases. Mr. Littler describes with eloquence and with something of special pleading the grievance of residents and owners of property in a pleasant suburb who wake up one morning and find that their villas are to be confronted with a fever hospital. He suggests that the Asylums Board should be swept away altogether, and each district be required to provide accommodation for its own infectious cases. This is a very natural suggestion, but it is not so practicable as it is natural. Even if the forty local authorities could all be got to do their duty, and if they could obtain convenient sites, the expense of such a course would probably be greater than the present, great as that is. Then, as the Asylums Board Manager says in Wednesday's *Times*, it has not yet been shown that scarlet fever or diphtheria spreads unduly in the neighbourhood of hospitals for the reception of cases of those diseases, as has been proved in the case of small-pox. The question is a serious one. We cannot help thinking that a demoralising facility for going into the hospitals has been fostered, until those are tempted to use them who could isolate cases at home, to the grievous burden of the ratepayers. We agree with the Asylums Board Manager that it is not seemly to have the representatives of public bodies arguing with each other in the public press. The development of the hospitals for infectious cases has been carried already beyond the number contemplated by

the Royal Commission. The proper course, it seems to us, would be to appoint a Commission to inquire into the working of the present system, its effect in restricting epidemics, its effect on districts in which great hospitals are placed and generally on its cost and its efficiency. It is quite possible that such an inquiry would result in upholding the present system; but even so, it might suggest checks and restrictions which are now conspicuous by their absence.

#### THE SWEATING QUESTION.

THE report of the Stores Committee of the London County Council presented at the last meeting of that body affords food for reflection of a kind far from pleasant. Whether the contract system which has been adopted by the County Council in the past, and which seems to be still in favour, is the best that can be devised on economical grounds is a question which we do not now stop to discuss. Our immediate concern, as medical journalists, is rather with the bearing which that system has on the requirements of public health. On this point statements were made by certain of the speakers at the above-mentioned meeting which were the reverse of reassuring. Under what conditions, for example, can the manufacture of trousers be conducted when such articles of apparel can be produced for 3s. 6d. per pair? Imagination revolts at the picture of squalor, wretchedness and filth, with their accompaniments of disease, implied by such surroundings as must necessarily be attendant on work so inadequately remunerated. There can, we think, be but scant disagreement amongst intelligent persons who have the material, to say nothing of the moral, interests of the people at heart that the contract system has so far and as a whole failed to be capable of being safeguarded against abuses the evils of which altogether outweigh any advantages which may be derived from its adoption, except those which accrue to the contractor. Mr. John Burns, M.P., struck a sympathetic cord when he stated "that he would continue, in season and out of season, the endeavour to stamp out sweating in connexion with every department of the work of the County Council."

#### THE LATE POET LAUREATE.

IT was fitting that the poet who was the successor of Wordsworth and the follower of a long and illustrious line of such poets as Byron, Shelley and Keats, and who for half a century has indisputably held the first place in this Victorian age, should be buried in Westminster Abbey as the last tribute of national honour and respect. If he did not always express himself in the most flattering terms of the medical profession in his verses, he did so in grateful words of personal recognition of our services. Tennyson's position and experience were unique in many respects, and profoundly affected the spirit of his conceptions, the mould in which those were cast, and the garb in which he clad them. Since time began there has probably always been a conflict—varied according to the intellectual standard and tone and the aspirations of the age—between reason and faith. But Tennyson found himself in a new world of thought. He was not only a poet and idealist, but a metaphysician and speculative philosopher. His was not a scientific caste of mind, but the doctrines and discoveries of science nevertheless forcibly impressed him. He was a profoundly religious man, but no sectarian. Reverence, a sense of responsibility, a penetrating insight into the mysteries of this world, conjoined with a firm belief in the unity of purpose and harmony underlying the varied and complex phenomena of life, never forsook him. The son of a clergyman, born into the world at a time when the finality of faith and knowledge was commonly regarded as bounded by the limits of the current creeds of the day, he grew up to manhood to find himself confronted with

an iron age—an epoch of scientific discovery and material progress,—a time for the testing and proving of all things. Profoundly perplexed at times, but always undismayed, he never failed to follow the “beam in darkness” and to “faintly trust the larger hope.” Large-minded, tolerant and tender, his belief in the nexus between things seen and unseen, and in the presence of an invisible Power in whom we live and move and have our being, was unflinching. It is the dominating idea expressed in his “In Memoriam,” in “The Two Voices,” and in his touching and beautiful lines “Across the Bar,” and traces of it are discoverable in all his writings. As we have already said, if he was below some of our greatest poets in robust strength, in vigour and originality of conception and dramatic force, he was above most of them in finished workmanship, in grace and delicacy, and in the proportion and adequacy of expression to conception. To say that he was inferior to Shakespeare is simply to state that he failed to accomplish what no other “man of woman born” has accomplished; still some of his ideas were Shakespearian. Tennyson never perhaps struck home to all hearts alike, peer and peasant, like Robert Burns, nor did he possess the supremely natural, untutored sweetness and tenderness of the bard of Scotland; neither had he the rugged strength and careless power of Byron or the creative imagination of Shelley; and nuggets of gold were not unexpectedly encountered in his writings as in those of Browning. Nevertheless, his work was always wrought by the hand of genius, sometimes into fancy’s flimsiest gossamer, sometimes weighty with a big thought, but always of the true and never of the baser metal.

#### THE CONSULAR REPORTS.

SIX years ago the present Foreign Secretary, who then occupied his present post, effected an important change in the mode of publishing the Consular Reports received at his department. Prior to that date these documents had been embodied—perhaps it would be more descriptive to say entombed—in a blue-book published at irregular intervals during the sitting of Parliament. Under the system then introduced these various reports are now published separately, with the result that they can be obtained by the public at much reduced cost, since only those particular reports need be purchased which may be of interest to the purchaser. A further advantage is that these reports are now made public as received, so that the value of their contents does not suffer the deterioration consequent upon inordinate delay which was common under the earlier system. Of the substantial benefit thence accruing to the public service there can be no question; but great as the improvement is it has involved at least one slight disadvantage which should be reckoned as a drawback in any attempt to estimate the public gain. The drawback is this: that the reports not being now published in a collected form, it is far less easy than formerly to obtain a general and comprehensive view of them. Much that would attract notice, especially the notice of a reviewer, in an annual or semi-annual volume is now passed over altogether for want of a focus in which it can be discovered. Radiating lines can easily be traced if their centre is once found, but the unconnected items of the separate consular reports have no common centre and are proportionately hard to discover. To remedy this defect an Index has just been issued from the Foreign Office, which deals with the whole series of reports issued since the change of system already referred to, and gives a large number of references, alphabetically arranged, to the documents in question. The value of such an Index cannot well be over-estimated. It will not only facilitate reference, but it will in a very large measure bring the reports themselves to light and make available for public purposes what would otherwise be the mere lumber of the Stationery

Office. The reports deal, and deal in a highly competent and authoritative manner, with a vast range of subjects in which matters bearing upon the public health and sanitation in different parts of the world occupy a conspicuous place. The Index appears to have been carefully and skilfully compiled, and if not its only, at least its most conspicuous fault is that one so common in Government work—namely, that it has been too long delayed. Now that a beginning has been made we trust that the public may look for an annual index volume. That is necessary to the completeness, and not less to the full usefulness, of the Consular Reports.

#### THE BERLIN MUNICIPALITY AND THE PUBLIC HOSPITALS.

WHILE our great London hospitals, many of which are among the finest institutions of their kind in existence, are carried on in a state of almost chronic financial deficiency, receiving but little help from the greatest, oldest and wealthiest corporation in the world, it is worth while to draw attention to what is being done by the municipal authorities of Berlin in respect of providing for the sick poor of that city. It should be ever borne in mind that no expenditure is more profitable—as none responds better to the noblest instincts of our nature—than that which is devoted to the restoration of the sick to health. The millions who live from hand to mouth, dependent for sustenance on their daily earnings, are practically helpless when overtaken by disease or accident. Not only do their earnings cease under such a calamity, but they must be entirely maintained and “doctored” at the cost either of the charitable and well-to-do or of the public rates until they are convalescent. All means of preserving and restoring health are therefore means of avoiding a huge economic loss, to say nothing of the heart-breaking and demoralising effect on the poor family when the bread-winner is smitten down with disease. The municipality of Berlin since the year 1872 has devoted itself with conspicuous energy to the practical carrying out of a wise humanitarian principle in reference to this great question. No doubt the success of its efforts is largely due to the prudent counsels of one of its most able members, the world-renowned Professor Virchow. On the three great modern hospitals of Berlin the municipality expends no less than £60,000 per annum, without taking into account the Charité, an enormous old-fashioned institution. These principal hospitals contain more than 3000 beds, most of which are free, but in some cases, where patients can afford it, they contribute wholly or in part the cost of their maintenance. The Moabit Hospital is a superb institution, and was greatly admired for its site, structure, arrangements and maintenance by the visitors to the International Medical Congress in Berlin in 1891. It was originally intended for infectious diseases only, but when wards remained unoccupied for want of infectious cases they gradually came to be utilised for various diseases. The general plan is that of a parallelogram, with thirty wards, each containing thirty beds, arranged along two sides, each pavilion having two storeys. The height of the side walk is ten feet and at the centre of the roof about fifteen feet. There are no fewer than twenty-eight windows to each ward, and air and water (the latter hot and cold) are supplied in equal abundance. The supply of water for the hospital proper is no less than twenty-four gallons per head daily, but when the amount needed for other purposes, such as flushing drains, hot-water appliances, watering of flower beds &c. is included, the consumption reaches 150 gallons per head per day. Although this hospital is most admirably fitted, and so designed and maintained as to meet every requirement, it affords a striking illustration of that “efficiency with economy” which is so much desiderated and talked of, but so rarely met with. It was erected at the very moderate cost of only a little over £100 per bed. The daily cost of patients is 2-8 marks daily, or about £60 10s. per annum

The second great municipal hospital is the Friederichshain, which was completed in 1874; the third, the Urban Hospital, was opened about two years ago. They are both handsome and well-built structures, especially the latter, which is complete in every detail, including electric lighting. It provides accommodation for 600 patients, at an expenditure of £245 per bed. The average cost of each patient in the Urban Hospital is £72 per annum, as compared with £56 in the Friederichshain Hospital and £27 10s. in the old Charité Hospital. The city does not bear the whole of this outlay, as there is an offset in the shape of payment from certain patients, donations &c., so that the actual cost to the city is reduced in the case of the Moabit Hospital to £38 4s. per annum, of the Friederichshain to £36 10s. and of the Urban Hospital to £57 10s. per annum. The medical officers of these hospitals are very well paid, especially when it is borne in mind that money goes further in Germany than in England. The principal consulting members of the staffs receive from £300 to £350 per annum, the salaries of the residents varying from £50 to £75 per annum. One of the most admirable provisions in relation to these city hospitals is the convalescent homes erected on the farms connected with the arrangements for the utilisation of the sewage of Berlin. All experienced medical men know how common it is for a patient to be actually cured and ready for discharge from hospital long before he is strong enough to resume work, while the necessities of the hospital demand that he should leave the institution. The Town Council of Berlin have recognised that a patient discharged under these circumstances is very likely to lapse into chronic, perhaps incurable, ill-health, and then become a permanent charge on the rates. They have, therefore, thought it both humane and good economy to provide a means of giving two or three weeks' country air to every patient who may need it, and the results have eminently justified their forethought. It is highly satisfactory to know that should cholera unfortunately spread in Berlin there is not only a staff of medical men second to none to attend to them, but that there is admirable existing hospital accommodation and a most active and intelligent town council not only ready to devise the best means, but also to spend money freely to meet the emergency. Municipal experiments in hospitals are not to the English mind, which is proud of its voluntary hospitals, founded and maintained by personal legacy and contribution. We should be sorry to see our hospitals become dependent either on State or rate support; but it is our duty to record what is done in other countries on a different system. Such accounts as the above should stimulate the supporters of British hospitals to double their subscriptions and to show that voluntary charity has lost nothing of its ancient power to provide generously for the poor overtaken by accident or disease.

#### THE TREATMENT OF MYXŒDEMA.

A CASE of myxœdema is now under treatment the results of which will be watched with interest by the profession. The patient is a woman aged forty, who for nearly three years has been under treatment for myxœdema. In every respect it is an extremely typical case: persistently subnormal temperature, general swelling of the integuments, dryness of skin, partial baldness, clumsiness of movement, slowness and thickness of speech &c. The patient was admitted to the Royal Free Hospital in July, under the care of Dr. Hector Mackenzie, for the third time, in order to be treated by hypodermic injections of thyroid juice. In consequence of the difficulty experienced in obtaining the latter Dr. Mackenzie was induced to try the effect of feeding the patient on fresh thyroid glands. The result has been a very striking improvement. The myxœdematous swelling has entirely disappeared, the temperature has become steadily normal, the skin moist and the speech

natural. The patient says she feels as well as ever she did in her life. The change in her appearance is such that the existence of the disease would probably not suggest itself to anyone seeing her now for the first time. At first the thyroids of two sheep were given every day finely minced. This was probably more than was advisable, because a remarkable acceleration of the pulse ensued, which lasted until the thyroids were discontinued for a time. The importance of this method of treatment is obvious. In view of the recent observations on the advantage of the thyroid juice when given in the form of injections this method would seem to constitute a distinct advance. It can be easily carried out and is free from risk, which cannot be said of the subcutaneous mode of treatment.

#### REPORTED OUTBREAK OF SCURVY.

It is stated that a French barque, the *Automena*, has just arrived at Queenstown from the Mauritius, after a protracted voyage, with four cases of scurvy on board. Other members of the crew are also said to be showing symptoms of the disease. Scurvy as a disease, it is well known, has of late years almost entirely disappeared from the vessels of the mercantile marine, only exceptional and isolated cases occurring at intervals. Even in those cases the intensity of the symptoms that characterised outbreaks many years ago is rarely observed. The cause of this decline is due in great measure to the improved provisioning on board ship, the superior quality of the rations served out, the use of fresh messes in the shape of tinned meat and vegetables, and the improved hygiene generally. Both the French and American mercantile marines were in advance of us in this matter. It was a matter of notoriety in the old days that French and American vessels were much freer from scurvy than were British ships. It is strange, therefore, that the present outbreak should have occurred on board a French vessel, and it will be interesting to learn whether the outbreak is one of true scurvy brought about by a deficiency of antiscorbutic food and of lemon-juice, or whether it is that form of "scorbutic anæmia" which resembles scurvy in many respects, but is induced by privation and exposure. At first sight it is difficult to distinguish between the two forms. In scorbutic anæmia there is the same extensive ecchymosis of the skin; hæmorrhages from the mucous membrane occur and the gums are spongy; but on closer examination we find that, though the gums are spongy and bleed, they do not develop the peculiar fibrinous growth so characteristic of true scurvy, and the fibrinous exudation found in the flexure of the joints is not present. It is also stated that night blindness, which is so common in true scurvy, is absent in cases of scorbutic anæmia.

#### MR. J. A. BRIGHT, M.P., ON VACCINATION.

THE interview which Mr. John Albert Bright, M.P., had with the Rochdale Board of Guardians on the 6th inst. cannot fail to have attracted attention, not only because of the novelty of a member of the Legislature justifying his refusal to obey the laws of his country, but even more from the fact that this gentleman occupies a seat on the Royal Commission that is engaged in investigating the very subject upon which he has apparently quite made up his mind. Mr. Bright entertains strong objections to the performance of compulsory vaccination because of the "serious injuries" which he has reason to believe follow upon it; and so convinced is he of the impropriety of the practice that, with the exception of his eldest child, who was vaccinated before its parent had taken up this position, he declines to allow his children to be vaccinated, and will bear the consequences of his refusal to obey the law. With all deference we would submit that Mr. Bright by his action has incurred a very grave responsibility, upon grounds which seem to

us both untenable and illogical. The gist of his contention is that, without denying the efficacy of vaccination as a prophylactic for small-pox, the risks of possible injury to health ought not to be incurred on the problematical chance of the child being subsequently exposed to small-pox. Supposing that this view were carried to its logical conclusion—and we fear that this is not unlikely, since the action already taken by the Royal Commission is undoubtedly the first step towards the repeal of compulsory clauses—what would be the result? We venture to say that it would inevitably issue in a return to the terrible mortality from small-pox and the almost as frightful disfigurement and mutilation that characterised the disease a century ago. It is idle to talk with Mr. Bright about enforcing primary vaccination wholesale when small-pox epidemics occur. Has he realised what that means? Setting aside the difficulty of convincing parents, even in the presence of an epidemic, that vaccination neglected in infancy is essential then, what can be expected from wholesale and indiscriminate vaccinations in a time of panic? Will not “injuries” be likely to be even more frequent than under a system which provides for the regular and systematic performance of the operation upon every member of the community? And when to this is added the misery and suffering entailed by small-pox itself upon hundreds who would be unprotected, surely it is legitimate to contrast these inevitable evils with the amount of injury from vaccination that occurs at present. Mr. Bright would sacrifice the many for the possible chances of saving the few. By all means let us inquire fully into all the circumstances attending reputed injury from vaccination, so that its performance may be rendered as harmless to the minute minority that unfortunately now suffer from it as it is to the vast majority who are vaccinated; but to cast aside this beneficent measure because of its conjunction with preventable evils is a piece of folly that would inevitably and immediately recoil on the nation that performed it.

#### THE WATER-SUPPLY OF CHESTER.

OUR attention has been drawn to the deficient and unsatisfactory water-supply of the ancient city of Chester. There is evidently strong reason for the belief in the minds of many of its inhabitants that the present water is not of the purest character, but, on the contrary, deleteriously impure. This fact must be well established when the highest ecclesiastic in the city (the Bishop) has thought fit to attempt to arouse the governing body to a sense of their duty. It appears also the Duke of Westminster is fully alive to the fact, and has assisted in inaugurating a movement to secure what is an all-important desideratum to every town—a pure and abundant supply of the first element of healthy life. It seems strange to us, and is an anomaly we cannot understand, that the corporation of an important city like Chester should be so lacking in judgment as not to take the initiative in a matter of such paramount importance as the water-supply, but leave it to outsiders to move in the matter. Cathedral towns are proverbially sleepy, and Chester seems to be no exception to the rule. No consideration of economy or social obstacle should be allowed to obstruct the provision of a pure water-supply. This is so largely a medical question that we are surprised the profession in Chester has not, as one man, risen to speak out an unqualified condemnation of bad water. The Duke of Westminster, speaking on the matter, referred “to the amount of sewage which found its way into the river, and pointed out that the water company had an admirable system of filtration, and they gave as good a supply of water as they could, taking it from a tainted and impure source. The crux of the matter was whether they could convert a supply of impure water by any means into one which should be innocuous to the community. The death-rate in Chester

in 1891 was 21 per 1000, and if the water was improved as the air had been, the death-rate might be reduced to 16 or 17 per 1000.” The Bishop of Chester, at a recent meeting, moved “That the Chester water-supply is open to such grave suspicion that steps should at once be taken either to remove that suspicion, or, if on further investigation it should be established, to seek a new and purer source of supply.” His lordship spoke of the more than suspicious character of the water, and described the Dee as a glorious boating river, but from a sanitary point of view it was a main sewer. The matter is too serious to be postponed for an indefinite time, and prompt action is imperative and paramount. We would say to Chester: Remember Bangor.

#### POISONING BY FISH.

WHEN the British steamer *Yorker* arrived at Marseilles from Rangoon the captain reported that several of his crew had died in terrible agony after partaking of some fish which had been caught in tropical waters. In these regions many fishes are found which at certain seasons, or it may be in the case of some species always, are exceedingly poisonous when used as food. This is especially the case with such fish as feed on medusæ and on certain coral banks. Experts assure us that great caution has to be observed in eating fish caught in tropical waters, and too much attention cannot be bestowed on the warnings of those whose experience of the fish found in various neighbourhoods enables them to say which should be avoided as articles of diet. This subject is fully discussed in some of the earlier chapters of Gunter's “Fish,” a copy of which is to be found in the library of the Royal College of Surgeons.

#### THE NOTIFICATION OF DISEASES AT LINCOLN.

IN a letter from the Local Government Board to the Lincoln urban sanitary authority the Board say: “The Board do not understand why the Town Council of Lincoln have not adopted the Infectious Diseases (Notification) Act, 1889, which has been adopted in nearly all the great cities of the kingdom, nor do they see why the necessary steps with a view to the adoption of the Act should not now be taken.” In the discussion which followed the members of the Lincoln Town Council expressed satisfaction with their low death-rate, and Alderman Maltby, in a slightly jocular tone, expressed his belief that the deputy town clerk would take special care of the Board's letter. The worthy alderman seemed willing to have notification if medical men would do it voluntarily, which we take to be another term for gratuitously, and another member said he would like the Act adopted so far as not to involve the removal of patients to hospital.

#### THE ABERDEEN ROYAL INFIRMARY.

THE new wing of the Royal Infirmary, Aberdeen, was opened by the Princess Louise on the 4th inst. The new Royal Infirmary is a memorial of the jubilee of the reign of Her Majesty the Queen, and our readers may be interested by a few particulars in regard to it. Mr. Saxon Snell's design was selected. The surgical block consists of four storeys, three of the upper storeys being for wards and the necessary offices in connexion with them. *En passant* we may remark that we presume the height of the building is attributable to the limited amount of ground space available. The total number of beds for surgical cases is 140. The nucleus of the block, measuring fifty-five feet by thirty-eight feet, contains staircase, hydraulic lift, patients' clothes store, bath-rooms, ward kitchens, surgeons' and sisters' rooms &c. Right and left of this centre block are the surgical wards. The female wards each measure twenty-two feet by twenty-seven feet and a

half. The floor space allotted to each patient is ninety square feet, the air space 1400 cubic feet. Each ward has accommodation for thirteen patients on the female side and nineteen on the male side. In one male ward there is accommodation for twenty-five beds. Small wards with six beds are provided for special cases. Each ward has small projecting wings for sink, lavatories and sanitary adjuncts. All the ward floors are fireproof, of coke breeze concrete upon rolled iron joists; the floors are of Canadian maple in narrow width, and are of wax-polished and impervious surface; the walls are of cement plaster finished with parian; all the passages, corridor, roofs and staircases have a dado, four feet six inches high, of parian cement; all angles are rounded; the staircases are of stone, the ward windows are all alternately draw-sash and French casements; rounded balconies face the airing yard to allow of patients getting an airing. The hospital is heated with hot-water pipes. The ventilation includes the admission of heated air into the wards and the discharge of vitiated air by appliances of the latest and most approved types. The buildings will be lighted throughout with the electric light.

#### PROFESSOR BILLROTH'S JUBILEE.

THE past few days have witnessed a series of festivals at Vienna in commemoration of the commencement of the teaching career of Professor Billroth at the above-mentioned school. The event indeed has been converted into a sort of congress, which was inaugurated on the 8th inst. by the assembling of the former pupils of this distinguished surgeon in order to testify their gratitude for the advantages they had derived from his instructions. On this occasion Professor Czerny of Heidelberg was deputed to present to Professor Billroth a volume containing a record of his principal surgical works, and entitled "Contributions to Surgery." In the evening of the same day a dinner was given to Professor Billroth, at which numerous congratulatory speeches were made. The jubilee extended to the 11th, on which day his friends and admirers assembled to listen to an address by Professor Albert. The commemoration has excited great enthusiasm in the medical world of the Austrian capital.

#### ABUSE OF EYE HOSPITALS BY WEALTHY PEOPLE.

A CORRESPONDENT in an evening contemporary writes apparently in justification of wealthy persons going into the ophthalmic hospitals. He says, "The reason why people go to the Ophthalmic Hospital is because, however much wealth they may have, they get the best surgical treatment." This follows, somewhat inconsistently, an account of his own experience of the hospital, with which he was dissatisfied. He adds, "I believe it is quite true that very rich men go to the Ophthalmic Hospital. An Australian landowner was in when I was. He had come from Australia for the purpose." Wealthy and well-to-do people who go to hospitals are without excuse. They are not objects of charity and they take up beds meant for the poor. It is idle to say that the best surgical treatment is there. It is also to be had from the same surgeons privately; and it is mean and unjust not to pay for it. Such public statement of abuses of eye hospitals should make the governors more vigilant to exclude such unfit cases. Otherwise subscriptions will fall off.

#### THE HOWARD SOCIETY'S REPORT.

THE wise and practical benevolence which characterised the great prison reformer is commonly represented in the proceedings of the Society which bears his name, and of this fact we have received fresh proofs in its recently published annual report. While admitting, however, the general excellence of the matter contained in this work, we may select certain subjects with which it deals as of special interest and importance. Among these public opinion will rejoice to note

as a familiar evil marked for amendment the notorious inequality of legal sentences. No one probably will dispute the pernicious effect of that kind of magisterial good nature which has often impeded justice by condoning grave personal errors—as cruelty, drunkenness and the like—while scourging by heavy penalties the most petty sins against property. The report again strikes hard at the system of "association" among prisoners still widely practised in America and by no means unknown in Europe, or even in Great Britain and her dependencies. It would institute everywhere in place of this a method which would separate prisoners from each other while allowing them intercourse by visitation with the non-criminal outer world. It exposes with critical penetration the fallacy within that emasculated humanity which educates, feeds and clothes, but will not chastise, the offender against law. The frequently long detention of prisoners awaiting trial and their unwholesome and indecent herding together in many court-houses have given rise to protests on the part of the Association which have not been fruitless of improvement. Not the least sensible observation contained in the report is that which condemns the still too common imprisonment of children and youths, for whose misdemeanours a more effectual deterrent would usually be found in the free administration of the birch.

#### THE SEMMELWEISS INTERNATIONAL MEMORIAL.

WE have already informed our readers of the movement on foot for the erection of an international monument to Semmelweiss. We gladly revert to the subject, and direct the attention of our readers to the notice of a meeting to be held on Oct. 24th, at 5 P.M., in the library of the Royal College of Physicians, and to be presided over by Sir Andrew Clark, Bart., President of the College. We earnestly trust that he will then be supported by practitioners of every class, and not least by general practitioners who feel grateful to Semmelweiss for shedding such a flood of light on the simple means by which the conveyance of puerperal fever may be avoided, of which means the more perfect obstetric antisepticism aimed at by every good practitioner is the consummation. It is understood that subscriptions will be limited to one guinea. There will be the more need for numbers. We wish every success to the movement. It is understood that the practitioners of Scotland and Ireland will be asked to participate.

#### DIPHTHERIA AT ALBRIGHTON.

A STORMY meeting of the parishioners of this place, situated in the Shifnal rural sanitary district, took place recently, to discuss the sanitary state of the village, which had been blamed for the prevalence of diphtheria. Various allegations were made as to the circumstances of the drainage, sewage disposal and water-supply which, if true, deserve the earnest attention of the authority. But, inasmuch as some divergence of opinion appeared to exist as to the facts, the matter seems one that requires the intervention of the Shropshire County Council or of the Local Government Board.

#### THE SOCIETY OF MEDICAL OFFICERS OF HEALTH.

THE Birmingham and Midland Branch of the Society of Medical Officers of Health held last week its first meeting of the present session, and Dr. Alfred Hill, the President of the branch, read a paper on Cholera, giving an account of the different invasions of England by this disease, and especially of cholera prevalences in Bilston, and he contrasted the calamities that occurred on these occasions with the immunity enjoyed by England at the present time. The circumstances under which cholera was spread were, he said, well understood in this country, and he dwelt upon the evidence that went to prove that cholera was a water-borne disease. The dangers

of surface wells were described, and an account given of the steps taken in Birmingham to close those wells which were found to be polluted. The lesson Dr. Hill taught cannot be repeated too often. England is undoubtedly in a better condition to resist cholera now than formerly, but the work is in no way completed, and there are still in existence localities where excessive death-rates from enteric fever show that there cholera would still find fitting places for its development. The winter months give opportunities for sanitary authorities to remove many of these dangers before injury results. It is to be hoped that this opportunity will not be wasted.

#### SMALL-POX PREVALENCE.

SOME forty to fifty cases of small-pox per week are still being reported throughout the kingdom. The town of Warrington retains the preëminence of contributing the largest quota of these, equal to nearly half the total. Halifax and Barnsley come next, whilst London, it is satisfactory to know, remains practically free from the disease, only some half-dozen cases remaining under treatment.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Berlin.*—Dr. Johannes Sobotta has been appointed Assistant in the First Anatomical Institute.

*Dorpat.*—Dr. Gustav Tammann has been appointed Extraordinary Professor of Chemistry in succession to Dr. Carl Schmidt, who has retired. The total number of students in the university is 1558, or more than a hundred less than last year. Of these rather more than half belong to the medical faculty, in addition to 118 who are studying pharmacy.

*Innsbruck.*—Dr. Foltanek, the newly appointed Professor of Children's Diseases, has resigned his post on the ground of the insufficient accommodation provided for patients.—Dr. Wladimir Lukasiewicz has been appointed Extraordinary Professor of Dermatology and Syphilis.

*Kazan.*—Dr. Alexander Henrichovich Ge, Professor of Dermatology, has been appointed Dean of the Medical Faculty.

*Königsberg.*—A new Clinic for Syphilis is being established under the care of Professor Schneider. Hitherto there has been no Clinic for Mental Diseases, but this deficiency is now being supplied by the establishment of one as a department of the Town Hospital under Professor Meschede. The Prussian universities have now all, with the single exception of Kiel, a Clinic for Mental Diseases.

*Würzburg.*—The chair of Chemistry vacated by Dr. Fischer, who has gone to Berlin, has been offered to Professor Hantzsch of the Zurich Polytechnic.

*Zurich.*—The chair of Pharmacognosy and Pharmacy, vacated by Dr. Schür—who goes to Strasburg to fill Fluckiger's place—has been conferred on Dr. Carl Hartwich of Brunswick.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Eduard Ipsen, Professor of Orthopædic Surgery in the University of Copenhagen and Surgeon to the Crown Prince of Denmark, at the age of forty-eight.—Dr. A. Allenstein, one of the best known practitioners in Riga.—Dr. Steintal, Medical Privy Councillor of Berlin.

WE regret to learn that Dr. Villemin died on Friday night, Oct. 7th, at the age of sixty-five. Born in the Vosges, he began life as a teacher in the Strasburg Military School and was next professor at Val-de-Grâce, Paris. His works on Tuberculosis were the starting point of new ideas on that malady. His experiments proved it to be inoculable and contagious. At the International Tuberculosis Congress in Paris last year the greatest honours were paid to him,

THE Smith Hospital, Henley, the gift of the late Right Hon. W. H. Smith, was opened on the 6th inst. by the Bishop of Oxford, in the presence of a large audience. The site for the building was given by Mr. W. D. Mackenzie of Fawley Court, who has undertaken to lay out the ground.

PROFESSOR ANREP of St. Petersburg is stated to be suffering from cholera, but is believed to be progressing favourably.

## CHOLERA.

#### CURRENT NOTES, COMMENTS AND CRITICISM.

CHOLERA is gradually ceasing to manifest itself with epidemic force, and it is rapidly subsiding in those places in which it is still prevailing. At Hamburg there were only 13 cases and 3 deaths on the 11th inst., and for the week ending Oct. 8th the number of attacks was 155 with 43 deaths, against 474 and 180 respectively during the preceding week. The number of cases in Paris and its environs is diminishing, but there has been rather a sharp outbreak at Marseilles. At Antwerp, Amsterdam, Rotterdam, St. Petersburg, Berlin and Cracow respectively the cases are relatively few in number. At Budapest the disease still continues prevalent, as might be expected, and several isolated cases are stated to have occurred at thirteen different places in Hungary.

In the case of an epidemic disease like cholera, disappearance and death cannot, however, be used as conterminous or synonymous expressions. It does not at all follow, unfortunately, that because the disease ceases to manifest itself actively under the repressing effects of winter its cause will not be revitalised under other and favourable conditions. The influence of season on epidemic cholera is a noteworthy factor. It apparently overrides other conditions, and we might almost as soon expect a heavy fall of snow in summer as the beginning of an epidemic of cholera or its rapid and widespread extension in winter. But the active manifestation of the disease is one thing, its death and destruction another. As we have stated from the beginning, a cholera epidemic usually lasts three, or from three to four years from start to finish, and the experience derived from the history of cholera in the past indicates that it has its periods of latency and dormancy as well as those of active manifestation; and it is not only quite conceivable, but probable, that the former has a causal connexion with the latter period in the spread of an epidemic. Paradoxical as it may appear, it is well to regard the cholera-cause for the moment as something altogether separate and distinct from the human beings in whom it manifests itself and makes its presence known; for there can be little doubt that the time of its coming forward may be quite separate and distinct from the time of its introduction and distribution in any given country or locality. So much depends upon season and other conditions, to say nothing of those of locality, which may be favourable or the reverse, that we cannot prospect future occurrences with any sufficient accuracy to turn them to practical account. But of one thing we may be sure—viz., that it is a delusion and contrary to fact to suppose that because an epidemic declines or ceases altogether in winter its further progress at later dates and under other circumstances is therefore arrested and cannot take place.

As on former occasions, the present epidemic has been very unequal both in its incidence and in its effect in different places. In Russia it has given rise in the aggregate to a terrible amount of sickness and mortality. The total number of cases in the Caucasus during the months of August and September were 127,273 with 64,767 deaths, according to a telegram in the *Daily Chronicle*. Although the epidemic had almost died out before August in the government of Baku, 1800 deaths were reported during that month. In the Northern Caucasus the provinces of Kuban and Stavropol suffered most heavily. In Baku the death-rate was 70 per cent. of those attacked, while in Kars and the surrounding district it was 40 per cent. At the present time the disease is very active in the government of Erivan and to the north of the Caucasus. During the seven weeks of the epidemic in Hamburg 17,862 persons were attacked with cholera, with 7571 deaths, or a mortality of 42 per cent.

There are still several gaps that have to be filled up and some obscure points on which more light has to be thrown before we can be said to be in possession of anything like an accurate and complete history of this epidemic. The literature on the subject is voluminous enough, but we require to have all the facts chronologically set forth before we are in a position to separate the real from the assigned or hypothetical causes of its spread. To begin with, we require to have this information in regard to the epidemics in France and Russia respectively and their relation to one another, if any, and to the events which subsequently followed. Then, again, the official recognition of the disease in any given place often follows very tardily on the occurrence of the earlier cases. The names cholera nostras, cholera and choleraic diarrhoea are convenient labels but they are nevertheless embarrassing. In what relation do these stand to the epidemic disease which they sometimes precede and often accompany? Cholera presents such characteristic symptoms and is attended with such a high rate of mortality that it cannot be very well mistaken. A large number of bacteriological investigations have now been made, and we should be in a position to state definitely whether the comma bacillus has been invariably found in cases of Asiatic cholera and at what stage of that disease, whether the same micro-organism has been discovered in cases of so-called cholera and choleraic diarrhoea, and whether there are any varieties of the bacillus and their relation to these pathological congeners of true epidemic cholera. Such severe and circumscribed outbreaks of the disease as those which occurred at Nanterre, near Paris, and at the little fishing village of Le Portel, near Boulogne, should be thoroughly investigated, and an exhaustive inquiry should also be instituted in regard to the cause of the disease in the two first cases that occurred at the Runnelsburg workhouse in Berlin, for the sanitary condition of that institution is stated to have been very good, and the hypothesis that the patients contracted cholera from working on the sewage farm appears to be untenable, because they had not been at work there for three weeks before they were attacked. It is very important also to follow out the origin and progress of the disease in a village or small community of people where all the facts can be much more easily ascertained than in a large and crowded town. Assuming that Koch's comma bacillus is the cause of cholera, an explanation is required as to how it first of all was introduced into the well or water tank of a village household or institution, or into the water-supply of a village or small town, and among the large number of places that have suffered from cholera there should be some offering facilities for carrying out an investigation of this kind.

## THE CHOLERA IN FRANCE.

(FROM OUR SPECIAL CORRESPONDENT.)

### VISIT TO ROUEN.

**HIGH RATE OF INFANT MORTALITY.—ENDEMIC AND EPIDEMIC TYPHOID FEVER AT ROUEN.—SUBSOIL CONTAMINATION.—FOUL WATER.—INEFFICIENT DRAINAGE.**

SOME four years ago a Bureau d'Hygiène was instituted at Havre and endowed with the munificent income of £40 per annum! Practically this just covers the cost of publishing the vital statistics of the town. Insignificant as this sum may seem, nevertheless it has sufficed to render great service. Under the skilful direction of Dr. G. Panel, chief of the Bureau d'Hygiène, publicity has been given to the deplorable condition under which Rouen is placed. At least one most important fact has been clearly elucidated—namely, that in respect to infant mortality Rouen has the highest death-rate of any town in France. Of the children born at Rouen one-third die during the first year of their existence. Of course, this very materially effects the general death-rate. The following are the figures for the year 1891, and, so far as Rouen is concerned, they correspond with the average of the previous four years: 961 infants died in 1891; the average for the last four years was 956. Taking the fifty-one towns of France which have a population of more than 30,000 inhabitants, the general death-rate was 25.61, but the general death-rate for the town of Rouen was equal to 35.32 per 1000 of the population. The death-rate for the fifty-one principal towns of France from zymotic diseases was

equal to 1.74 per 1000, for Rouen to 1.73 per 1000. The death-rate from phthisis for the fifty-one towns was 3.40, for Rouen 4.84 per 1000. The infant mortality for the fifty-one towns was 4.27 and for Rouen it reached the very high figure of 9.02 per 1000 of the population. Thus, the infant mortality of Rouen is twice as high as the average of the fifty-one principal towns of France. These figures are not to be explained away by attributing the high death-rate to a high birth-rate. The birth-rate at Rouen is equal to 26.14 per 1000 and the infant death-rate to 9.02. The birth-rate at Paris is 27.04, infant mortality 3.55, St. Étienne, 28.74 and 3.94 respectively; Rheims, 29.55 and 6.76; Marseilles, 30.70 and 5.29; Havre, 33.49 and 6.56. The five towns mentioned have, it will be seen, a birth-rate much higher than Rouen, and yet their infant mortality is considerably less. The comparison may be set forth in percentages thus: For every 100 births in Paris there are 13.10 deaths of infants under one year of age, at St. Étienne 13.72 per cent., at Marseilles 17.22, at Havre 19.61, at Rheims 22.88 and at Rouen 34.68 per cent. For the fifty-one towns the average percentage per 100 births of infant mortality is 14.00, for Rouen 34.68. Nor does the placing of the children outside the town to nurse account for these figures, though it is an important factor in modifying the death-rate. Here are the figures: first, the percentage of children sent to nurse outside the town; secondly, the number of deaths per 100 births of infants below one year of age. At Lyons, where 42.40 per cent. of the infants are put out to nurse, the infant mortality is 12.05 per cent.; Paris, 29.76 and 13.10; St. Étienne, 20.42 and 13.72; Nantes, 18.25 and 19.11; Rouen, 13.35 and 34.68; Marseilles, 12.85 and 17.22; Havre, 10.65 and 19.61; Nancy, 6.84 and 20.05; Amiens, 2.21 and 21.20; Rheims, 0.03 and 22.88. Thus the infant mortality increases in the inverse ratio to the sending of the children out to nurse, and Dr. G. Panel calculates that, if we take into consideration the number of children born in Rouen and the proportion sent to nurse outside the town, the infant mortality there should be 18 per cent. of the births, whereas it is equal to 34.68 per cent. Further, if no children were sent out of Rouen, if all remained in the town and all died at the same rate as those that are not sent away, then the infant mortality would equal 39.29 per cent. of the births. Thus, though the figures may be twisted in all directions, the fact remains that at Rouen not only is there a higher infant mortality than in any other French town, but this mortality is extraordinarily high.

In connexion with the high infant mortality, it is perhaps useful to note, as bearing upon the present cholera epidemic, that typhoid fever is endemic at Rouen. The number of deaths from transmissible diseases for the years 1888, 1889, 1890 and 1891 was as follows:—From whooping-cough: 11, 14, 3, and 16 respectively. From diphtheria and croup: 61, 59, 47, 43. From erysipelas: 19, 8, 14, 8. From influenza: 0, 0, 40, 21. From measles: 43, 103, 15, 35. From scarlet fever: 14, 2, 0, 8. From small-pox: 10, 17, 2, 0. From typhoid fever, 87, 51, 102, 83. These figures give evidence of the endemic character of typhoid fever at Rouen. But if the statistics of the present year are studied, it will be found that typhoid fever assumed an epidemic intensity just at the time when cholera also made its appearance in various parts of France. Further, it will be noted that what is classed as "diarrhoea, gastro-enteritis and atrepsia" became epidemic at the same time. Under this latter heading the deaths at Rouen this current year were as follows: January, 42; February, 39; March, 34; April, 52; May, 45; June, 45; July, 110; August, 161. This last figure comprises 24 cases classed as cholera nostras or choleraic diarrhoea, and, over and above the 161 deaths for the month of August, there are 17 deaths entered under the heading of Asiatic cholera.

In giving at such length the vital statistics of Rouen, my object is to emphasise the exceptionally insanitary condition of the town and to throw out the suggestion that the inhabitants of the town who survive this state of affairs are to a great extent acclimatised to bad sanitation. Then those local conditions which render typhoid fever and diarrhoea so prevalent and so fatal are the favouring causes that facilitate the development of cholera. The possible consequences are terrible to contemplate if each individual case of cholera is not isolated, and if the disinfection is not complete. To make matters worse, a large number of cases of cholera are brought to Rouen from the surrounding rural districts; yet the sanitary condition of the town is such that the dictates of common prudence should

have suggested the necessity of keeping at a distance all possible cause of specific contamination. The first case of cholera noted at Rouen came from the outlying district of Bapeaume, situated to the west of the town and about a mile from the Seine. The man was ill, and went to a house in the Rue des Renards, which is not far from the hospital to which he was removed and where he died on July 21st. A few days later three deaths occurred in the same street in the house of a coal dealer. The inhabitants are fairly well off and lived comfortably in a clean house; but their cistern, containing rain water, was very dirty; and it is said that the first victim, a child, had drunk water from this cistern. A sempstress also died from cholera in this same street. Before the occurrence of the case imported from Bapeaume there had been, on July 18th, four doubtful cases. At the Ministry of the Interior at Paris there was found no record of these deaths from cholera occurring in July. The first case mentioned for Rouen bears the date of Aug. 23rd. Then on the 26th there were 2 deaths, 4 on the 28th, 1 on the 29th, 4 on the 30th, and 1 on the 31st. Altogether 13 deaths for August, whereas the statistics published by the Rouen Bureau d'Hygiène acknowledges 17 deaths from Asiatic cholera and 24 deaths from cholera nostras for the month of August. At the Ministry of the Interior I found a record of 25 deaths from cholera for September, 5 for Oct. 1st, and 2 and 3 for the next two days; while at Rouen, I was told, there had been from the 3rd to the 8th four more deaths, making 15 deaths in all, for the first eight days of October. This record, though probably not complete, suffices to show that, in proportion to the population, the epidemic is more severe in Rouen than in Paris.

In describing the cholera epidemic in Paris I have had to mention at length the consequences of the deplorable division of authority, between the Prefecture of Police and the Prefecture of the Seine. At Rouen there is no rivalry of authority, but a very confusing and unnecessary multiplicity of authority. Thus if a death from cholera occurs it is declared to the registrar of deaths at the Town Hall. A case of cholera is reported to the Bureau d'Hygiène. The latter office informs the general secretary of the municipality what has to be done. This official is the connecting link between the different services. First the police have to disinfect the room of the sick person. For this purpose there are two portable stoves which used to go to the houses, and the bedding was disinfected by steam superheated under pressure. Within the last few days the infected clothing &c. is conveyed by closed carts to the hospitals, where larger but stationary stoves have been established. The police agents disinfect the premises by spraying the walls with a mercurial solution. The apparatus used for this purpose is the same as that employed in Paris. At first Dr. Panel accompanied these police agents to see that they disinfected the premises with the necessary care and thoroughness. If, however, as is always the case where there is a question of cholera, the closets have to be disinfected, then another authority has to intervene. This service belongs to the architect of the town, and he has his staff of disinfectors for closets. Then should it be judged necessary to disinfect the yards, the wells in the yard, to make any alterations affecting the sewers, the streets, in fact anything outside the house, a third authority has to be convoked, that of the town engineer. But, as is most generally the case, if the patient has to be removed to the hospital, or if it is necessary to give relief to the family, then yet another authority must be summoned—namely, the administration of the hospitals or the poor relief authority. Then if the drinking water has to be analysed the municipal laboratory takes the matter in charge, while for bacteriological examination the specimen of water is sent to the hospital. Thus there are for scientific advice and statistical record the Bureau d'Hygiène; for disinfection of the room, the police; for disinfection of the closets, the town architect; for disinfection of the yards, the streets and sewers, the town engineer; for removal to the hospital and charitable relief, the administration of the hospitals; for water analysis, the municipal and the hospital laboratories. That the necessary work should have been done harmoniously thus far speaks well for mutual forbearance and the amicable disposition of the chiefs of the various departments, but it is nevertheless obvious that such subdivision of the work is as wrong in principle as it is clumsy in practice. It is due to the simple fact that the Bureau d'Hygiène is quite a recent creation, and it is a somewhat delicate matter to withdraw from existing functionaries a part of their functions.

Whether it be the want of a central and unique authority

or the ignorance and indifference of the inhabitants, the fact remains that Rouen is one of the most insanitary towns in France. This is all the more reprehensible, as there is little or no excuse for such a deplorable state. An excellent water-supply is available. M. Gogear, the town engineer, exhibited in the Sanitary Section of the Universal Exhibition of 1889 a scheme for the drainage of the town which showed that there were no local topographical difficulties of an exceptional character. The drainage of Rouen is practicable, an abundant supply of pure water is available, yet the town is not drained and the people drink foul water. In 1870 water was obtained at the source of the river Robec, a subterranean aqueduct of 6000 metres built, and spring water brought to a reservoir 60 metres above the town of Rouen. Five reservoirs hold a reserve of 29,000 cubic metres of water. These works were completed in 1885 and cost £204,000. Water pipes have been laid in every street. There are 212 public fountains, 810 hydrants for watering the streets of 0.04 metres diameter, and 88 for fires of 0.10 metres diameter. But, most unfortunately, the town instead of keeping these water works in its own hands, let them out to a private company, and a clause was introduced in the contract that the company was to augment the supply whenever the need of such increase was manifest. Now that the enterprise is in private hands it is not possible to compel the inhabitants to subscribe to the water-supply. On the other hand, the company has a sufficient number of subscribers to make the enterprise pay. If the number of subscribers was considerably augmented, new works would have to be undertaken, and the company does not care to face the risk of a large outlay for an increase of the supply; therefore it charges no less than £12 for placing a house in communication with its water mains. The gas and electric companies are glad to establish a connexion between a house and their supply gratuitously, and look to the annual subscriptions to cover the cost of the primary outlay. There are houses in Rouen that are not worth the cost of supplying water; for, apart from the £12, there is the annual subscription, which is rarely less than £1 12s. Thus it is that, out of the 15,000 houses which constitute the town of Rouen, only about 3000 houses are supplied with the pure water provided by the company.

The majority of the inhabitants drink rain water or well water. The rain water, after having washed the roofs of the houses, is scarcely clean; it is kept in cisterns and deprived of air and of light. The cisterns are but rarely cleaned. It would be necessary to empty the cisterns to clean them, and the inhabitants would have to wait till it rained again before they could obtain water to drink. In dry weather, when the cisterns are nearly empty, the dirt at the bottom is stirred and mixes with the water, which is then often totally unfit for consumption. Apart from the cisterns for the rain water there are numerous wells. Fortunately the water in a great number of these wells is so excessively foul that it cannot be drunk; thus, in the excess of the evil, some security is found. Many houses have three water-supplies: first, the company's drinking water, then cistern or rain water for washing, and finally well water for scouring the yard and pavement. Others have a fourth supply, that of the Seine water, which is generally used for the boilers of engines.

That the water in the wells should be extremely foul will seem only natural when it is considered that up to the year 1883 every house was allowed to drain into a cesspool so constructed as to allow all the liquids to filter away through the subsoil. At last, on March 5th, 1883, a municipal decree ordered that all cesspools should be rendered water-tight. Yet, though nine years have now elapsed, only about 5000 out of 15,000 cesspools have been visited and constructed according to the rule. But the town engineer himself recognises that in many cases when the inspector had verified that the cesspool was water-tight the workmen were made to return and with a few blows from their pickaxes destroy the bottom of the cesspool so as to enable the liquids to escape as usual. These cesspools on an average have a cubic capacity of 10 metres, and can therefore store 150,000 cubic metres of excremental matter under the houses and in close proximity to the wells. The emptying of the cesspools costs 4s. the cubic metre. The pneumatic system of emptying is employed, but the depot is within 1800 metres of the town. Here are large tanks, constructed by building up embankments, where the contents of the cesspools are exposed to the open air. It is necessary to evaporate 95 per cent. of liquid to produce the *poudrette*, which is sold as manure. To prevent the tanks overflowing and to dry the matter more

promptly some of the water is pumped away and simply thrown on to a neighbouring field, where it befouls the soil. Some 30,000 cubic metres of the foul matter which has previously sojourned in cesspools for about twelve months is thus treated annually in the open air and causes an intolerable nuisance.

Rouen has a few sewers; some are old and badly built, others are new and well built. The main sewer of the Boulevard Gauchois has an invert of 1 m. 25 c., which is so large in comparison to the volume of water received that deposits accumulate and foul odours are engendered. Other and older sewers have openings into the streets so badly contrived that the dirt thrown into them from the street does not fall into the sewer, but remains suspended half-way between the street and the sewer. This of course causes much annoyance and many offensive odours, which may be noticed when walking along the thoroughfares. All these sewers, old and bad, modern and fairly good, measure 42 kilometres. The total length of the streets of Rouen is 560 kilometres; thus only one quarter of the streets of Rouen has sewers. The houses in the streets without sewers drain into the gutter; the slop water and the kitchen water flow down the open street.

M. Gogcard, the town engineer, in his drainage scheme for Rouen, does not fall into the error, so common in France, of proposing large sewers. He advocates small self-cleansing pipe sewers, which are at once cheaper and more sanitary. There are lands near at hand available for the creation of sewage farms, and thus Rouen might be properly drained, cesspools abolished and the Seine no longer contaminated by sewage water. It must of course be obvious that at present the Seine is contaminated. The subsoil drainage, befouled by at least 10,000 leaking cesspools, must ultimately reach the Seine, and such sewers as exist have their outfall into the Seine. There are also 250 houses that drain directly into two little rivulets, which reach the Seine after passing through a part of the town. The water of these rivulets is extremely foul, as they receive the drainage from works and factories.

Since the outbreak of cholera an order has been given forbidding bakers to use well-water for the making of bread. It was found that, out of 103 bakers, only thirty-one subscribed to the water company. The police, profiting by the alarm caused by the cholera, have gone the round of the bakers' shops and have closed and sealed the wells, so that quite a rush on the water company is being made by bakers who are now compelled to subscribe. The Committee on Unwholesome Dwellings has also shown activity and there has been much cleansing of dirty quarters and sprinkling of disinfectants. Anyone, however, who has seen the Rue du Rosier—a name that must have been "wrote sarcastic"—the Rue du Petit Mouton and other such thoroughfares will acknowledge that the houses there can never be rendered wholesome. They must be rebuilt and the streets widened. There are streets in Rouen that are barely more than a yard wide. There are many dwelling-rooms that from year's end to year's end never receive a direct ray of sunlight. There are people who are content to live in the most dirty and miserable surroundings. Since the outbreak of cholera a good deal of out-door relief has been given, but this can never make up for the organic defects that prevail.

To sum up, at Rouen only one house out of five—3000 out of 15,000 houses—has a supply of wholesome drinking water; only one cesspool out of three cesspools has any pretence to be water-tight; more than 10,000 cesspools allow their foul liquid contents to escape in the subsoil; out of 162 kilometres of streets only 42 kilometres of streets have sewers. Many of the streets are devoid of sunlight. The sewers—the surface drainage—poison the confined atmosphere. What wonder that the infant mortality is the highest in France and that the general mortality reaches the alarming figure of 35.32 per 1000 of the population. What wonder that typhoid fever is endemic, that diarrhoea has assumed an epidemical intensity, and that cholera has found in Rouen ready victims. May the mischief go no further and may the warning be taken in time. Good water is available, good drainage is possible; both should be at once secured.

#### CHOLERA IN GERMANY.

Our Berlin correspondent writes:—The numbers of cholera cases and deaths in Hamburg from Sept. 30th to the 8th inst. were 357. On the 9th inst. 300 architects visited the new Hamburg waterworks and were almost unanimous in their praise and in blaming the slowness

with which the work of their completion is going on. Dr. von Gossler, ex-minister of educational, ecclesiastical and medical affairs, now President of the Province of West Prussia, has been appointed Commissioner of Public Health for the Vistula and its tributaries. The teachers in the village schools in the governmental district of Potsdam have been ordered to teach the children what to do and what to avoid in cholera times, and to carry out these instructions by means of short dictation exercises. At the last meeting of the Berlin Society for Internal Medicine the subject of discussion was cholera. The President, Professor Leyden, summed up the experience of the last decades concerning outbreaks of this disease, and showed how far opinion regarding it and the measures employed against it had been influenced by Koch's discovery. Dr. Paul Guttman, chief physician in the Moabit Hospital, to which all the Berlin cases have been taken, reported his experience. The cases had been 30 in number, and in 25 of these relations with Hamburg were proved beyond doubt. The great majority of the patients were bargemen and their families; and in all these cases, as well as in 2 of the 5 cases not traceable to Hamburg, the drinking of infected river water was proved to be the cause. Besides these real cholera cases the Moabit Hospital had to receive all suspects. One person of the latter class, in whom there was little to notice at first, fell ill of cholera after a short time. An important observation was that some patients who seemed to have nothing worse than diarrhoea were found to be suffering from genuine cholera, on which ground Dr. Guttman exhorted his professional brethren to send even apparently harmless cases of intestinal disorder to hospital in cholera times, because speedy and effective bacteriological examination was impossible elsewhere. He gave a minute description of the post-mortem phenomena in cholera, which were generally very characteristic.

A correspondent in Hamburg writes:—The Hamburg epidemic, though declining, still produces cases of the most virulent type. Up to the present time the official reports, which certainly do not over-estimate the mortality, state the number of cases that have occurred to be 17,673, with 7522 deaths, which would give for the entire population 44 per 1000 attacked and 19 per 1000 deaths, with a mortality of 42.6 per cent. of those attacked. All classes and all parts of the town have suffered, though, as might have been expected, the poorer and most crowded neighbourhoods were affected most. The form of cholera has scarcely undergone any change. The disease usually ends in a low form of "typhus," as it is called here. Eruptions are not frequently seen. There has been considerable activity displayed in attempting to stamp out the disease, though there has been nothing very worthy of note in the methods. The town is divided into districts, each of which has a medical officer constantly on duty for the service of the sick. A case is at once notified by telephone to the authorities. If the patient is willing, he is at once removed to a cholera hospital in an ambulance and the house is then disinfected. Any soiled linen is sent to the disinfecting house. Should the patient die, the body is removed to a special mortuary. Should a dwelling prove a veritable pest-house by repeated cases occurring the inmates are removed to another residence by the police. Boiled water is supplied from boilers which are placed in sheds in the middle of the streets, and disinfectants are supplied freely and gratuitously to all who apply for them.

The authorities are discussing the question of a new water-supply for the town. It has now been determined to continue to employ for drinking purposes the water of the Elbe, which contains all the sewage of Magdeburg, a city of 160,000 inhabitants, instead of going some forty miles to the north-east to the splendid Holstein lakes. No doubt economy is the reason, a quality for which Hamburg is celebrated. The newspapers are full of the treatment awarded to some medical candidates from the German universities who came here to take charge of the sick. They were told they would receive 20s. a day, but the moment the epidemic began to decline and it was considered desirable to diminish their number they were tendered 3s. 4d. a day—the pay of a day labourer—and when this was indignantly declined they were dismissed peremptorily with nothing. The Hamburg authorities have had to pay the common working men who removed the sick &c. 15s. a day. This action has not tended to increase the sympathy felt for the town in the rest of Germany.

CHOLERA IN AUSTRIA-HUNGARY.

Our Vienna correspondent writes:—The outbreak of cholera remains sporadic in the district of Cracow. Only a small number of new cases were reported to have occurred there during the last week. The Cracow outbreak has the character of a house epidemic, and most of the cases have been brought to the cholera hospital from one street. These houses are kept under strong quarantine by military force. Some cases of cholera were also stated to have occurred in the villages near Cracow. By the quarantine measures the trade and traffic at Cracow are reduced to a minimum, and people in Austria begin to understand that insanitary conditions sometimes become very expensive. At Budapest the cholera is spreading more and more; there were 271 cases of cholera, admitted by the official gazette to have occurred between Sept. 26th and Oct. 6th. The daily increase is said to be between thirty and forty cases, with a mortality of 40 per cent. More than 100 patients are now under treatment at the cholera barracks. Most of the cases occurred near the two principal railway stations of the State railway and of the western railway, and this is just the same locality which

formed the principal focus of the cholera epidemic in the year 1886. It is inhabited by poor people, the dwellings being extremely filthy. Now, when it is a little too late, disinfection is being tried, the streets even being moistened by solutions of carbolic acid. The daily papers are marking out now the existence of horrible nuisances, but in the meantime the disease has been conveyed to other Hungarian towns, and the outbreak of the cholera epidemic had to be reported this week at Szegedin, a town which was also infected from Budapest in the year 1886. The number of physicians at Budapest has proved so insufficient that medical students had to be engaged at the hospitals. The schools are now closed and a great number of persons have left the town. The Austrian Government has ordered a careful medical inspection of passengers and their luggage arriving in Austria from Hungary, and the importation of most of the articles from the same country is prohibited. At Vienna the mortality has been extremely low during the last few weeks, not exceeding 19 per 1000, while it is 23·0 per 1000 generally; but it seems that cases of a disease bearing an influenza-like character have occurred more frequently during the last few weeks.

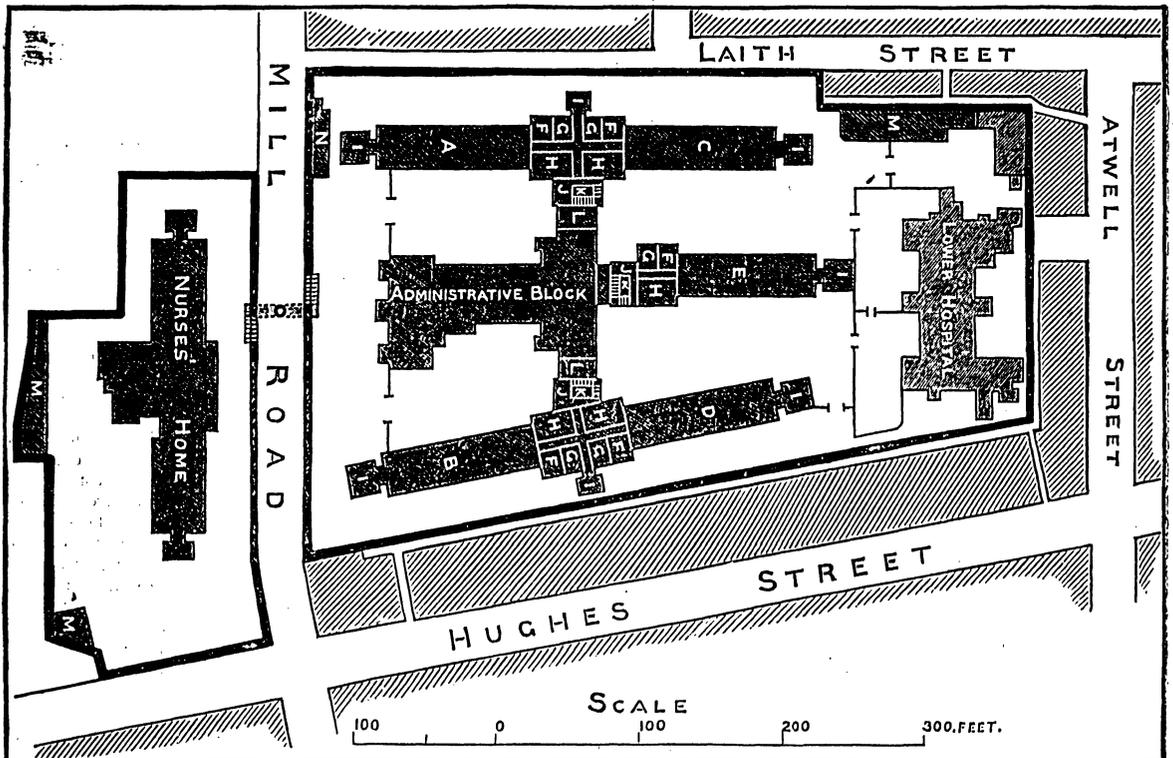

THE NEW HOSPITAL FOR THE WEST DERBY UNION.

By W. FINGLAND, L.R.C.P. & S. EDIN., MEMBER OF THE COMMITTEE OF MANAGEMENT.

It has occurred to me that a brief description of this extensive hospital, now approaching completion, would not be devoid of interest to the profession generally. First, to recognise the desire of the West Derby guardians to provide efficient modern hospital accommodation for their sick poor; secondly, as a record of the progress of hospital construction and arrangement; and, thirdly, to set forth the value of appointments connected therewith to junior members of the profession, where the opportunities for extending their practical knowledge of medical and surgical cases are virtually unlimited. The West Derby Union is one of the largest in the kingdom, both as regards area and population. It includes under its administration a large part of the city of Liverpool. The new hospital is centrally situated as regards the most

populous part of the Union, and occupies the site which was covered by a former hospital built in the early part of this century. This site has, however, been recently much extended by the absorption of a quantity of small property in its immediate neighbourhood.

The hospital is built of grey and red brick with terra-cotta and sandstone dressings. The administrative block, the only one in which any decorative effect has been introduced, is principally enriched with terra-cotta and has a projecting porch of red sandstone. It is designed in the Elizabethan style, and presents a pleasing and imposing appearance. The ground plan of the hospital may be represented by a double H, thus: [—|—], and consists of five ward blocks, the central anterior limb being the administrative block. The administrative block consists of four storeys, including the basement. The basement contains porter's room and dormitory, bath-room and lavatory, mess-room, also convenient and well arranged store-rooms for drugs, wine and beer, groceries, potatoes, meat &c. Access is also provided to receptacles, external and on each side of the building, for coal, coke, wood and potatoes. Two huge boilers are placed here to supply the hot water to the duty rooms, lavatories and to the coils of pipes to be placed in the corridors of the

hospital and Nurses' Home. On the ground floor are offices and sitting-rooms for the medical superintendent and assistants, steward and matron, dispensary, committee-room, kitchen, pantries and lavatory. On the first floor there are bedrooms and bath-rooms for the medical staff and matron, together with linen and sewing-rooms. On the second floor there is bedroom and bath-room accommodation for the house servants of the staff. Between the administrative block and the ward block immediately behind is a large and lofty kitchen, the walls of which are built of white glazed brick with dado. It is lighted from the roof, and conveniently situated to the adjacent hydraulic lifts which convey the diets to each ward. On each side, and forming a part of the transverse portion of the plan, are the male and female receiving-rooms, with bath-rooms attached thereto. Close to these are the lifts for the patients, three in number.

On each side the transverse part of the hospital is converted into a spacious balcony, where the patients who are well enough to leave the wards can enjoy the fresh air. This balcony is in two tiers, cleverly constructed on iron pillars and girders and communicates with the third and fourth floors of each ward block. As mentioned above, there are five distinct blocks of wards, each of which has four floors, including the basement (and it will be necessary here to explain that by "basement" a low dark cellar is not to be inferred); whereas the wards in the basement do not differ in any respect from those overhead, they are identical in every particular excepting in height, the ceilings being 3 ft. lower. They are surrounded by a spacious area, portions of which will be covered with glass, forming a useful and agreeable promenade. Moreover, from the contour of the site the basements of the front blocks may be almost considered as ground floors. It is not, however, intended to make use of the basements excepting when the resources of the hospital are unusually heavily taxed. There are therefore twenty wards, sixteen of which are 108 ft. by 24 ft. and 14 ft. in height, containing thirty-six beds each. The remaining four wards are in the block to the rear of the administrative block and measure 96 ft. by 24 ft. and 14 ft. high, containing thirty-two beds each. To every ward is annexed a small isolation ward for two beds. To these must be added the lunacy annexe, which is situated at the rear and transversely to the main building, containing 150 beds, but is not modern, making a grand total of 1000 beds. As the wards and their adnexa are precisely similar to each other, one description will suffice for them all. The floor is of pine blocks laid in asphalt on concrete. The margin is finished off with an oak fillet to prevent the accumulation and facilitate the removal of dust. The cornice is covered for a similar reason. Each ward is heated by two stoves centrally placed; the flues are deflected and carried up the outside walls of the building. At the base of each are fitted iron soot-doors for cleaning and examination.

The wards are lighted by windows which have an east and west aspect respectively. The upper sashes are of light iron work, the inferior half opening inwards. The ventilation is further carried on by ventilators placed under each window, which may be opened or closed as desired. Also by ventilators placed in the walls immediately below the ceiling, which communicate with shafts contained in brick pillars in the external walls, and are carried up directly to patent extractors fixed in the roof. The fanlights of the doors are similar to the windows. In the top floors the last-named ventilators are fixed in the ceilings. The wards are fitted with gas brackets placed on the walls only, the gas pipes being visible and not buried in the plaster. This remark also applies to the water pipes. At the proximal end of each ward there is a day-room, a separation ward for two beds, a duty room fitted with a convenient kitchen range, together with a sink with hot and cold water. These apartments are ventilated similarly to the wards. Two linen closets are also adjacent to the wards. At the distal end of each ward and forming a kind of annexe is placed a fire-escape staircase built of stone; bath-room, water-closets with overhead cisterns; and sink with double-way flush. These offices are all separate. The walls are lined with glazed brick in two colours with dado. The hot-water pipes are of copper, on account of its greater durability and less expansibility. The cold-water pipes are of lead. The corridors are covered with blue-and-red tiles laid on concrete. Those on the ground floor are covered with glass, in order to admit additional light to the corridors in the basement.

On the opposite side of the road on which the hospital is situated and connected with it by means of a capacious sub-

way lined with white glazed brick is the Nurses' Home. This building corresponds in style and treatment to the hospital opposite. It is built in three storeys and has an extensive frontage. On the ground floor are dining-room, sitting-rooms, kitchen, linen and store rooms, also a lofty apartment lighted from the roof, which may be used equally well as a chapel or a recreation hall. On this and the first floor there are sixty-three bedrooms for the nursing staff, together with well appointed rooms and lavatory accommodation for the lady-superintendent and her assistants. There is also accommodation for sick nurses, and the third floor contains bedrooms for the house servants. A suitable lodge is placed at the entrance gates to the hospital. A large piece of land has also been acquired adjoining the Nurses' Home on which it is intended to erect a suitable residence for the medical superintendent. This will add greatly to the completeness and symmetry of the establishment. The extensive arrangements connected with the successful progress and culmination of the scheme were carried out by Mr. H. P. Cleaver, the clerk to the union. The architect is Mr. Charles Lancaster and the contractor Mr. E. Gabbutt.

## THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of the Association of Fellows of the Royal College of Surgeons of England was held on Wednesday, Oct. 12th, at the residence of the President (Mr. George Pollock), 36, Grosvenor-street, W. There was a large attendance.

The minutes of the last meeting were read by the honorary secretary (Mr. H. Percy Dunn), and, after some discussion, were held over till the next meeting for confirmation. Letters of regret at being unable to attend were read from, Dr. W. J. Collins, Dr. George Helm of Truro and Mr. George Jackson of Plymouth.

The honorary Secretary presented a printer's account for the issue of the recent report of further proceedings of the Association of Fellows, copies of which were forwarded to Fellows of the College whose addresses were known. This account amounted to £12 8s. 6d., and was handed to the treasurer for payment.

The committee then adjourned.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*Enteric Fever in the Ashby Wolds Urban District.* By Dr. F. PARSONS.—An interesting account is briefly given by Dr. Parsons of an outbreak of enteric fever at Newfield, Moira, in this urban district. Nineteen cases and five deaths of the disease occurred last year, and the circumstances leading to its diffusion are carefully discussed. On the whole Dr. Parsons is inclined to believe that the propagation of the fever took place as the result of structural sanitary defects. He draws especial attention to one wash-house used in common by the whole of the row of cottages on which the incidence of the disease particularly fell, and in which the soiled linen of the first patient was washed. In this locality the yard surface was in part unpaved, it was ill-kept, and there was a deficient water-supply. With a mining class, bad sanitary conditions, and the existence of infectious excreta, it is by no means difficult to think of a number of ways in which air and soil, if not water, might become a means for conveying the contagium of enteric fever. Amongst the urgent wants of the place is an adequate supply of wholesome water.

*Enteric Fever and Diphtheria in the Ashby-do-la-Zouch*

1 Eyre and Spottiswoode, East Harding-street, E.C.; John Menzies and Co., Edinburgh and Glasgow; Hodges, Figgis and Co., Dublin; Price 4d.

*Rural District.* By Dr. F. PARSONS.—From an administrative point of view and for local purposes this report is distinctly a valuable one; from an etiological point of view it simply tells the old story of excremental filth in air and water, and of a considerable amount of preventable disease. Coal-ville is the place that mainly suffered, and whether its dirty midden privies, its bad scavenging, its leaky drain pipes and "sumps," or its defective water-supply be considered, the story is one of bad administration and of neglect. The report contains no recommendations, but anyone reading between the lines can see what is wanted, and it is to be hoped that at a season like this when such nuisances are likely to be of special danger, local as well as national, that every pressure will be put upon the local authority to mend their ways on modern and scientific public health lines.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Salford Urban District.*—Mr. Charles Paget's report on this important district for the year 1891 forms one of a long series of very excellent reports issued from the health department of the borough. The annual death-rate was 26.0 per 1000, which is not a low one for English boroughs, but steady improvement is in progress with a view to its diminution, and amongst the latest instances is the opening of an admirable hospital for infectious diseases. The zymotic rate is one which has already commenced to diminish, and it bids fair to continue on its downward course. The inspectorial staff has been increased, the sanitary work has been on a larger scale than formerly, and cellar dwellings have been reduced in number; but other improvements are needed, notably some proper way for disposing of the excess of refuse and the erection of public abattoirs. Mr. Paget points out anew the statistical errors which are inseparable from our system of taking the census only once in every ten years, and urges the necessity for a quinquennial enumeration of the people.

*Kingston-upon-Hull Urban District.*—The revised population for Hull was 200,934 in 1891, and on this the general death-rate was 20.5 per 1000, the zymotic rate being 1.7. This latter rate was largely due to deaths from measles and diarrhoea. The isolation hospitals received 168 patients, and Dr. Mason, in speaking of this work, says that it cannot be overestimated. A steady house-to-house visitation was maintained during the year, 4239 houses having been examined in detail. So also 1709 visits were paid by day and night to the common lodging-houses, and other establishments, including bakeries &c., were visited in like proportion. It is steady work of this character that is, above all things, valuable. It leads to the detection and remedy of multitudinous conditions that would otherwise escape observation, and which, if not dealt with in advance, would tend to the spread of imported preventable disease and to a wasteful because hasty expenditure. The closet accommodation is kept under watchful supervision and such excreta and refuse as cannot be utilised for manurial purposes are dealt with in a destructor. Dr. Mason illustrates his report by diagrams and tables which add much to its value.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6132 births and 3470 deaths were registered during the week ending Oct. 8th. The annual rate of mortality in these towns, which had declined from 19.8 to 16.6 per 1000 in the preceding five weeks, rose again last week to 17.8. In London the rate was 16.4 per 1000, while it averaged 18.7 in the thirty-two provincial towns. The lowest rates in these towns were 10.3 in Croydon, 11.9 in Blackburn, 12.7 in Leicester, and 13.0 in Derby; the highest rates were 22.0 in Liverpool, 22.5 in Preston, 23.3 in Bolton, and 26.7 in Salford. The 3470 deaths included 505 which were referred to the principal zymotic diseases, against numbers declining from 989 to 535 in the preceding five weeks; of these, 206 resulted from diarrhoea, 73 from diphtheria, 70 from measles, 68 from scarlet fever, 45 from "fever" (principally enteric), 43 from whooping-cough, and not one from small-pox. No fatal case of any of these diseases occurred last week in Halifax; in the other towns they caused the lowest death-rates in Derby, Bristol, Birkenhead, and Blackburn; and the highest rates in Swansea, Hull, Leeds, Preston, and Salford. The greatest mortality from measles occurred in

Huddersfield, West Ham, and Salford; from scarlet fever in Plymouth and Preston; from whooping-cough in Huddersfield and Salford; from "fever" in Portsmouth, Leeds, and Swansea; and from diarrhoea in Bolton, Cardiff, Leeds, Nottingham, Hull, and Preston. The 73 deaths from diphtheria included 51 in London, 4 in Croydon, and 4 in Sheffield. No fatal case of small-pox was registered either in London or in any other of the thirty-three large towns; three cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 6 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3628, against numbers increasing from 3052 to 3514 on the preceding seven Saturdays; 412 new cases were admitted during the week, against 370 and 369 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 114 to 171 in the preceding five weeks, further rose to 184 last week, but were 53 below the average. The causes of 78, or 2.3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Oldham, Newcastle-upon-Tyne, and in six other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Blackburn, and Gateshead.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17.9 and 17.1 per 1000 in the preceding two weeks, rose again to 18.5 during the week ending Oct. 8th, and exceeded by 0.7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11.5 in Paisley and 11.6 in Greenock to 19.8 in Edinburgh and 20.6 in Perth. The 515 deaths in these towns included 22 which were referred to diarrhoea, 22 to measles, 16 to scarlet fever, 8 to whooping-cough, 6 to diphtheria, 3 to "fever," and not one to small-pox. In all, 78 deaths resulted from these principal zymotic diseases, against 77 and 84 in the preceding two weeks. These 78 deaths were equal to an annual rate of 2.8 per 1000, which was slightly above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhoea, which had been 27 and 24 in the preceding two weeks, further declined to 23 last week, of which 13 occurred in Glasgow and 5 in Dundee. The deaths referred to measles, which had been 12 and 18 in the preceding two weeks, further rose to 22 last week, and included 17 in Edinburgh and 2 in Leith. The fatal cases of scarlet fever, which had risen from 10 to 17 in the previous three weeks, were 16 last week, of which 11 occurred in Glasgow, 2 in Edinburgh, and 2 in Aberdeen. The 8 deaths from whooping-cough slightly exceeded the number in the preceding week, and included 7 in Glasgow. The 6 fatal cases of diphtheria showed a decline of 4 from the number in the previous week, and included 3 in Glasgow and 3 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 66 and 80 in the preceding two weeks, further rose to 84 last week, but were 5 below the number in the corresponding week of last year. The causes of 54, or more than 10 per cent., of the deaths in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19.7 and 21.5 per 1000 in the preceding two weeks, declined again to 20.0 during the week ending Oct. 8th. During the thirteen weeks of last quarter the death-rate in the city averaged 23.1 per 1000, against 17.1 in London and 16.1 in Edinburgh. The 134 deaths in Dublin during the week under notice showed a decline of 10 from the number in the preceding week, and included 9 which were referred to diarrhoea, 3 to different forms of "fever," and not one either to small-pox, measles, scarlet fever, diphtheria, or whooping-cough. In all, 12 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.8 per 1000, the zymotic death-rate during the same period being 2.0 in London and 5.1 in Edinburgh. The fatal cases of diarrhoea, which had been 15 and 20 in the preceding

two weeks, declined again to 9 last week. The deaths referred to different forms of "fever," which had been 2 in each of the preceding two weeks, rose to 3 last week. The 134 deaths registered in Dublin last week, included 31 of infants under one year of age, and 36 of persons aged upwards of sixty years; the deaths of infants showed a slight increase, while those of elderly persons showed a decline from those recorded in the preceding week. One inquest case and 2 deaths from violence were registered; and 28, or nearly a fourth, of the deaths occurred in public institutions. The causes of 17, or nearly 13 per cent., of the deaths in the city last week were not certified.

## CALCUTTA.

The return of the health officer for Calcutta for the week ending Aug. 20th shows that the total number of deaths registered during the week was 196, against 176 and 189 in the preceding two weeks. There were 2 deaths from cholera, against 8 and 6 in the preceding two weeks. There were no deaths from small-pox. The mortality from fevers and bowel complaints amounted to 68 and 23 respectively. The general death-rate of the week was 21.9 per 1000 per annum, against 20.7, the mean of the last five years. In the amalgamated area of suburbs the total number of deaths registered during the week was 135, against 122 and 105 in the preceding two weeks. There were 3 deaths from cholera, against 5 and 7 during the preceding two weeks; no deaths from small-pox, 16 deaths from tetanus, and the mortality from fevers and bowel complaints amounted to 54 and 22 respectively. The death-rate during the week was 32.7 per 1000 per annum, against 47.7, the mean of the last three years. The general death-rate of the combined area was equal to 25.3 per 1000.

## VITAL STATISTICS OF LONDON DURING SEPTEMBER, 1892.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during the month of September in each of the forty-one sanitary districts of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the accompanying table was equal to 17.4 per 1000 of the population, estimated at 4,263,294 persons in the middle of this year. Owing to the increasing prevalence of scarlet fever and of diphtheria in London this rate shows a marked further increase upon those recorded in the preceding seven months, which had steadily risen from 5.1 to 12.5 per 1000. Among the various sanitary districts the rates last month were considerably below the average in Paddington, Kensington, Fulham, Westminster, St. Martin-in-the-Fields, St. Saviour Southwark, and Lewisham (excluding Penge); while they showed the largest excess in Hackney, Strand, Holborn, all the districts of East London, and in Bermondsey. The prevalence of small-pox in London showed a further decline during September, only 3 cases being notified during the whole month, or less than an average of 1 per week, while the weekly average of cases during the preceding four months had been 27, 16, 5 and 4 respectively; of the 3 cases notified last month 1 belonged to Kensington, 1 to Bethnal Green and 1 to Poplar. The Metropolitan Asylum Hospitals and the Highgate Small-pox Hospital contained 8 small-pox patients at the end of September, against 108, 40, 9 and 8 at the end of the preceding four months; the weekly admissions averaged 2, against 29, 11, 5 and 2 during the previous four months. The prevalence of scarlet fever in London during September showed a further marked increase upon that recorded in recent months; this disease was proportionally most prevalent in Hackney, Strand, Holborn, Shoreditch, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, Newington, Bermondsey, Camberwell and Plumstead sanitary districts. The Metropolitan Asylum Hospitals contained 3407 scarlet fever patients at the end of September, against numbers increasing from 1142 to 3213 at the end of the preceding seven months; the weekly admissions averaged 355, against 238, 335 and 378 in the preceding three months. Diphtheria showed the highest proportional prevalence during September in Hammersmith, in Westminster, in all the districts of East London, in Battersea and in Lewisham. There were 318 cases of diphtheria under treatment in the Metropolitan Asylum Hospitals at the end of September, against numbers steadily increasing from 198 to

310 at the end of the preceding six months; the weekly admissions averaged 54, against 56 and 55 in the preceding two months. Enteric fever was proportionally most prevalent in St. George Hanover-square, Islington, St. George-in-the-East, Poplar and Greenwich sanitary districts. The Metropolitan Asylum Hospitals contained 113 enteric fever patients at the end of September, against numbers increasing from 47 to 93 at the end of the preceding four months; the weekly admissions averaged 20, against 16 and 14 in the preceding two months. Erysipelas showed the highest proportional prevalence during the month under notice in St. Giles, Holborn, St. Luke, Bethnal Green, Whitechapel and Bermondsey. Five cases of puerperal fever were notified during September in St. Pancras and 4 in Whitechapel sanitary districts.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary districts, the deaths occurring in the institutions of London having been distributed among the various sanitary districts in which the patients had previously resided. The distribution of these deaths, and especially of those resulting from zymotic diseases, affords the most trustworthy data that can be secured upon which to calculate reliable rates of mortality. During the four weeks ending on Saturday, Oct. 1st, the deaths of 5144 persons belonging to London were registered, equal to an annual rate of 15.7 per 1000, against 17.8 and 16.9 in the preceding two months. The lowest death-rates during September in the various sanitary districts were 8.9 in Hampstead, 9.6 in St. James Westminster, 10.3 in Lewisham (excluding Penge), 11.3 in Wandsworth, 11.4 in St. George Hanover-square, 11.6 in Paddington, and 11.9 in Kensington; in the other sanitary districts the rates ranged upwards to 21.6 in Whitechapel, 22.3 in Clerkenwell, 22.7 in St. Luke and in St. Saviour Southwark, 23.4 in City of London, 23.9 in St. Martin-in-the-Fields, and 27.9 in St. George-in-the-East. During the four weeks of September 838 deaths were referred to the principal zymotic diseases in London; of these, 394 resulted from diarrhoea, 165 from diphtheria, 123 from scarlet fever, 62 from different forms of "fever" (including 60 from enteric fever, 1 from typhus fever and 1 from an ill-defined fever), 55 from measles, 39 from whooping-cough, and not one from small-pox. These 838 deaths were equal to an annual rate of 2.6 per 1000, against 3.1, 3.9 and 3.4 in the preceding three months. Among the various sanitary districts the lowest zymotic death-rates were recorded in Hammersmith, St. George Hanover-square, St. James Westminster, Hampstead, St. Martin-in-the-Fields and Strand; and the highest rates in Clerkenwell, Bethnal Green, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, Newington and St. Olave Southwark. The 55 deaths referred to measles were 25 below the corrected average number in the corresponding month of the preceding ten years; this disease showed no marked fatality last month in any of the sanitary districts. The 123 deaths from scarlet fever were 11 above the corrected average; among the various sanitary districts this disease showed the highest proportional fatality in St. George-in-the-East, Limehouse, Mile End Old Town, Poplar and Bermondsey. The 165 fatal cases of diphtheria exceeded by 67 the corrected average; this disease showed the highest proportional fatality in St. Pancras, Hackney, Bethnal Green, Mile End Old Town, Poplar, Newington and Plumstead. The 39 deaths referred to whooping-cough were less than a third of the corrected average number; this disease showed no marked fatality in any of the sanitary districts. The 62 deaths referred to different forms of "fever" were 14 above the corrected average; there was no marked excess of fever mortality in any of the sanitary districts during the month under notice. The 394 fatal cases of diarrhoea exceeded by 20 the corrected average; this disease was proportionally most fatal in St. Giles, Bethnal Green, St. George-in-the-East, Limehouse, St. Saviour Southwark, and Rotherhithe. In conclusion, it may be stated that the mortality in London during September from these principal zymotic diseases was 4 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 149 per 1000 during September, and almost corresponded with the average; the lowest rates of infant mortality were recorded in St. James Westminster, Marylebone, Hampstead, St. Giles, St. George Southwark and Rotherhithe; the highest rates in Kensington, Westminster, St. Martin-in-the-Fields, City of London, Whitechapel, St. George-in-the-East and Limehouse.

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON.—SEPTEMBER, 1892.  
(Specially compiled for THE LANCET.)

Sanitary areas.	Estimated population in the middle of 1892.	NOTIFIED CASES OF INFECTIOUS DISEASE.										DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.										Annual rate per 1000 persons living.	Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.		
		Small-pox.	Scarlet fever.	Diphtheria.	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Krysipelas.	Membranous croup.	Cholera.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.					Diarrhoea.	Total.

## THE SERVICES.

## MOVEMENTS OF MEDICAL STAFF.

Surgeon-Lieutenant-Colonel Finlay has taken up duty at Hounslow. Brigade-Surgeon Gillespie, retired pay, has resigned the medical charge at Galway. Surgeon-Major Macnamara has rejoined at Portsmouth. Surgeon-Captain Leishman has obtained leave from Bombay on medical certificate. Surgeon-Captain Lambkin has embarked for Jamaica on a tour of foreign service. Surgeon-Captain A. Morris has been transferred from Ireland to Netley. Surgeon-Captain Stanistreet has taken up duty at Canterbury. Surgeon-Lieutenant Buchanan has been transferred to Pontefract. Surgeon-Major W. Venour (retired pay) has been taken on the strength of the district and posted to Penally for duty. Surgeon-Captain Hickson has been transferred from Templemore to the Royal Infirmary, Dublin, for duty. Surgeon-Lieutenant H. A. Stalkart has been transferred to the Curragh for duty.

## INDIAN MEDICAL SERVICE.

Surgeon-Captain J. Murray, I.M.S., Bengal Establishment, has been appointed Professor in the Lahore Medical College from May 24th, 1892. Surgeon-Lieutenant-Colonel Hughes, Civil Surgeon, Poona, has been ordered to Bombay to take over the duties of Principal Medical Officer of the Bombay, Aden and Deesa Districts from Surgeon-Colonel Cates, vacating on the 15th inst. on retirement. Surgeon-Major J. E. Ferguson, M.B., I.M.S., has been granted extension of leave to six months on medical certificate. Surgeon-Lieutenant-Colonel H. Stannard, Medical Staff, remains at home on extended leave.

## NAVAL MEDICAL SERVICE.

The following appointments have been made:—Staff Surgeons: Joseph Cowley, M.D., to the *Scout* (undated); Charles A. Macaulay to the *Castor* (dated Sept. 30th, 1892); John J. Dinnis, M.D., to the *Phaeton*, reappointed (dated Oct. 2nd, 1892). Surgeons: James M. France to the *President*, additional (dated Oct. 11th, 1892); John H. Thomas to the *Bellerophon*, John L. Barrington to the *Melita*, and T. P. J. Coolicon to the *Ruby* (all dated Oct. 1st, 1892); Frederick J. Burns, M.D., to the *Belleisle*; and D'Arcy Harvey to the *Vernon*, additional, for disposal, and Clement Alsop to the *Melita* (both dated Oct. 11th, 1892). Surgeons and Agents: Henry M. Scott at Inniscrone and Pullocheny, and John J. McNulty at Derkinore and Pullendiva (both dated Oct. 5th, 1892).

## VOLUNTEER CORPS.

*Artillery*: 4th Lancashire: Surgeon-Captain T. F. Young to be Surgeon-Major (dated Oct. 8th, 1892).—*Royal Engineers* (Fortress and Railway Forces): 1st Flint (Buckley): Surgeon-Lieutenant J. Williams resigns his commission (dated Oct. 8th, 1892).—*Rifle*: 1st Volunteer Battalion, the Princess of Wales's Own (Yorkshire Regiment): Surgeon-Lieutenant A. Barber, M.B., resigns his commission (dated Oct. 8th, 1892).—1st (Hallamshire) Volunteer Battalion, the York and Lancaster Regiment: Henry Temple Wightman, Gent., to be Surgeon-Lieutenant (dated Oct. 8th, 1892).—1st (Invernesshire Highland) Volunteer Battalion, the Queen's Own Cameron Highlanders: John Macdonald, M.B., to be Surgeon-Lieutenant (dated Oct. 8th, 1892).

## AN EARLY RATION FOR SOLDIERS.

OUR attention has been called by a military officer of rank and experience to the desirability of providing the soldier with an early ration before his morning drill. There is no doubt that an issue of this kind would be beneficial to the health of our young soldiers and would tend to promote contentment and sobriety and, as a consequence, discipline in the ranks. The great defect at present in the dieting of soldiers is in regard to the supper and breakfast meals. There is no doubt that much has been done of late, as we have already pointed out, in the way of the improved character of the rations and in their cooking. It should be practicable to make some regimental arrangements for providing the soldier with a cup of tea or coffee, with bread, before early parade, and we believe that this is already done in many corps. Facilities should also be offered to a soldier for cooking in military cook-houses certain articles of diet which he purchases at the canteen for his breakfast.

## THE BERLIN-VIENNA MILITARY RIDE.

As far as any practical purpose goes the late military ride, to which we alluded last week, has been a futile undertaking, and a very cruel one as far as the unfortunate

horses were concerned. A considerable number of the animals have died in consequence of the fatigue and hardship they have undergone. It has served to show, perhaps, that the Hungarian horses have endurance or "staying power," but this was pretty well known beforehand. It is stated that most of the winners declare that they will never take part in such a ride again, and that long-distance rides must in future be undertaken under very different conditions. To force on horses in the last stage of their journey when they are nearly dead with fatigue, unless under the most urgent and exceptional circumstances, seems to us to be quite unjustifiable, and we are glad that there does not seem to be a prospect of any similar rides being undertaken in future. It was altogether ignoble and demoralising exhibition.

## A DEATH RECORD.

Disease of a fatal kind has been very prevalent of late among British officers in India. Surgeon-Colonel A. Allan, Army Medical Staff, and Surgeon-Captain M. Fowler, Army Medical Staff, as was announced in our last issue, recently died of cholera at Murree, and the death of Surgeon-Captain H. N. Kenny on the 4th ult. had been previously reported; the deaths of four other officers belonging to different branches of the service have also been recorded from cholera or enteric fever. As regards the occurrence of the cases of cholera at Murree, it was attributed by some to the recent importation of the disease into that station and by others to the use of contaminated water for making soda water.

## THE LATE SURGEON-GENERAL R. C. ELLIOTT, C.B. (RETIRED).

We regret to announce the death of this officer at Devonport on the 6th inst., aged seventy-five years. He joined the Army Medical Department June 7th, 1839, went through the different steps of rank until he reached that of Surgeon-General in February, 1876, and retired from the service on June 28th of the same year. He served throughout the Eastern campaign of 1854-6, including the affairs of Burganac and M'Kenzie's farm, battles of Alma, Balaclava and Inkerman and siege and fall of Sebastopol. After promotion to the post of Senior Surgeon to the Royal Artillery he was appointed Superintendent-Surgeon to the whole of the ordnance corps in the Crimea (medal with four clasps, Knight of the Legion of Honour, 5th Class of the Medjidie and Turkish medal; thrice mentioned in despatches); served during the Indian Mutiny, 1857-9, and was present at the action of Pandoo-Nuddee, operations before Cawnpore, Nov. 27th, 28th and 29th, under General Windham, and battle of Cawnpore, Dec. 6th (mentioned in despatches; medal).

## DEATH OF SURGEON-GENERAL J. P. CUNNINGHAM, M.D. (RETIRED).

We regret to announce that this officer of the Army Medical Department died at Bedford, on Sept. 30th, aged sixty-five years. He joined the army in April, 1852, became Surgeon in March, 1859, Surgeon-Major in 1872, Brigade-Surgeon in 1879 and Deputy Surgeon-General in 1880, and retired with the honorary rank of Surgeon-General in 1882. He served as a Surgeon of the 60th Rifles, and subsequently of the 20th Hussars in India.

## THE CLOSE OF THE BLACK MOUNTAIN EXPEDITION.

We had scarcely announced the fact of the commencement of another Black Mountain Expedition before a telegram was received in this country from the Viceroy of India informing us of its close. The little war is over and the troops have returned to their quarters after destroying Baio. It is stated, but we can hardly believe it, that no field hospital accompanied the force. The questions call for answer, What was to have become of the sick and wounded in the event of there having been any and how were they to be treated? The public is getting rather weary of these small wars and expeditions in India. They seem to be undertaken without a sufficiently definite and practicable object in view; they are, too, very costly, and the Indian Exchequer is not in a position to afford any increased military expenditure. The wisdom of such a policy is not, we must say, very apparent to outsiders. The appearance of our troops simply causes the tribes to scatter and disappear until they are withdrawn. We have in the present instance destroyed some forts which Hashim Ali and his tribes will build up again and wait for the appearance of another English force.

## SIKQ QUARTERS IN INDIA.

We notice that attention has been called to the regulations affecting officers on the sick list in India by which they are

confined to their quarters and prohibited from attending mess or going to any public gathering or places of amusement. We quite concur, of course, in thinking that an officer recovering from illness or convalescing requires a certain amount of air and exercise and some companionship and change of scene, and that anything in the way of vexatious regulations in these respects should be removed; but we believe that, after all, his case is not quite so hard as represented, for he can always obtain official sanction, on the recommendation of the medical officer, to taking air and exercise or going for a ride with or without a companion, or doing anything reasonable, in short, towards the restoration of his health, except going to mess or public amusements; and we do not imagine that any officer commanding the station or district would prohibit his going to hear a regimental band or to the mess ante-room to read the papers if permission to do so were asked by the medical officer in attendance.

#### THE ACCOMMODATION OF TROOPS IN THE CHIN HILLS.

Sanction has been given for the immediate construction of barracks and huts at different stations in the Chin Hills for the accommodation of upwards of 1000 men.

#### THE PARKES MEMORIAL GOLD MEDAL.

Surgeon-Captain R. H. Firth, whom we recently congratulated on his appointment to Netley as Assistant Professor of Military Hygiene, has won the Parkes Memorial Gold Medal for 1892. This officer gained the same honour in 1889, and he also won the Alexander Medal in 1888 and 1891 respectively.

## Correspondence.

"Audi alteram partem."

### THE DEBATE ON "VIVISECTION" AT THE RECENT CHURCH CONGRESS.

To the Editors of THE LANCET.

SIRS,—The debate on the vivisection question at Folkestone last Thursday was unfortunately curtailed, but perhaps enough transpired during the discussion to show the true relation which exists between the clergy (I will not say the Church) and the medical profession on this vexed matter. I had hoped to be present and to address a few remarks to the meeting. I now beg leave to offer in your columns the gist of my opinions, and, for the sake of brevity, I will state them categorically as follows: 1. That the very great majority of thoughtful and prudent members of the medical profession fully recognise the value of the services which have been, and are constantly being, rendered to humanity by researches involving experimentation upon living animals, such services distinctly aiding them daily in improving their methods of treating disease, in relieving suffering and in saving human as well as other lives. 2. That the objections commonly made to this practice, as now carried on in Great Britain, are quite unwarrantable, and result from prejudice and culpable ignorance on the part of those who publicly make them. 3. That a Church Congress is a most unfit body to discuss any such question, inasmuch as it must necessarily and mainly consist of persons who are quite unfit to form trustworthy opinions on the matter. 4. That if the whole body of Anglican bishops or of any other bishops, and all the dignitaries of the Church, with the added weight of a large Church Congress, were to pronounce against the practice of experimentation upon living animals, we of the medical profession would pay no heed to any such verdict, and would continue, as we judged best, to prosecute such researches without any misgivings or qualms of conscience. 5. That members of the medical profession have now, as they have always had from the time of St. Luke, as delicate and refined a moral sense as that possessed by any body of ecclesiastics, and have nothing to learn in such respect from the latter. 6. That persons who make public charges of inhumanity and cruelty against medical experimentalists, be they bishops, statesmen, or irresponsible women, simply deserve pity, and they are unworthy of the attention of right-minded men, inasmuch as their views are the outcome either of a distempered brain or of a wilfully distorted judgment.

As a Churchman, I consider the authorities of the Congress

to have made a grievous mistake in sanctioning the reading of Bishop Barry's paper, and that its delivery constituted a lamentable blot on the proceedings of what was otherwise a very brilliant meeting, redounding much to the honour and credit of the great Anglican Communion.

I am, Sirs, yours truly,

DXCE DUCKWORTH, M.D., LL.D.,  
President of the Clinical Society of London.

Grafton-street, W., Oct. 8th, 1892.

To the Editors of THE LANCET.

SIRS,—I had intended to speak last Thursday at the meeting for the discussion on vivisection during the Church Congress, and had sent in my name to the Archbishop for that purpose, but so much time was wasted at the commencement of the proceedings that none was left for myself and other speakers. I had intended to say that, with the greatest respect for the Church Congress, its objects and its members, I yet did not consider it a fit or proper tribunal before which to discuss so technical a question as vivisection, a subject which very few of those present were capable of either understanding or appreciating. In proof of this assertion, I may instance that one reader introduced the subject of the Hyderabad Chloroform Commission and raised the question as to whether death from chloroform resulted primarily from failure of the cardiac or respiratory centres. Scarcely, Sirs, a question for such a meeting to deal with. Pasteur's anti-rabic injections were ridiculed and deprecated by one reader, defended and commended by another. Are these questions for clergymen and ladies to decide? Are they not better left to those who are really practically conversant with the subjects? For these reasons I should have declined to discuss the morality of vivisection before such an audience, as I consider it would have been derogatory to the dignity of our profession; at the same time I meant to have pointed out that every administration of a new drug (however valuable it might afterwards prove to be) was essentially "an experiment on living animals," and yet I suppose there are few of even the most rabid anti-vivisectionists who would not prefer to have that drug previously tested on one of the lower animals rather than on themselves.

I was agreeably surprised to note the distinctly sympathetic tone manifested by the meeting for the scientists, the marked approval with which Mr. Victor Horsley's powerful address was received and the ill-concealed impatience with which some most unworthy utterances on the other side were listened to, all which showed that the clergy of to-day are resolved not to identify themselves with the cause of scientific obstruction. Surely the medical profession is the best, the only judge, of the necessity—the painful necessity, if you will—of experiments on living animals, and the public, who trust us with all else, their lives, their health, their honour, will trust us in this matter also, remembering that doctors are not only honourable gentlemen, but of all men the most compassionate.—I am, Sirs, yours truly,

CH. EGERTON FITZGERALD, M.D.

Folkestone, Oct. 10th, 1892.

### PHTHISIS IN EGYPT.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you will allow me a small space in your columns to make some remarks on the very valuable contribution of Dr. Sandwith to the natural history of phthisis, which appeared in THE LANCET of Sept. 24th. Although I have not had the extensive experience of Dr. Sandwith, I paid considerable attention to this subject during a residence of four years in Egypt, having been early struck by the frequency of phthisis among the natives. Dr. Sandwith has collected some valuable data, but I think he does not rightly interpret them. First, as regards the universally admitted high mortality from phthisis among the Soudanese, principally slaves or ex-slaves, I found that about half the deaths of Soudanese in Cairo were from phthisis. Dr. Sandwith attributes this high mortality to their coming to a climate "less hot and less dry than their own," adding that phthisis is rare in the Soudan. The Soudan having a vast and vague extent, it is difficult to speak of its climate, but it seems to me very questionable whether the cultivated parts are on the whole drier than middle Egypt, if they are warmer. And as to phthisis being rare, Pruner distinctly states that it is common among negro captives in Khartoum. I expect we should find, if opportunity allowed, that phthisis is by no means uncommon in any large towns of the Soudan.

On the other hand, while I was Principal Medical Officer of the Egyptian Police I found by carefully kept records that phthisis was no commoner among the Soudanese gendarmerie than it was among the English army of occupation in Egypt; and further, Dr. Sandwith himself states that phthisis is common among white Circassian slaves in Cairo. It is evident, then, that it is not the climate but the conditions of life of the Soudanese in Cairo which must explain their special proneness to phthisis. These conditions are the depressing effects of slavery, confinement, poverty and insufficient food, added to the general insanitary condition of Cairo. Dr. Sandwith shows that phthisis is also common among the native Egyptians, but he does not examine into the causes of this frequency. I found that in 1882-1885 inclusive 8.5 per cent. of the total deaths registered in Cairo were attributed to phthisis, and the death-rate from this disease was 42.5 per 10,000 of population. These figures show that the proportion of deaths from phthisis in Cairo to the whole number of deaths is rather less than in London; but in proportion to the population many more die of phthisis in Cairo than in London. To anyone who knows the insanitary conditions which prevail in the capital of Egypt these results are in no way surprising. There is no drainage, and the soil is waterlogged and saturated with filth. I quite agree with Dr. Sandwith in what he says as to the benefits to be derived from a visit to Egypt, and the great interest the country possesses from an archaeological, ethnological and political point of view will always make it attractive to visitors beyond most health resorts. But I think physicians who are sending patients to Egypt should be warned that they cannot safely reside long in Cairo, but must spend their time at Helouan, the Pyramids, or up the Nile.

I am, Sirs, yours faithfully,

SIDNEY DAVIES, M.A., M.D. Oxon.,

Late Principal Medical Officer, Egyptian Police.

Plumstead, Oct. 4th, 1892.

### "GLYCOSURIA WITH LOW SPECIFIC GRAVITY."

To the Editors of THE LANCET.

SIRS,—The attention directed to the subject of occasional low specific gravity in diabetic urine by Sir E. Sieveking's paper and letters in THE LANCET induces me to state that I published a paper on this subject in the *Dublin Journal of Medicine* in April, 1883. I mention several cases of low specific gravity in this paper; one is that of a patient of the late Dr. Ringland, in which the specific gravity varied from 1008 to 1035. No matter how low the specific gravity was there was a proportionate amount of sugar present. Sir William Stokes had a patient suffering from glycosuria in which I found on several occasions the specific gravity of the urine is very low, and on one occasion actually 1005. Like other medical analysts I come across now and then specimens of urine above 1030 which, though exercising a reducing power on Fehling's solution, contain no sugar.

I am, Sirs, yours truly,

CHARLES A. CAMERON, F.R.C.S.I. &c.

Dublin, Oct. 12th, 1892.

To the Editors of THE LANCET.

SIRS,—The occurrence of sugar in urines of low specific gravity ought to be generally known, as the fact is of fairly common occurrence in hospital practice. In my lectures on diabetes I refer to it (p. 84), and expressly say that a low specific gravity is no proof of the absence of sugar. But the fact is abundantly illustrated by the cases, for out of fifty quoted in the text no less than five, or 10 per cent., had urine of a low specific gravity. These are: Case 14, E. R—, aged thirty-seven; sp. gr. 1020; Case 16, W. F—, aged fifty-seven, sp. gr. 1020; Case 19, E. H—, aged sixty-five, sp. gr. 1013; Case 21, W—, aged fifty-six, sp. gr. 1021; Case 28 A. L—, aged eight, sp. gr. 1013. The last case shows that this may occur even in young persons, though this little girl was a very chronic case, like her sister, whose history is recorded on page 93 (the urine in her case was only 1025). There is only one true method of clinical study, that is to examine each point with the best available means. All short cuts, guesswork, attempts to follow the "method of Zadig," and so forth are untrustworthy, and those who follow them can never hope to increase their own knowledge or that of others.

I am, Sirs, yours obediently,

ROBERT SAUNDBY.

Edmund-street, Birmingham, Oct. 8th, 1892.

To the Editors of THE LANCET.

SIRS,—Not long ago I was called to see a lady who was dying comatose. From the smell I felt that the case was one of diabetes. On examining the urine the specific gravity was under 1020, but there was abundant sugar present. She died in thirty-six hours. I am, Sirs, yours truly,

Oct. 7th, 1892.

E. A. B.

### SALICYLATE OF SODA IN CHOREA.

To the Editors of THE LANCET.

SIRS,—In your issue of July 2nd, under the heading "Notes from a Practitioner's Case-book," Dr. H. H. Murphy records a case of chorea in the adult which was successfully treated with salicylate of soda. In a number of cases of chorea lately under my care the use of this drug has been entirely without beneficial result, and I think the following case is of interest in this connexion.

F. S—, a girl aged seven years, some months ago was seized with a well-marked attack of rheumatic fever, accompanied by endocarditis of the mitral valve. Under salicylate of soda the symptoms rapidly disappeared, as they usually do, and the child became convalescent. Three days afterwards she was regarded as well, and while the salicylate of soda treatment was being continued as a precaution against relapse symptoms of chorea developed, beginning in the left hand and arm, and rapidly spreading so as to involve the whole muscular system. The patient could not sit upright, and had to be restrained in bed. There were also well-marked mental symptoms. Salicylate of soda seemed if anything to increase the disorder, and I then had recourse to arsenic, rapidly increasing the dose until fifty minims of the liquor arsenicalis were taken per diem. This amount was well tolerated. In a few days there was marked improvement, and in four weeks' time no signs of chorea could be detected.

I have mentioned this case because the chorea developed while the patient was under salicylate of sodium, and after this remedy had removed the symptoms of rheumatic fever. It would be interesting to know whether the salicylate treatment of rheumatic fever has had any influence on the number of cases of chorea immediately following the fever. I note that in Dr. Murphy's case arsenic in increasing doses was given. It is not improbable that this drug played a very important part in the successful result, for without doubt arsenic is a most valuable remedy in chorea, especially if pushed to the limits of toleration.

I am, Sirs, yours obediently,

GEO. W. SUTHERLAND, M.D. Lond.

Sydney, Australia, July 23th, 1892.

### REGISTRATION OF MIDWIVES.

To the Editors of THE LANCET.

SIRS,—The letter of Mr. Rowland Humphreys, in your last number on the subject of the ignorance of midwives induces me to send you an account of a case I had last week and which is similar in some of its features to that which he mentions. I was sent for on the 3rd inst. (by a telegram from a village "midwife") to see a woman whom I found in the last stages of exhaustion from post-partum hæmorrhage and who died shortly after my arrival. On making investigations I was informed that the patient had suffered from ante-partum hæmorrhage for some six weeks previously, that she had been confined of her tenth child about three hours before, and that the midwife (who arrived a few minutes after the birth of the child) exerted traction on the cord with the view of removing the placenta. The placenta tore in two with the force used, and the midwife thereupon introduced her fingers into the vagina and tore away the remainder, together with a considerable portion of the uterus, measuring about three inches by two. At the necropsy ordered by the coroner I found a small piece of very firmly adherent placenta near the fundus, and the part where the laceration had occurred was very evident; the serous coat of the organ was intact. The uterine wall was extremely soft and lacerable, and broke down readily on pressure with the finger; the muscular tissue under the microscope showed advanced fatty degeneration. It would seem that, as a consequence of the ante-partum hæmorrhage, the placenta had become adherent to the uterus, and that this, softened by the many and rapidly following pregnancies, had given way under the unskilled violence of the midwife. As in the West Bromwich case, it was allowed

at the inquest that the midwife had done her best according to her lights, but as she had sent for a doctor she escaped censure. I do not know of any recorded case in which this particular accident followed excessive traction on the cord, and should be glad if any of your readers can mention one. I send you a newspaper cutting with a report of the inquest.

I am, Sirs, yours obediently,  
LEWIS E. PARKHURST, M.B. Oxon.

Brackley, Northamptonshire, Oct. 10th, 1892.

## ECCHYMOSES DUE TO NATURAL CAUSES.

To the Editors of THE LANCET.

SIRS,—Your Paris correspondent is right in supposing that the case reported at the Pau Congress of the French Society for the Advancement of the Sciences would be of interest to medical jurists in this country. It is well known already that during the convulsive struggles of the epileptic hæmorrhages may be found beneath the conjunctiva or in the cutaneous tissues about the face, much in the same way as bloody extravasations are found in children suffering from whooping-cough; but few would be prepared to hear of the enormous ecchymoses met with in Dr. Cabadé's carpenter, in whom the convulsion must have been inordinately severe to bring about the startling appearances found on the chest, trunk, shoulders and arms. Such a unique case will tend to emphasise the remarks found in forensic text-books on ecchymoses occurring in the body from natural causes. I am not clear, however, that it is as widely recognised as it ought to be, that the convulsive struggle associated with sudden asphyxia may be the cause not only of punctiform ecchymoses in various parts of the body, but of submucous extravasations, which may give rise to suspicions of foul play. Possibly the mucous surface has not been the subject of as much attention in post-mortem records of suffocation as it deserves. In cases like Dr. Cabadé's, where the external skin showed such extensive evidence of venous pressure from interrupted circulation of the blood from an epileptic fit, it is not unreasonable to believe that the mucous surface more or less shared the damage. In suffocation from the impaction of a foreign body in the windpipe, where the death struggle would be prolonged for four or five minutes, submucous extravasations of blood would in all probability be found in the vaginal mucous membrane and mucous linings of various organs as well as in the serous coverings of the various viscera, and such marks of ecchymosis might readily be attributed to a felonious cause.

I am, Sirs, yours faithfully,

Carlisle, Oct. 12th, 1892. HENRY A. LEDIARD, M.D. Edin.

## NOTIFICATION OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—It is quite unnecessary for me to answer in detail Dr. Goodhart's letter in your last issue, as I find that in a letter from the Local Government Board to the town clerk of Uppingham, under date Dec. 29th, 1890, the following rule is laid down: "If two practitioners are in actual attendance on or are called in to visit a patient, whether at the same period or successively, and their attendance or visiting is connected with the medical treatment of the patient, both are bound to send certificates, and these must be duly paid for by the sanitary authority." As a matter of fact, my authority every month sanctions payments to two or three medical men for certifying a single case, and this in several instances, and the Metropolitan Asylums Board refunds such payments.—I am, Sirs, yours truly,

W. H. CORFIELD, M.A., M.D. Oxon.,

Medical Officer of Health for St. George's, Hanover-square,  
Saville-row, W., Oct. 10th, 1892.

## ENFORCEMENT OF MEDICAL LAW.

To the Editors of THE LANCET.

SIRS,—A query in your issue of Oct. 8th, p. 867, deserves the attention not only of dentists, but of the whole profession. You cite the case of practitioners in Germany who, possessing only the American diploma of doctor of dental surgery, have lately been fined for styling themselves "doctor," it being held that this was calculated to lead the public to mistake

these men for duly qualified doctors of medicine. You suggest the question, Why should not similar abuses be checked here? The evils arising from illegal assumption of professional titles might, there can be no doubt, be very much diminished if any body or functionary existed whose duty it was to enforce the present laws; but in this country no such authority is to be found. Neither the Medical Council, the corporations, nor medical associations take any heed of these matters, and in the absence of a public prosecutor medical law in great measure remains a dead letter. That magistrates are ready to administer the law is evident. The College of Veterinary Surgeons, under the Veterinary Act, the penal clauses of which are the same as those of the Dentists Act, has lately found no difficulty in obtaining convictions for offences in no degree so flagrant as those constantly committed by medical and dental quacks. For merely exhibiting a sign inscribed "Veterinary Smith" an unregistered farrier has been heavily fined within the last few weeks, and it is not credible that magistrates will refuse to apply laws for protection of man whilst enforcing those for protection of beasts.

That quackery outside the profession—practice by unqualified pretenders—does no harm, from the sordid point of view, to the legitimate practitioner in any department is capable of proof. Quackery creates disease and aggravates simple cases, and in the end makes a vast amount of work for legitimate practitioners, into whose hands a large proportion of the victims ultimately gravitate. The injury from quackery falls upon suffering humanity; upon the simple, the confiding and the weak; upon the needy and poor rather than the rich; upon the classes whose claims to protection by the State are paramount. To put the law in force would be to gain the sympathy and support of the public. The profession, if challenged, could demonstrate the purity of its motives. It seems to me time this matter was taken in hand. I would propose the immediate formation of an Association for Enforcement of Medical Law, and in order to bring my proposition to a practical issue I now undertake, if forty-nine other members of the profession will do likewise, to pay in at once to a guarantee fund any sum up to £100 which may be agreed upon by the promoters of such an association, and to contribute besides an annual subscription. If a few examples were made among the quacks it is tolerably certain the need for prosecutions in the future would not often arise; it would be necessary to interfere only with flagrant offenders—if any such exist—not with unqualified individuals who, under no false pretence, may be practising for gain in any department of medicine or surgery.

I am, Sirs, your obedient servant,

Wimpole-street, Oct. 8th, 1892.

HENRY SEWILL.

## "ELECTROPATHIC ADVERTISING."

To the Editors of THE LANCET.

SIRS,—Having returned from my vacation, I find that I am indebted to your courtesy for sending me a copy of your issue of Sept. 24th. In that copy you express "painful surprise" at finding my name "appended to a highly eulogistic letter" addressed to Mr. Harness, and you add that I have "advocated an electropathic appliance, and that you cannot, for the honour of our profession (the italics are mine), refrain from expressing your "strong disapproval of the uses to which I have applied my knowledge." You proceed to say that I have "given warm commendation to a method of treatment closely bound up with quackery." I give a point-blank denial to your assertions. As the author of a standard work upon medical electricity, which you have yourselves approved, it was my undoubted duty to investigate the claims advanced by any inventors of new electrical apparatus claimed to be improvements. In the above capacity I called upon Mr. Harness, telling him that I proposed to investigate the electrical properties claimed by him to be possessed by his apparatus. He courteously supplied me with several varieties, and I have mentioned the results of my experiments with them in the forthcoming new edition of my book. I there state that the only two important questions are: (1) Does the apparatus generate electricity? (2) If generated, does that electricity penetrate the skin? And I add in italics: "These are questions which must be determined, not by the effect of the appliance upon the patient, not by theoretical considerations, but by the test of instruments of precision, and quite irrespective of any claims advanced by the manufacturers or vendors."

As in duty bound, I gave the result of my investigation,

and I wrote a note to Mr. Harness, to which I say that he was thoroughly entitled; but I did not express any opinion as to therapeutic value, as that question did not come within the scope of my investigation.

I notice that a London physician, a general practitioner, a surgeon-general in the army, a navy surgeon, a second general practitioner and another physician, amongst ourselves, to say nothing of continental opinion, speak in terms of praise of the institution; and personally I challenge you to tell me where I could find, at any rate in this country, such perfect static and other machines as those which Mr. Harness possesses and which he advertises are at the service of the medical profession.

I protest against your insinuation that I and of course the medical practitioners I refer to above are insensible to the "honour of our profession." To me such an insinuation is of no moment, as my valued friends will not be influenced by it, but to younger men it might prove of grave import.

I am, Sirs, yours obediently,

HERBERT TIBBITS, M.D., F.R.C.P.E.

Welbeck-street, W., Oct. 11th, 1892.

## THE MEDICAL OFFICERSHIP OF HEALTH OF KINGSTON-ON-THAMES.

To the Editors of THE LANCET.

SIRS.—The Council of the Borough of Kingston-on-Thames have, it appears, received notice from their medical officer of health that he is about to resign his appointment, and they have consequently authorised their clerk to advertise for candidates for the vacancy. The committee, who had originally to consider the matter, came to the conclusion that it would be best to increase the present stipend and appoint a medical man who was not engaged in private practice. But the Council, on hearing the decision, entered on a further discussion, and at last came to the conclusion that as they had a good inspector of nuisances the medical officer of health would have but little to do, and they might therefore very well reduce the present salary. Now, with all due deference to this authority, I venture to say that the sanitary condition of Kingston-on-Thames is far worse than they appear to imagine, and the medical officer of health, if he is determined to bring to light and correct all sanitary defects, will have his time more than closely occupied. However, should the Council, in spite of the advice tendered, determine to adhere to their decision, it would surely be advisable for them to make the election an annual one till some scheme for consolidating the various health appointments were agreed upon.

I am, Sirs, your obedient servant,

SANITAS.

Oct. 12th, 1892.

\*.\* Kingston has a population of some 27,000, which is not large enough to engage the whole services of a medical officer of health. We have always argued against annual appointments because it is unfair to put the medical officer of health in the position of submitting to an annual chance of losing his office, a result which has often happened if by too much zeal he has offended any members of his Authority. The proper course for Kingston is to combine with other districts, and in this way secure the whole time of a medical officer.—ED. L.

## ROYAL MEDICAL BENEVOLENT COLLEGE.

To the Editors of THE LANCET

SIRS.—I feel assured you will find room to insert the following most gratifying correspondence between the teaching staff of Epsom College and the Council. The evidence of such a body of men must be pleasing confirmation to you that the munificent aid you have given has been rightly bestowed. I shall most gladly receive any contributions towards these most necessary objects—a larger charity to our pensioners and increased accommodation for our pupils.

I am, Sirs, yours faithfully,

C. HOLMAN, M.D., Treasurer.

26, Gloucester-place, Portman-square, W., Oct. 10th, 1892.

Bursar's Office, Epsom College,  
Oct. 4th, 1892.

DEAR SIR.—I have to-day forwarded to the Secretary a donation which the members of the Common Room here would like to subscribe to the Extension Scheme Fund as set forth at the Biennial Festival in April last.

Believe me, very faithfully yours,

W. DOUGLAS CROSSLEY, Bursar.

Royal Medical Benevolent College Office, 87, Soho-square, W.,  
Oct. 7th, 1892.

DEAR SIR.—I am instructed to inform you that the donation from the Masters of Epsom College towards the extension fund has been received by the Council with very great pleasure.

The generally improved tone of the school, the distinctions gained by pupils at the universities and elsewhere, and the successes in the playing fields all point to good work done by the staff and most loyal and hearty devotion to the best interests of the College.

Such a practical expression of confidence in the future of the school and belief in the necessity for extension by those so well qualified to know is most gratifying. The Council would assure the contributors that this question of enlarging the accommodation is constantly the subject of their thoughts, and they would express the hope that this gift coming from such a body of men may prove to the profession and to the public how necessary extension has become, so that many may be incited to follow their example.

The larger charity to the pensioners needs no demonstration.

The desire of the Council has always been to feel that they were in touch with their staff.

They believe that this donation in aid of their work is a proof that the Masters feel themselves to be at one with the Council in their earnest desire to make Epsom College one of the best schools in England. With hearty cooperation they hope to see the College a blessing to the children of medical men and a centre from which a first-rate education shall be offered to the public at large.

I am, dear Sir, yours faithfully,

J. BERNARD LAMB, Secretary.

W. D. Crossley, Esq., Bursar of Epsom College.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### Opening of the Medical Institution for the Winter Meetings.

THE first meeting of the Medical Institution for the present season took place on the evening of Thursday, the 6th inst., and was very well attended, there being 160 members and associates present. An address was given by the President, Dr. Thomas R. Glynn, on the Diagnosis of Hysteria. It was an extremely able discourse, well illustrated with cases, diagrams, tables &c., and it is satisfactory to learn that it will be published, as it will form a valuable addition to the literature of the subject. Mr. John Newton followed with an address on Art. Cordial votes of thanks were passed to both of these gentlemen, and the meeting adjourned to another part of the building, where a substantial supper was provided and a most agreeable evening was passed.

### Mr. Mitchell Banks's Address at Leeds.

The address delivered at Leeds by Mr. Mitchell Banks of this city is a very felicitous illustration of the advice given by him in an address at the Medical Institution here last winter. In it he urged his brethren to cultivate the reading of good general as well as medical literature. It will be seen from a perusal of the lecture published in THE LANCET of last week that Mr. Banks does not confine either his remarks or his attention to English literature, but embraces French as well. Even the hardest worked members of the profession have some leisure, and this example of "learned leisure" may well be followed.

### Medical Students and Doctors in Fiction.

It is somewhat remarkable that while Dickens's well-known characters, Benjamin Allen and Bob Sawyer, still continue to reappear every recurring October, how very little account is taken of another character drawn by the same master hand—that of Allan Woodcourt, the nobly self-denying young doctor in "Blenk House." The concluding words of the story, in which the doctor's wife describes their happy life and the esteem in which her husband is held by rich and poor alike, are among Dickens's finest writings, and yet how seldom they are heard or quoted. The student career of Allan Woodcourt must presumably have been very different from that of Benjamin Allen or Bob Sawyer, nevertheless the public cling to these two with a tenacity worthy of better subjects. Similarly, in the two characters of Mr. Samuel Huxter and Dr. Firmin the immortal Thackeray has portrayed two very undesirable specimens of members of the profession. But his Dr. Goodenough is a noble character, of which any profession may be proud. The original is said to be the late Dr. John Elliotson, to whom its author dedicates his famous work "Pendennis" in the following terms: "Thirteen months ago, when it seemed likely that this story had come to a close, a kind friend brought you to my bedside, whence in all probability I never should have risen but for your constant watchfulness and skill. I like to recall your great goodness and kindness at that time, when kindness and friendship were most needed and welcome, and as you would

take no other fee but thanks, let me record them here in behalf of me and mine and subscribe myself—Yours most sincerely and gratefully, W. M. Thackeray.”

Liverpool, Oct. 12th.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *Victoria University.*

THIS year the authorities of Owens College have made a new departure which is calculated not only to further the cause of education, but also to increase public sympathy with university work in Manchester. A prospectus has been issued by Dr. Ward, Principal of the College, intimating that during the ensuing winter months a course of popular evening lectures will be given in the College, admission to which will be free—i.e., by tickets, any number of which will be obtainable on application to the Registrar. The syllabus of lectures is an attractive one, and contains the names of many of the professors and teachers of the College as lecturers in this course, our much respected Principal himself delivering the opening lecture. I shall be much surprised if Manchester does not show its appreciation of this public-spirited act on the part of the College staff, many of whom are busy men already fully employed in ordinary tutorial work.

### *Ancoats Healthy Homes Society.*

It is fortunate for the slum-dwellers of our city that the working people of “Old Manchester” have recently adopted the rational plan of associating themselves together for the purpose of bringing pressure to bear on the constituted authorities for the improvement of the districts and houses in which they are forced by circumstances to spend their lives. As the Ancoats district is well known to be one of the dirtiest and most neglected in the city, it was appropriately the first to bestir itself for purposes of self-help in the matter of health. Accordingly the Ancoats Healthy Homes Society, whose fourth winter session was inaugurated last week, was the pioneer association of this kind formed in Manchester. At the New Islington Public Hall the first lecture of the season was delivered to a crowded meeting on Thursday evening last by Dr. Pankhurst, a distinguished member of our local bar, who gave a stirring and most interesting address on the subject, “Health and Responsibility, Individual and Corporate.” Monthly, evening meetings will be held throughout the coming winter and spring, either at the New Islington Hall or at some other large public building in the district of Ancoats; and from the names of the gentlemen (and ladies also) who have undertaken to address future meetings one is led to augur favourably of the success of the current session.

### *The Watercloset System.*

At a meeting of our City Council on Wednesday last several matters of sanitary importance came on for discussion. The sanitary committee proposed that, with the object of superseding the “pail system” which several years ago was adopted here in place of the filthy midden of olden time, the watercloset system should now be made universal in Manchester. The chairman, Alderman Smith, candidly stated that inasmuch as the pail system had been forced upon the property owners of Manchester against their will some fifteen years since it would be unjust to saddle them now with the cost of its reconversion into waterclosets simply in obedience to the will of the Council. He thereupon suggested that, in obtaining Parliamentary powers for the conversion of the pail-closets of Manchester into waterclosets, the corporation should seek permission to pay out of the rates half the cost of such conversion and of the necessary reconstruction of the drains in connexion therewith. The seriousness of the proposal, involving as it does the dealing with closet accommodation for 98,000 tenements, at a cost of half a million sterling, was properly acknowledged and the usual device adopted of referring the matter to the committee for “further consideration.” As, however, the Council had previously decided that Manchester should eventually become a water-closetted town, there is no doubt that the committee will ultimately have their way. Practically the only question which remains for debate is the important one of the incidence of cost. The committee think that justice will be satisfied if the total cost, estimated at £452,000, is divided between the

Corporation and the property owners, but the latter retort, through their representatives, that when the conversion of the old middens into pail-closets was commenced in 1874 the Corporation gave an undertaking that any further change in the closet system should be paid for by the Corporation and not by the property owners. As the whole question is now being fairly and publicly discussed it is to be hoped that an equitable and permanent settlement will shortly be arrived at.

### *River Purification.*

At last the joint committee appointed some time since for dealing with the pollution of rivers in the Mersey and Irwell watershed have shown themselves really in earnest. They have already instituted proceedings against the Corporation of Bury, and have ordered the prosecution of the local boards of Chadderton, Dunkinfield, Marple and Gorton. At a meeting of this committee in Manchester on the 3rd inst. extension of time for the execution of necessary sewage works was granted to several local sanitary authorities in the watershed. Attention was drawn to the difficulties encountered by this committee in consequence of the tardy action of the Local Government Board. In consequence of the recent change of Government a deputation was appointed to wait upon the new President of that Board, urging the need for an unusual degree of attention in regard to their treatment of sewerage schemes generally. A further resolution was also passed, at the instigation of Mr. Hibbert, M.P., formally drawing the Board's attention to the great delays which ordinarily took place in these matters, and urging the necessity that in future the Board should deal with such sewerage schemes as may be submitted to them with as little delay as possible.

Oct 11th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *University of Durham College of Medicine, Newcastle.*

THE winter session of the University of Durham College of Medicine, Newcastle, was inaugurated by the Bishop of Durham, who gave an address and distributed the prizes. In reference to the late Dr. Heath's gifts to the College, he said he not only admired the munificence of his bequests, but also the wisdom with which he had directed them to be distributed. In respect of the proposed enlargement of the College in the way of a residential hall, he said that the fellowship of common residence was one of the greatest privileges of a college, and he trusted that before long the students of that College of Medicine would have the enjoyment of the crowning privilege of university life.

### *Rutherford Memorial College, Newcastle.*

The foundation-stone of the Rutherford Memorial College was laid on Wednesday last by Mr. Joseph Cowen, who was one of the late Rev. Dr. Rutherford's oldest and warmest supporters. The college will cost about £15,000, and when fully completed and equipped will afford means of supplying an intermediate and high-class education. Mr. Cowen also distributed the prizes, and delivered an eloquent oration in the evening at the meeting, which was well attended by all classes of citizens.

### *New Degrees in the University of Durham.*

The University of Durham has just added two more degrees to the already comprehensive list which is available for those who undertake the study of medicine in connexion with its university. The degrees in question are to be known by the symbols “B. Hy.” and “D. Hy.,” or, more explicitly, Bachelor and Doctor in Hygiene respectively. The course will not only partly cover the ground comprised in the “D.P.H.” and the diploma in Public Health granted by several of the other universities, but it will also include examination in such subjects as bacteriology, vital statistics, sanitary medicine &c.

### *An Alleged Death from Vaccination at Sunderland.*

An inquest was held at Sunderland on Saturday last on a child aged five years, who was said to have died from the effects of vaccination performed nearly five years previously. It was shown by the mother that the child had always been healthy up to the age of five months, when it was vaccinated. Since then it had sore eyes and abscesses, and had been generally ailing. She stated that she had thirteen children, six of whom died in infancy from teething

and convulsions. At this stage the coroner said he would adjourn the inquiry in consequence of an intimation from the Home Office that whenever an allegation of death from vaccination took place a representative from the Royal Commission on Vaccination would attend the inquiry. The inquest was accordingly adjourned. A post-mortem examination was in the meantime to be made. I shall make no remarks here on this case further than that five years seems a very long time to go back for the cause of death in the case.

#### *North Riding Infirmary, Middlesbrough.*

The report of the working of the North Riding Infirmary at Middlesbrough shows a serious deficit in the funds for the last half year amounting to £432, owing to the disastrous effects of the Durham colliers' strike. Not only this, but the stoppage of works consequent on the strike checked the regular contributions of the workmen to the extent of £253 and greatly interfered with the other collections in aid of the Hospital Sunday and Saturday Funds and also with the attendances at the charity football matches.

#### *Proposed Cottage Hospital at Morpeth.*

It is proposed to erect a cottage hospital at Morpeth at an expense of, say, £1000; but Morpeth should have the courage, considering the importance of the town and district, to venture beyond this and to provide a cottage hospital suitable for its requirements.

#### *Workmen's Hospital Demonstration.*

On Sunday last the workmen of Houghton-le-Spring Friendly Societies paraded and marched to church to a special service, and it is said 1000 attended, after which a collection was made in aid of the Grange-over-Sands Convalescent Homes.

#### *Royal Infirmary, Newcastle.*

There is a vacancy at the Newcastle Royal Infirmary for the vacant post of assistant-surgeon. Mr. T. Dodd, who has just resigned, held the post for, I believe, fourteen years.

I hear that his Grace the Archbishop of York has consented to preach the sermon at St. Nicholas' Cathedral, Newcastle, during the forthcoming meeting of the British Medical Association.

Messrs. Mawson, Swan and Morgan of this city have published an excellent autotype likeness of the late Dr. Heath—not for profit, but to enable his many friends and late pupils all over the world to possess it.

Newcastle-on-Tyne, Oct. 11th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Appointments to the Royal Infirmary, Edinburgh.*

LAST week the managers of the Royal Infirmary elected Dr. Ralph Stockman and Dr. G. Lovell Gulland, assistant physicians, and Dr. David Wallace, F.R.C.S. Edin., and Dr. Alexis Thomson, F.R.C.S. Edin., assistant surgeons to the institution. Owing to Dr. Brakenridge and Dr. John Dnucan having completed their term of office in the infirmary as physician and surgeon respectively, Dr. James has got charge of a ward, and Dr. McGillivray, as senior assistant surgeon, has also got wards. Dr. Brakenridge has been appointed a consulting physician. Owing to the generous action of Dr. A. G. Miller Dr. Duncan's connexion with the surgical wards is still retained, Dr. Miller, with the sanction of the managers, having handed half his beds over to Dr. Duncan. This is felt to be a distinct gain to the hospital and highly creditable to Dr. Miller. Dr. Bramwell, as senior assistant physician, is to have charge of the wards for the clinical instruction of women in medicine, and Dr. Cotterill, as senior assistant surgeon, those for clinical instruction in surgery to the same body.

#### *Opening of the Winter Session, Edinburgh.*

The winter session commenced on Tuesday. There was no opening function of any kind.

#### *Leith and the Board of Supervision.*

As has been already mentioned here, the report by the inspector appointed by the Board of Supervision as regards the sanitary condition and arrangements at Leith did not show a satisfactory state of matters in that burgh. The local authority did not like the report and have rather resented the action of the board. The board has, however, written a

letter to them saying they have no desire to enter upon a controversy with the local authority, that their aims are the same, and suggesting a conference between the board and the local authority.

#### *Health of Aberdeen.*

During last week 176 cases of measles and 69 cases of scarlet fever were reported in the city of Aberdeen, making, with 6 cases of diphtheria and 2 of erysipelas, a total of 253, an increase of 67 as compared with the previous week. In the county 48 cases of zymotic diseases were reported, including 30 of measles, all in one suburb of Aberdeen.

#### *Aberdeen District Nursing Association.*

The first quarterly meeting of the general committee was held this week, Dr. A. Fraser presiding. Miss Armstrong's report for the past three months showed that 46 new cases had been entered on the register and that 1g were still under treatment. During the quarter 732 visits had been paid. It was intimated that suitable lodgings had been secured for Miss Armstrong and an assistant nurse. Gifts of old linen, nourishing food and articles of clothing had been received. It was agreed to circulate a pamphlet describing the aim and working of the Association.

#### *Opening of the Aberdeen University Medical Session.*

On Tuesday, the 11th inst., the winter session of the medical classes was commenced. There was a good attendance in all the classes. Professor Cash, F.R.S., made reference to the new ordinances, and expressed the opinion that the commissioners had made a mistake in placing materia medica and pathology in the same year. He thought it was also matter for regret that the number of meetings for practical work in materia medica had been reduced from fifty to twenty-five. Professor Ogston also referred to the new regulations and complained that too much effect had been given to the theoretical rather than to the practical teaching of surgery. He referred to his appointment as surgeon-in-ordinary to Her Majesty the Queen, and said that he regarded it as a high distinction conferred upon the medical profession in Aberdeen, the medical school and the University. He also spoke of the kindness shown him by the directors of the infirmary, and he was glad to say that he would have more opportunity of meeting with the students at the infirmary than formerly.

#### *Extension of Marischal College, Aberdeen.*

At a meeting of Aberdeen University Court this week Lord Huntly read the following letter from Mr. Charles Mitchell, Newcastle-on-Tyne:—"To remove any doubt as to the terms on which I wish to obtain permission to build the proposed block in the rear of Marischal College, your lordship might have the goodness to state to the Court that my desire is to build the block in question to contain a graduation hall and a students' union; the only conditions I attach to the arrangements are that the plans be approved by the University Court and the Executive Committee, and that the work be completed to their satisfaction." The letter was received with hearty applause by the members of the Court. The Lord Rector (the Marquis of Huntly) mentioned that the gift involved a sum of not less than £13,000.

#### *Induction of Professor William Macowen at Glasgow University.*

At a meeting of the University Senate held last week Dr. Macewen presented the Commission from the Crown appointing him to the chair of Surgery in succession to the late Sir G. II. B. Macleod. In accordance with the ancient usage, which requires a newly appointed professor to "make trial of his abilities" by reading a Latin essay on some scientific theme prior to his induction, Dr. Macewen read a paper entitled "Quibus Indiciis Externis Locus Suppurationis in Cerebri Regione Temporo-sphenoidali Recte Reperitur." This essay having been gravely listened to and approved by the Senate, Dr. Macewen signed the declaration *de fidei*, was duly inducted into his chair, and took his seat as a member of the Senate.

#### *Chair of Pathology in Glasgow University.*

An announcement of great importance for the welfare of the university was made at the last meeting of the University Court—namely, that Miss Agnes Barr of Carphin, Cupar-Fife, had given a sum of £2500 to endow or assist in endowing a chair of Pathology in the University. This should enable the Court to do what ought to have been done years ago—to erect the extra-mural lectureship on Pathology into an intra-mural professorship, and thus do away with the ridiculous injustice that a teacher who taught a compulsory subject and performed

all the functions of the professor in the way of lecturing and conducting professional examinations should be regarded as an extra-mural teacher and deprived of senatorial rank, simply for want of a trifling endowment. It should also permit of the removal of a long-standing grievance of extra-mural teachers—that pathology being treated as an extra-mural class, and students being compelled to take it, the four subjects which University students are ostensibly allowed to take extra-murally amount in reality only to three.

#### Professional Examinations.

The published list of those who have passed the Second Professional Examination at the University contains 64 names. The first professional list contains 104 names, including, for the first time in the history of the University, those of eight ladies.

#### A "Black List" for Coatbridge.

The practitioners in Coatbridge have formed an association, among the members of which is to be circulated periodically a list of those in the district who are bad payers and who are apt to go round from one medical man to another, victimising each in turn. It is to be regretted that the moral tone of Coatbridge should have rendered such action necessary, but the practitioners concerned will have to exercise much care to prevent injustice being done to the poor and impecunious.

Oct. 11th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### Royal Academy of Medicine.

THE annual general meeting of the Academy will be held in the Royal College of Surgeons on Friday, the 28th inst., when the report will be submitted and the election of officers will take place. There will be vacancies for members of Council in the Sections of Medicine, Surgery, Obstetrics, Pathology, Anatomy and Physiology, and State Medicine.

#### Royal University of Ireland.

A general meeting of the graduates was held this week, presided over by Dr. A. L. Stuart. The report of last year's conversazione committee was submitted and adopted, and it was agreed to hold a conversazione in the university building on Friday evening, the 28th inst. A committee was appointed to carry out the necessary arrangements.

#### Royal College of Surgeons.

A supplemental preliminary examination, under the regulations of the conjoint Colleges of Physicians and Surgeons, will be held on Nov. 2nd and 3rd, to enable students to commence their medical studies for the present winter session. Stanislaus Zichy-Woniarski, M.B., B.Ch., University of Melbourne, has obtained the Fellowship of the College.

#### The International Medical Congress, Rome, 1893.

It is rumoured in medical circles in Belfast that the attention of the officials of the coming International Medical Congress at Rome will be drawn to the extraordinary constitution of what is called "the committee for Ireland" (as published in THE LANCET of Oct. 8th) in connexion with that meeting. It would appear that this committee consists of twelve members, of whom eleven reside in Dublin and one in Belfast. If such a body were called "the Dublin committee" one could understand the designation; but to style it "the committee for Ireland," when Belfast, the seat of one of the largest colleges and medical schools in the country, is allowed the honour (?) of having only one representative, while the rest of Ireland, outside Dublin, is completely ignored, is little short of an insult to the great body of the medical profession in this country. Imagine Sir James Paget selecting eleven medical men in London and one in Birmingham, Leeds, or Liverpool, and calling such a body "the committee for England," or Professor Grainger Stewart nominating on "the committee for Scotland" eleven representatives from Edinburgh and one from either Glasgow or Aberdeen!

#### The Winter Session.

The winter session of the medical school will open on the first week in November, and Dr. Nelson is to give the introductory address at the Royal Hospital on Nov. 1st. A movement is at present on foot to give a dinner at the beginning of the new year to teachers and old students of the Belfast Medical School.

#### Extra-uterine Gestation.

Dr. Byers performed an abdominal section on an interesting case of ectopic pregnancy at the Royal Hospital, Belfast, on last Tuesday week. The patient on admission was very anæmic from great intra-peritoneal hæmorrhage, and at the operation the ruptured tube and the ovum (which was found amongst the intestines) were removed. She has had a rapid recovery. This, I am told, is the first case of ectopic gestation which has been treated by abdominal section in Belfast. Dublin, Oct. 12th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### The Disposal of the Insane of Paris.

I ANNOUNCED in a former letter the despatch to London, Edinburgh and Glasgow of a commission appointed by the Paris Municipal Council to study in those centres the methods utilised by water companies for the filtering of water supplied by such companies. M. Pétrot, a member of the commission (now returned to Paris), has, in a conversation with a representative of *Le Temps*, communicated his impressions concerning the plan of filtering adopted by the Lambeth and Kew Companies. While objecting to the replacing, after washing, of the upper layer of sand in the filtering bed—he thinks fresh sand should be used—he sums up by saying that the system, simple and primitive though it be, is productive of excellent results. He believes that the same method might with certain improvements be usefully put into practice in Paris for the supply of water taken from the Seine up-stream, until we obtain that great desideratum—a plentiful and constant supply of good spring water. But your readers will be asking what the water-supply has to do with the disposal of the insane. Well, M. Pétrot states that the labours of the Commission were not limited to the study of the water question, but that they took advantage of their stay in Edinburgh and Glasgow to inquire into the working of the system by which lunatics are treated either at the un-asylum-like Royal Asylum of Glasgow or as boarders in private families in the neighbourhood of the Scottish capital. M. Pétrot appears to have been most favourably impressed, and he strongly advocates the founding in Paris of an institution analogous to the Glasgow Royal Asylum. The Commission visited several villages counting amongst their inhabitants the mentally degenerated of Edinburgh. They could not fail to notice the *bien-être* of these poor harmless creatures and their happy, if stupid, mien, so different from the discontented or, at best, resigned demeanour of the demented who crowd the close and malodorous Paris asylums. Last year the General Council of the Department of the Seine voted a trial of this home treatment of the harmless insane. The first essay will be made next spring. One hundred of the mentally affected will be distributed amongst the families of Dun-sur-Auron, a commune of the Department of the Cher. The plan will subsequently be generalised, and it is hoped that private asylums will gradually disappear, to the great advantage of the insane of this city.

#### The Curative Action of High Temperature on Wounds.

The complete removal of tissue invaded by tubercle by means of instruments is in most cases a matter of difficulty, and the surgeon is obliged to supplement cutting by the application of caustics such as zinc chloride or of the thermo-cautery, but even then tuberculous nodules may be left and disappointment result. M. Félizet of Paris recently gave a trial to a blowpipe flame giving a temperature, as tested by the pyrometer, of 1500° to 1600° C. The blowpipe is fed with a mixture of one-third air and two-thirds petroleum. With this flame the morbid spots on the surface of the operation wound are "licked," so to speak, for a few seconds. The tissue immediately shrinks, the blood coagulates, but there is neither charring nor hæmorrhage. In a case of resection of the knee-joint, a forty seconds' contact of the flame suffices. M. Félizet has derived good results in thirty-eight cases, which comprised excision of the knee, hip, and elbow-joints, and the treatment of tuberculous abscesses. M. Nélaton states that he operated on two cases of cancer of the os uteri, the operation consisting of scraping, followed by the application of the flame yielded by the gas cautery invented by his illustrious father. By this means recurrence was, in both instances, long delayed. M. Félizet reminds us that the thermo-cautery

at dull red has a temperature of 700° C., and at white one of 1400° C. Charring of tissues occurs at these temperatures, which is not the case with his blowpipe flame at 1500° to 1600° C. M. Moty claims for the thermo-cautery at a white heat that held at a certain distance from a wound-surface it produces a kind of erection of the granulations and brings about a more rapid cicatrization. He believes that heat influences the vitality of the tissues and that the destruction of the germs which infest them is altogether a subsidiary process.

#### *Deaths under Chloroform.*

An order has been issued by M. Peyron, Chief of the Assistance Publique, to the directors of hospitals in Paris, to render an account of all accidents caused in their establishments by chloroform inhalation. The following details are to be furnished: the date of the accident, the service in which it occurred, the name of the surgeon, the name, age and profession of the patient and the malady or operation necessitating the administration of chloroform. These statistics will go back to April 1st, 1890.

#### *Continental Anglo-American Medical Society.*

The annual meeting and banquet of this young but useful Society took place on the 6th inst. at the Grand Hôtel, Paris. A fair sprinkling of British and American practitioners residing on the Continent attended both functions, the company including Drs. the Hon. Alan Herbert, Chapman, Dupuy, Maure-Miller, Hogg, Austin, Bull, Hjalstead Boyland and Barnard of Paris; St. Clair Thomson (Florence), Brandt (Royat), Bagnell (Pau), Cormack (Viçhy), Linn (Nice), and Gilchrist (Nice). Drs. Polk, Keyes, Lusk and Jacobi of New York, Dr. Wilks, F.R.S., and Mr. Nunn of London were elected hon. presidents, five new members were admitted and Drs. Warren Bey, Clarke, Austin and Hjalstead Boyland were selected by ballot to fill the vacancies in the executive committee. Dr. Barnard of Paris was unanimously elected hon. secretary to the Society in the place of Dr. Ball, who is now hon. treasurer. The dinner, presided over by Professor Peter, was a decided success. The guests included Mr. Malcolm Morris of London, Dr. Seely of Cincinnati, and Drs. Budin, Gellé, Vidal and Apostoli of Paris. The Society now numbers over 100 members, and everything points to a career of long-continued prosperity and usefulness. The hon. secretary, Dr. Barnard (362, Rue St. Honoré, Paris), will, I understand, be glad to supply any information concerning the scope and objects of the Society.

Paris, Oct. 12th.

#### BERLIN.

(FROM OUR OWN CORRESPONDENT.)

#### *A Fatal Mistake by a Druggist's Apprentice.*

A VERY sad case of bodily injury, due to the carelessness of several persons, came before a Berlin court on the 6th inst. On June 14th, 1889, a doctor went to an apothecary's shop to buy bandages and silicate. The articles were not in stock in the quantity required and a promise was given that they should be there next day. A kilogramme of silicate was ordered by telephone from a druggist's, where an apprentice was entrusted with the matter. He went into the cellar with a lamp, fetched a vessel which he supposed to contain silicate, and weighed off a kilogramme of its contents, which was sent to the apothecary. At noon next day one of the apothecary's assistants was relieved by another, to whom he handed the doctor's order with the remark that the bandages and silicate would be called for in the afternoon. When the woman for whose child the dressing was wanted called she received half a kilogramme of the stuff sent by the druggist and went to the doctor, who, with the assistance of a younger doctor, laid the bandage round the child's leg. It struck the older doctor at the time that he noticed a burning feeling in one of his fingers, but he attached no importance either to that or to the vehement and incessant crying of the child. Next night he awoke with severe inflammation in his finger. It occurred to him that a mistake might have been made: Early next morning he took some of the fluid to a chemist, who at once ascertained that it was a solution of caustic soda. He hastened to his patient and took off the bandage. The skin was all destroyed, and the leg had to be amputated to save the child's life. The druggist and one of the apothecary's assistants were fined 300 marks (shillings), the

druggist's assistant, who had entrusted the order to an apprentice, 100, and the apprentice 30. The doctor has disappeared.

#### *Miscellaneous Items.*

The library of the Berlin Medical Society has been removed to the Langenbeck House.

The late Professor Hermann von Meyer bequeathed his valuable anatomical collection to Senckenburg's Institute in his native city, Frankfort-on-the-Main.

Berlin, Oct. 11th.

#### NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

#### *The Present Condition of the Maori Race.*

GOVERNMENTAL officers residing in native districts have recently presented to Parliament their annual reports. It is a pleasure to notify that these reports show a distinct improvement in the general condition of the native people as compared with former years. The resident magistrate at Auckland (Mr. H. W. Bishop), for instance, states: "One very important subject for congratulation in connexion with the social state of the natives is their ever-increasing sobriety. This becomes more noticeable every year, and drunkenness is now considered a perfect disgrace." Unfortunately this state of things is not universal in this part of the colony, for the resident magistrate goes on to state that "there are a few places in the north where the resident natives unfortunately show themselves to be the exception to what I may term the rule." Again, the native agent at Otorohanga forwards a very voluminous report, and sums up the social condition of the Maoris in the King country in the following words: "It is satisfactory to be able to report that they still remain remarkably temperate, and crime of a serious nature is very rare amongst them." Mr. Bedwell, at New Plymouth, too, adds for his district "that the drinking habits of the natives have very much decreased during the last year or two." Mr. Booth, resident magistrate at Gisborne, states "that the natives on the east coast as a whole have almost entirely given up drinking; it is very rarely now that a native is brought up on a charge of drunkenness." The report received from Captain Preece, resident magistrate at Kaiapoi, runs in a similar strain, for he says "the natives seem to be remarkably sober." From the above very satisfactory reports it is no wonder that the general health of the natives is found vastly improved compared with last year. I regret to say, however, that the chief reason why the natives have become so abstemious of late is, in my opinion, due to the fact that they have not any negotiable property to part with. They subsist chiefly on the pittance granted to them by the Government, for the land at present held by them is for the most part so secured that they cannot part with it. If they had more land to sell I fear alcoholic indulgence would be immediately resumed. The general immunity from sickness is not due to other improvements in the mode of living, for the vast majority of the Maoris still cling to the old style of living, although here and there one comes across a native who builds for himself and his family a residence on European lines. In former times, when life and property were not safe in New Zealand, the natives were of necessity obliged to live in fortified paha, much resembling those fortified settlements seen to such perfection near Taormina in Sicily. Their buildings were erected consequently on high land and efficient drainage was thus obtained. Nowadays, however, all this is changed. The Maori settlements are all, or nearly all, situated in low-lying, swampy localities, so as to be handy to their cultivations; the long, low, badly ventilated houses (whares) are usually crowded with men, women and children, and the atmosphere in these whares is simply unbearable to a white man. Carelessness in dress—one day being muffled up and the next nearly naked—and these bad sanitary surroundings are the chief causes of the pulmonary complaints so extremely prevalent among the Maories of to-day. Phthisis is extremely common. Notwithstanding constant warning from the proper authorities, the natives pay no heed to these things, and although they admit the evil they disregard the consequences. It is no wonder, then, that under these conditions the Maori race is gradually but surely diminishing in numbers. Let us hope that the great improvement shown in the general health of the natives owing to their recently acquired temperate habits will

stimulate them to further efforts, and that they will now aim chiefly at sanitary reform in their paha.

Wanganui, N.Z.

## Obituary.

WALTER PYE, F.R.C.S. ENG.

THIS excellent surgeon and most estimable man, one of the surgeons to St. Mary's Hospital, died on Sept. 2nd in his fortieth year. The son of Mr. Kellow Pye, a name both honoured and widely known in the musical world, Walter Pye went when a boy of nine to Magdalen School, Oxford, as a chorister in the college choir, and there it was that his early training and the associations of the place gave him that love of art and literature which so characterised him. When he left school he had no thoughts of medicine, but he wandered and learned much in many lands—first, in the south of Spain, where, under Professor Young, the head of an expedition sent from America to observe an eclipse of the sun, he helped in making observations of the solar corona; next, in China, where he had brothers and friends and where he made the acquaintance of Dr. Manson, and it was the interest aroused in him by the work of this distinguished man that induced him to join the medical profession. On his way home he spent some months in India and thereafter entered as a student at St. Bartholomew's Hospital. He filled in time the appointments of house physician to Dr. Southey and of house surgeon to Mr. Callender and Sir William Savory, and in these capacities he must have made the best use of his opportunities, for his wide knowledge both of the practice and literature of medicine and surgery was very obvious to all who were subsequently brought in contact with him. Physiological inquiries now engaged him, and he wrote on the "Development of the Kidney," and it was as Lecturer on Physiology that he first became connected with St. Mary's Hospital Medical School. A vacancy occurred soon afterwards on the surgical staff of the hospital, and this, when aged only twenty-four, he was elected to fill, so high had been the opinion formed of his surgical attainments at St. Bartholomew's Hospital. That was in 1877, the year before he became a Fellow of the College of Surgeons. At this time also he worked as clinical assistant at Moorfields, and having after a couple of years resigned the chair of physiology, he became surgical tutor at St. Mary's Hospital, and at a later period assistant surgeon to the Victoria Hospital for Children. For some years before his death he had lectured on practical surgery. In all these various offices he worked hard—harder, many thought, than his physical strength could bear. An encouraging success was, however, in store for him, for it is no exaggeration to say that his writings on "Surgical Handicraft" were of a high order of merit. He was the very man to choose this subject for his pen, for his surgical knowledge and experience were large. He had a clear and graceful style, and the work of his own hands was always dexterous. Moreover, apart from occasional papers in the journals, he was the author of works on "Elementary Bandaging and Surgical Dressings" and on "Children's Deformities," and as Professor of Pathology and Surgery in 1890 at the College of Surgeons he gave a course of lectures on "The Growth-rates of the Body in their relation to the Processes of Rectification of Deformity." It was in July of that year that his health began to fail. He had never, indeed, fully recovered from attacks of influenza in the two preceding winters, and he had been overworking himself both by preparation of his lectures at the College and of the forthcoming third edition of his "Surgical Handicraft." Throughout the past twelve months he had not had a day's rest, and when at length he broke down in September it was hoped that prolonged change and quiet might restore him to health. He got three months' leave and went to Cairo with his wife, but when he returned home he was obviously worse, and the suspicion of general paralysis was very soon confirmed. A terrible blow this to his relatives and friends, and to himself also, for he then was conscious and often spoke of what was the matter with him—a blow falling at the very moment when the reward of steady work was certainly at hand. The disease ran its usual course with steadily increasing weakness and enfeeblement, but throughout his illness of two years his thoughts were often of his work which had been arrested and, with the happy hopefulness of the dire malady, of his return in good health to St. Mary's Hospital. Thus there was ended all too soon a life of no ordinary interest, usefulness and

promise, the life of one whose natural disposition, wide culture and varied experience of men and things made him ever a genial and intelligent companion. He will live in the affectionate remembrance of many friends.

ALEXANDER KEILLER, M.D., LL.D., F.R.C.P., &c.

THE death of Dr. Alexander Keiller at North Berwick, on the 26th ult., will be regretted by the medical profession generally, and more especially by those directly associated with the obstetric and gynaecological branches of medical science. Dr. Keiller, who was born in 1811, took the degree of M.D. at the University of Edinburgh in 1835. As a teacher of midwifery in the extra-mural school, Edinburgh, he earned distinction of a very high order, and was the inventor of many instruments now in common use in connexion with obstetrics and gynaecology. He was an intimate friend of Sir James Young Simpson. For many years he acted as physician for the diseases of women at the Edinburgh Royal Infirmary, and was also physician to the Edinburgh Maternity Hospital. At the University of St. Andrews, University of Edinburgh, and Royal College of Physicians and Surgeons he held the post of examiner. He was greatly liked by his professional brethren, and his opinion was much valued by his old pupils in cases of difficulty. Dr. Keiller was a Fellow of the Obstetric and Medical Chirurgical and Harveian Societies of Edinburgh, an Hon. Fellow of the Obstetrical Society of London, and an hon. member of the Gynaecological Society of Boston, U.S.

## ROYAL COLLEGE OF SURGEONS.

At a quarterly meeting of the Council held at the College on Thursday, the 13th inst., Mr. Thomas Bryant, President, in the chair, the minutes of the ordinary Council of Aug. 1st were read and confirmed. The Secretary reported the death of Mr. Edward Cook, J.P., past president and member of the Council and Court of Examiners of the College, and also of Mr. Samuel A. Lane, a past member of the Council and of the Court of Examiners of the College, and the Council unanimously passed a vote of condolence with their respective families.

Mr. Davies-Colley was admitted a Member of the Court of Examiners. The appointment of Examiner in Anatomy which he thus vacates will be filled in December.

It was agreed that, as recommended by the Committee for General Purposes, a sum not exceeding £120 be expended in fitting up the room next to the Secretary's office as a common room for the Fellows and Members.

It was agreed on the recommendation of the Committee of Management to recognise the Lancashire County Lunatic Asylum at Rainhill for the attendance required by the regulation referring to clinical demonstrations.

In pursuance of the rules laid down by the two Colleges in December, 1890, relating to the recognition of Laboratories for the Course of Practical Instruction required by the regulations for the Diploma in Public Health, returns have been furnished by the lecturers of the courses delivered at St. Bartholomew's Hospital and at the Bristol Medical School; and it was agreed that, as such courses fulfil the requirements of the two Colleges, they be now recognised.

It was also agreed that the Durham College of Science be recognised as an institution where candidates may receive instruction in chemistry, physics, practical chemistry and elementary biology for the first examination of the Board.

Mr. Hutchinson was re-elected a member of the committee. Mr. Thomas Bryant, the President, was appointed a member of the same committee in the vacancy caused by the retirement of Sir William Savory, Bart.

Mr. Hulko was re-elected a member of the Laboratories' Committee. Mr. Howse was appointed a member of the Court of Examiners' section of the Board of Examiners in Dental Surgery, Mr. Bryant having ceased to be a member of the Board of Examiners.

The draft report prepared by a committee of the statement to be made to the Fellows and Members at the meeting to be held on Nov. 3rd next was agreed to and will be forwarded to the Fellows of the College on the 20th of this month, on or after which date it can be procured by Members on application.

The Secretary reported that he had received from Mr. Wilde, the solicitor of the College, a cheque for £181 7s. 2d., being the amount of the first promissory note given by Dr. Danford Thomas in respect of the costs of the action of Steele v. Savory.

The Bradshaw Lecture will be given by Mr. C. Heath on Thursday, Dec. 1st next, at 4 P.M. The subject is not yet announced.

## Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen, having previously passed the necessary examinations and conformed to the by-laws and regulations, and having now attained the legal age (twenty-five years), were, at the quarterly meeting of the Council on Oct. 13th, admitted Fellows of the College:—

Eccles, William M'Adam, M.B., L.R.C.P. Lond., St. Bartholomew's Hospital; diploma of Member dated Feb. 13th, 1890.

Pennell, Theodore Leighton, M.B., L.R.C.P. Lond., University College Hospital; Nov. 13th, 1891.

Hamilton, Edward Thomas Ernest, B.Sc., L.R.C.P. Lond., Guy's Hospital; Nov. 12th, 1891.

The following gentlemen, having passed the necessary examinations and having conformed to the by-laws and regulations, were, at the same meeting, admitted Members of the College:—

Cartwright, Ernest Henry, L.R.C.P. Lond., Oxford University and Guy's Hospital.

Cooper, Dossabhoj Nowrojee, L.R.C.P. Lond., Madras and St. Bartholomew's Hospital.

Francis Ernest Edward, L.S.A., St. Bartholomew's Hospital.

**UNIVERSITY OF CAMBRIDGE.**—The following gentlemen have been approved by the Examiners in State Medicine as entitled to diplomas certifying to their competent knowledge of what is required for the performance of the duties of medical officer of health. The names of all those approved are on the Medical Register of the United Kingdom:—

James Barr, M. M. Bowlan, W. H. Brazil, C. H. H. Cameron, William Campbell Downs, James Elias, A. G. R. Foulerton, J. Kingdon Frost, Hugh R. Jones, Masha Alla Khan, Jas. Mason, J. P. Mumby, William Pormowan, Edward Scott, George Severs, John Watson, E. Monkhouse Wilson, and M. G. Yunge-Bateman.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.**—The following have passed the First Professional Examination:—

W. Carroll, T. P. Cormack, E. Corsellis, F. Dudley, L. E. Fannin, Anthony Gill, J. J. Gill, W. Glenn, G. Hungerford, H. Loverock, V. A. Magee, J. D. Murdock, and C. J. D. Odevaire.

**PHARMACEUTICAL SOCIETY OF IRELAND.**—The undermentioned have obtained the Licence of the Society:—

J. W. Harvey, R. S. Chapman, P. P. Lee, G. G. Featherston, R. O. Harman, M. R. Nugent, S. L. Cleland, J. Hill, and T. M. Joze. Three candidates were rejected.

**ROYAL COLLEGE OF SURGEONS IN IRELAND: FELLOWSHIP EXAMINATION.**—Mr. Stanislaus Emil Antony Zichy-Woinarski, M.B., Bac. Surg. Univ. Melbourne, having passed the necessary examination, has been admitted a Fellow of the College.

**SOCIETY OF APOTHECARIES OF LONDON.**—The following candidates have passed the Primary Examination in the subjects indicated:—

*Chemistry, Materia Medica, Botany, and Pharmacy.*—E. E. Evans and P. von Himpf, Royal Free Hospital.

*Chemistry.*—E. G. Adams, M. H. Harris, M. Thorne, and C. S. Vines, Royal Free Hospital.

*Materia Medica, Botany, and Pharmacy.*—C. Adams, A. M. Browne, M. K. S. Holst, E. F. Lamport, and M. Sharp, Royal Free Hospital; W. Alder, Guy's Hospital; G. T. Branson, Queen's College, Birmingham; P. Chown and N. S. Monnier, St. Mary's Hospital; R. S. H. Fuhr, Belfast; A. W. Haines, Birmingham; T. H. Hunt, Owens College; W. Latham, Liverpool; W. H. Tomlinson, Manchester; H. E. Wise, Middlesex Hospital.

*Anatomy and Physiology.*—G. J. Branson and A. W. Haines, Queen's College, Birmingham; G. Broadbent, Yorkshire College; C. E. R. Bucknill, Edinburgh; F. Chown, St. Mary's Hospital; U. M. Fowler and E. L. Mitcheson, Royal Free Hospital; R. S. H. Fuhr, Belfast; T. H. Hunt, Owens College; W. MacLellan, Edinburgh; A. P. Murtz, King's College; H. J. Richards, St. Bartholomew's Hospital; A. T. Savage, Cambridge Union; E. E. Willis and L. F. F. Winslow, Charing-cross Hospital.

*Anatomy.*—C. Basan, Middlesex Hospital; E. C. W. Bensley, St. Mary's Hospital; H. A. Burridge, King's College; P. R. Gango, University College; W. J. Henson, Guy's Hospital; A. Hilton,

Owens College; A. R. McCullagh, Charing-cross Hospital; N. S. Monnier, St. Mary's Hospital; W. A. Montgomery and A. C. Thornton, St. Thomas's Hospital.

*Physiology.*—F. IV. Elkington and A. H. Wade, St. Bartholomew's Hospital; W. H. Tomlinson, Owens College.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on the 11th inst., T. Russel Pickthorn, Esq., Inspector-General, in the chair, the sum of £56 was distributed among the several applicants.

**THE BIDEFORD HOSPITAL SHIP.**—The hulk purchased by the local port sanitary authority for the purpose of an isolation hospital is now lying off Bideford Quay and will, after having been dismantled, be permanently moored in the river opposite Barnstaple.

**GUY'S HOSPITAL.**—At Guy's Hospital the winter session was, as usual, inaugurated by a meeting of the Physical Society, which took place at eight o'clock on the evening of Oct. 3rd, in the anatomical theatre. It was preceded by a house dinner of the students' club, held at half-past six in the dining hall of the college. About 120 students, guests and members of the staff sat down to dinner, amongst others present being Mr. Lushington, the treasurer, Dr. Wilks, Dr. Braxton Hicks, Dr. Pye-Smith, Mr. Davies-Colley, Dr. Brookhouse of Nottingham and many other old Guy's men. After the dinner the company repaired to the anatomical theatre, the seats of which were crowded with students eager to listen to Dr. Wilks's address and the paper by Mr. Maylard of Glasgow, which was to follow the president's speech. The subject chosen by Mr. Maylard (whose address has been published in our columns) was "How to remain a Student through Life," and it was handled in a manner which evoked great enthusiasm amongst his hearers, as he pointed out the true lines of advance in the healing art and the duty of those who would become physicians worthy of their high calling. The meeting over, the company again returned to the college, where tea and coffee were served in the club rooms, and there was a display of instruments, microscopical preparations and photographs taken by members of the society during the past year.

**CHARING CROSS HOSPITAL MEDICAL SCHOOL.**—The following prizes have been awarded for the Session 1891-2:—Llewellyn Scholarship (Certificate and £25), Mr. G. H. Hooper; Golding Scholarship (Certificate and £15), Mr. D. P. Gabell; Governors' Clinical Gold Medal, Mr. S. L. J. Steggall; the Pereira Prize (Certificate and £5), Mr. E. Brown; Anatomy (Senior) (Prize), Mr. W. C. D. Hills; and Certificates to Mr. W. E. Wyborn, Mr. G. B. Clarke, and Mr. W. R. Coldicott; Anatomy (Junior) (Prize), Mr. F. H. Atkinson; Certificates, Mr. L. Brown, Mr. W. W. Gabell and Mr. R. W. Stanistreet; Physiology (Senior) (Prize), Mr. G. B. Clarke; Certificate (Proxime Accessit), Mr. H. Green, Certificate, Mr. M. Molloy; Physiology (Junior) (Prize), Mr. D. C. Rees; Certificates, Mr. J. R. Langley, Mr. F. H. Atkinson, Mr. W. W. Gabell, Mr. B. E. Potter; Practical Physiology (Certificates), Mr. D. P. Gabell, Mr. J. C. Furness, Mr. W. E. Wyborn; Chemistry (Prize), Mr. J. R. Langley; Certificate, Mr. W. H. Park; Practical Chemistry (Prize), Mr. D. P. Gabell; Certificates, Mr. G. B. Clarke, Mr. E. Mosely, Mr. A. R. McCullagh, Mr. W. W. Woolliscroft, Mr. W. H. Goodman, Mr. W. C. D. Hills, Mr. C. S. Gardner, Mr. A. W. H. Edgelow; Osteology (Prize), Mr. G. L. Austen; Certificate, Mr. H. H. Ham; Medicine (Prize), Mr. N. R. J. Rainier; Certificates, Mr. T. E. Sandall and Mr. P. J. Probyn; Practical Medicine (Prize), Mr. W. T. White; Certificates, Mr. T. W. Goldney and Mr. T. E. Sandall; Surgery (Prize), Mr. W. J. Robertson; Certificates, Mr. E. Brown, Mr. T. E. Sandall, Mr. E. J. Godwin, Mr. P. J. Probyn; Therapeutics (Prize), Mr. V. P. Footo; Certificates, Mr. H. H. Woods, Mr. S. L. J. Steggall and Mr. J. E. H. Phillips; Materia Medica (Prize), Mr. G. B. Clarke; Certificate (Proxime Accessit), Mr. H. J. Stevens, and Certificates, Mr. W. Hardcastle, Mr. W. C. D. Hills, Mr. P. J. Probyn, Mr. W. R. Coldicott; Midwifery (Prize), Mr. P. J. Probyn; Certificates, Mr. A. E. Hine, Mr. W. T. White; Forensic Medicine and Toxicology (Prize), Mr. W. T. White; Certificates, Mr. S. L. J. Steggall and Mr. A. E. Hine; Pathology (Prize), Mr. H. H. Phillips; Certificates, Mr. T. H. Symons, Mr. A. Hudson; Public Health (Prize), Mr. H. H. Woods; Certificates, Mr. S. L. J. Steggall and Mr. J. E. H. Phillips; Dental Surgery (1st Prize), Certificate and £6 6s., Mr. H. J. Stevens; 2nd Prize, Certificate and £4 4s., Mr. E. W. Harwood; Certificates, Mr. J. W. Tomlinson and Mr. F. T. Trott.

**BEQUEST.**—Mrs. Winifred Hunter has left £200 to the Mater Misericordiae Hospital, Dublin.

**MR. ROBERT McNICOLL**, the Medical Officer of Health of St. Helens, was, on the 6th inst., entertained at a complimentary dinner by the members of the Medico-Ethical Society, of which he is president.

**NEWBURGH, N.B.**, is to be supplied with a thorough system of drainage and an increased water-supply, the benefits of which the inhabitants of the district as well as its numerous visitors will no doubt thoroughly appreciate.

**A NEW HOSPITAL FOR INFECTIOUS DISEASES.**—At the Felixstowe and Walton Local Board meeting last week it was announced that the Local Government Board were prepared to hold an inquiry into an application by the former board to borrow £21,000 for sewerage purposes.

**INFECTIOUS DISEASES IN NEW YORK.**—The following are the number of cases and deaths reported to the Health Department for the fortnight ending Sept. 27th:—Typhoid fever, 126 cases and 36 deaths; scarlet fever, 102 and 19 deaths; measles, 55 and 8 deaths; diphtheria, 116 and 54 deaths; small-pox, 12 and 3 deaths; and cholera, 6, all fatal. There were no cases of typhus fever reported.

**SURGICAL AID SOCIETY.**—At the town hall of Brighton last week the Lord Mayor (Alderman Dr. Ewart) presided over a meeting of medical gentlemen to consider the advisability of establishing a local branch of the above Society. The subject had, it appears, succeeded in interesting a number of influential people in the town. After Mr. Tressider had given a detailed account of the work of the parent society it was unanimously resolved, on the motion of Rev. Prebendary Hannah, to establish a branch of the Society for Brighton and Hove.

**THE METROPOLITAN ASYLUMS BOARD.**—The number of patients remaining in the several fever hospitals of the Metropolitan Asylums Board at midnight on Oct. 11th was as follows:—Eastern Hospital, 400 scarlet fever, 62 diphtheria and 45 enteric fever; South-Eastern Hospital, 396 scarlet fever, 24 diphtheria and 12 enteric fever; North-Eastern Hospital, 138 scarlet fever; North-Western Hospital, 405 scarlet fever, 104 diphtheria and 23 enteric fever; Western Hospital, 303 scarlet fever, 44 diphtheria, 1 typhus and 18 enteric fever; Northern Hospital, 907 scarlet fever and 17 diphtheria; and at the Gore Farm Hospital there were 788 cases of scarlet fever. The hospital ship *Atlas* had 3 cases of small-pox.

**FOOTBALL CASUALTIES.**—During last week the following casualties occurred. While playing in a school match at Barnes two youths collided, one sustaining a fracture of his left leg, just above the ankle, and the other a dislocation of his humerus.—In a match between the Belper Reserves and Heanor teams a player severely injured his knees and was admitted into the Infirmary at Derby.—In a match on the Holderness-road ground between Hull A and Batley A clubs a Batley forward fractured one of his ribs.—In the course of a match at Kinross a player fractured his right leg above the ankle, and a member of the Baillieston Thistle Reserved, Lanark, whilst playing in a match, fractured his clavicle.

**PRESENTATION OF A MEDALLION TO THE ROYAL INFIRMARY, ABERDEEN.**—The proposal which was made some time ago to the directors of the Royal Infirmary by Drs. Ogston and Blaikie Smith on behalf of the staff, and favourably received by them, has now taken practical shape by the presentation of a medallion of the late Dr. Alexander Kilgour by his widow and son. The proposal was to have marble medallions of some of the chief past medical and surgical officers of the Infirmary placed within the hospital. The first of these will be the medallion of Dr. Kilgour, which has been executed by Mr. John Hutchinson, R.S.A., and temporarily placed in the pathological theatre of the newly opened wing. The medallion is executed in high relief and bears the following inscription:—"Alexander Kilgour, M.D., Clinical Lecturer 1838-1864. Born 1803. Died 1874. Presented by his Widow and Son."

**MEDICAL MAGISTRATE.**—Dr. A. Johnston of Ambleside has been placed on the Commission of the Peace for Westmoreland.

**CHESTER GENERAL INFIRMARY.**—The funds of this hospital have by the generosity of the Duke of Westminster been enriched to the extent of £600 by the proceeds of fees paid by visitors to Eaton Hall.

**VACCINATION.**—Mr. William F. Carter, public vaccinator of Bedminster, has again received a handsome award for successful vaccination from the Local Government Board.—Mr. F. N. Williams, district medical officer for Brentford, has been awarded a gratuity of £28 for the satisfactory performance of vaccination in his district.

**CHEPSTOW DRAINAGE SCHEME.**—After an official inquiry into the merits of this Scheme the Chepstow Local Board has been empowered to carry it out, and last week the ceremony of cutting the first sod was performed by the chairman of the board. The contract was placed at £3500, the work to be executed within nine months.

**CONVALESCENT HOME FOR LEICESTERSHIRE.**—Plans of a building designed to accommodate some fifty patients, and capable of extension, are being prepared by an architect of Loughborough. The total cost, including purchase of site, water-supply and laying out of grounds, is estimated at £5000, a large part of which is already promised.

**HOSPITAL SATURDAY FUND.**—The report of the council of this fund, presented at the quarterly meeting of the board of delegates, held at the Drill Hall, Farringdon-street, last week, showed that the receipts up to Sept. 3rd amounted to £11,349 12s. 2½d. as compared with £10,481 15s. 5d. at the corresponding period last year. The street collection exhibited a large increase on former results.

**PRESENTATION.**—Last week the Mayor and Mayoress of Halifax, Yorks, held a reception, at which a testimonial in the shape of a portrait in oil, together with a silver tea service, was presented to Dr. Solomon C. Smith on the occasion of his leaving the town. The portrait bore a tablet with the inscription: "This portrait of Solomon Charles Smith, M.D., was presented to the Halifax County Borough Council by some of his fellow-townsmen, who wished to mark their sense of the great value of his many public services and their esteem for him.—Oct. 6th, 1892." The presentations were made by the Rev. F. E. Millson in a laudatory address.

**THE LONDON HOSPITAL MEDICAL COLLEGE.**—An old students' dinner was held in the library of the Medical College on Monday, Oct. 3rd, and took the place of the opening ceremony and introductory address, which have been discontinued for some years. The chair was taken by Dr. Langdon Down and about 150 old London men were present. Among the guests were Mr. Murray Ind, the chairman of the hospital, Mr. Carr-Gomm, Mr. W. J. Thompson, and many others who are concerned in the administration of the hospital. After the usual loyal toasts, "Prosperity of the Hospital and College" was proposed by the chairman, who enlarged upon the progress the institution had made within recent years and the numerous changes which had taken place in the methods of medical education. Mr. Murray Ind, who responded for the hospital, alluded to the admirable manner in which the hospital and college authorities had always worked together and to the pride and interest which were taken in the medical school. Mr. Hutchinson, in responding for the college, spoke of the improved conditions under which the work of the school was being carried on and of the vast additions which had been made to the building to meet the requirements of a modern medical education. He dealt especially with the elaborate arrangements which had been made to render perfect the department of public health, to the facilities available in the wards and in the college for practical teaching and to the establishment of the post of a medical tutor. He explained that this latter appointment had been rendered possible by the generosity of Sir Andrew Clark. After the dinner most of the guests retired to the museum, which was converted for the time into a lounging room. Much interest was shown in the new osteological gallery—a gallery in which selected marked specimens of the bones are so mounted upon special turn-tables as to be available for ready study.

## Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BASSANO, T. M., M.B., C.M. Edin., L.R.C.P. & S. E., has been appointed House Surgeon to the Huntingdon County Hospital.  
 BROCKBANK, E. M., M.B., has been appointed House Physician to the Birmingham General Hospital.  
 BURNS, R. J., L.R.C.P. Lond., M.R.C.S., has been appointed Police Surgeon for the Borough of Sunderland, vice Wood, resigned.  
 CAMPBELL, W. S., M.B., C.M. Glasg., has been appointed Medical Officer for the Crediton Sanitary District and Union Workhouse of the Crediton Union.  
 CONWAY, A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 2 Sanitary District of the Stourbridge Union.  
 CROSS, A. J., M.B., C.M. Edin., has been appointed Medical Officer for the Dalton Sanitary District of the Ulverston Union.  
 DRYLAND, LESLIE WINTER, M.R.C.S., L.R.C.P., has been appointed Assistant House Surgeon to the Northampton General Infirmary.  
 FOXCROFT, F. W., M.B., C.M., has been appointed House Physician to the Birmingham General Hospital.  
 GREEN, REGINALD, M.B., B.S. Durh., has been appointed Assistant Medical Officer to the Gateshead Dispensary.  
 HOSKINS, WM., M.B., C.M. Aberd., has been appointed Medical Officer for the Nazeing District of the Epping Union.  
 HEELAS, WALTER W., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician to the General Lying-in Hospital, Lambeth, S.E.  
 JAMES, W. E., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for the Abercarn Urban Sanitary District of the Newport (Mon.) Union.  
 LANCASTER, ERNEST LE CRONIER, B.A., M.B., B.Ch. Oxon., M.R.C.S., has been appointed Pathologist and Chloroformist to the Swansea Hospital.  
 LARKING, A. E., M.D. Durh., M.R.C.S., has been appointed Medical Officer for the Eighth Sanitary District of the Aylesbury Union.  
 NICOLL, JAS. H., M.B., C.M. Glasg., has been appointed Surgeon to the Department for Diseases of the Urinary and Genito-urinary Organs at the Glasgow Central (late Anderson's College) Dispensary.  
 NORTON, JOHN, M.D., D.P.H., has been appointed Medical Officer of Health to St. Peter's Close, Westminster.  
 ORTLEPP, A. J., M.R.C.S., L.R.C.P. Lond., has been appointed Senior House Surgeon to the Female Lock Hospital, Harrow-road, vice Dr. Kingston, resigned.  
 PARSONS, J. F., M.R.C.S., has been appointed Medical Officer of Health for the Frome Urban Sanitary District of the Frome Union, vice J. Parsons, deceased.  
 ROBERTSON, J. S., M.R.C.S., has been appointed Medical Officer for the Bloxham Sanitary District of the Banbury Union.  
 TWEDDY, R. C., M.R.C.S., L.R.C.P., has been appointed Assistant House Surgeon to the Birmingham General Hospital.  
 VINRACE, FELIX, M.D., F.R.C.S., has been appointed Surgical Casualty Officer to the Birmingham General Hospital.  
 WACHER, FRANK, M.R.C.S., has been reappointed Medical Officer of Health for the Canterbury Urban Sanitary District.  
 WARE, H. S., B.A., M.B., B.C. Camb., L.S.A., has been appointed House Physician to the City of London Hospital for Diseases of the Chest, Victoria-park, E.  
 WRIGHT, H., L.R.C.P., L.M. Edin., M.R.C.S., has been reappointed Medical Officer of Health for the Gainsborough Rural Sanitary District.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Medical Staff Vacancy.  
 BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary £150 per annum (with an allowance of £30 per annum for cab hire), and furnished rooms, fire, lights, and attendance.  
 BOROUGH OF KINGSTON-UPON-TYAMES.—Medical Officer of Health for the Borough. Salary £150 per annum.  
 BRISTOL EYE HOSPITAL.—House Surgeon. Salary £120, without board or residence.  
 CRICHTON ROYAL INSTITUTION, Dumfries.—Assistant Medical Officer. Salary £200 per annum, with board and residence.  
 DOVER HOSPITAL.—House Surgeon. Salary £100 a year, with furnished apartments, board, coals, lights, and attendance.  
 DEVON COUNTY LUNATIC ASYLUM.—Assistant Medical Officer. Salary £100, rising by an annual increase of £10 to £120, with board, lodgings, and washing.  
 GENERAL HOSPITAL, Birmingham.—Pathologist (non-resident). Salary £120 per annum.  
 GENERAL HOSPITAL, Barbadoes, West Indies.—Junior House Surgeon for three years. Salary £200 per annum and quarters. (Applications to the Secretary, General Hospital, Barbadoes.)  
 HENDON LOCAL BOARD.—Medical Officer of Health for the Urban Sanitary District of Hendon, and to the temporary Infectious Diseases Hospital for one year. Salary as Medical Officer of Health £140 per annum, and for attending the hospital patients (including medicines) £35 per annum. (Apply to the Clerk to the Board, Local Board Office, The Boroughs, Hendon.)  
 HUDDERSFIELD INFIRMARY.—Honorary Physician.  
 KIDDERMISTER MEDICAL AID ASSOCIATION.—Qualified Assistant, out-door. Salary to commence at £120 per annum. (Apply to Dr. Martin, Spring Bank, Kiddermister.)

LEEDS FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Assistant Medical Officer. Salary to commence at £120 per annum and midwifery fees. (Apply to Mr. Wilson, Incorporated Accountant, 8, South Parade, Leeds.)  
 MANCHESTER CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham-hill-road.—House Surgeon. Salary £80 per annum, with apartments and board.  
 NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Resident Medical Officer for six months, and Assistant Resident Medical Officer for six months. Salary for the senior post £50.  
 ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon for six months. Rooms, commons (exclusive of alcoholic drinks), and washing provided.  
 ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Resident Medical Officer for six months. Salary at the rate of £100 per annum, with furnished apartments and board.  
 SHEFFIELD SCHOOL OF MEDICINE.—Tutor, to take charge of Dissecting Room and hold classes in Anatomy and Physiology. Salary commencing at £100.  
 WALSALL COTTAGE HOSPITAL (Surgical).—Resident Surgeon. Salary £100 per annum, board, lodging, and washing.  
 WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—Medical Officer to the Provident Dispensary attached to the Hospital. Salary £60 per annum, with board, lodging, and washing.

## Births, Marriages and Deaths.

### BIRTHS.

ASHFORD.—On Oct. 8th, at Westbourne-park-road, Bayswater, W., the wife of Claude H. Ashford, M.R.C.S., L.R.C.P., of a daughter.  
 COLLINS.—On Aug. 11th, at The Residence, Peak Downs District Hospital, Clermont, Queensland, the wife of M. J. Collins, L.R.C.S. Edin.—J.P. (Surgeon-Superintendent), of a daughter (Eileen Violet Cope, land).  
 FRANCIS.—On Oct. 7th, at The Bulwark, Brecon, South Wales, the wife of George P. Francis, L.R.C.S., of a son.  
 GWYTHIER.—On Oct. 8th, at Upper Woburn-place, London, the wife of James Gwyther, M.B., of a son.  
 KEEGAN.—On Sept. 20th, at Indore, Central India, the wife of Brigade-Surgeon-Lieut.-Colonel Keegan, F.R.C.S., Residency Surgeon, of a daughter.  
 LEESON.—On Oct. 9th, at Clifden House, Twickenham, the wife of J. R. Leeson, M.D., F.L.S., of a son.  
 MARTIN.—On Oct. 5th, at Prudhoe-terrace, North Shields, the wife of A. Angus Martin, L.R.C.P.E., L.R.C.S.E., of a son.

### MARRIAGES.

BAYLOR—LOVELL.—On Oct. 5th, at All Saints', Kensington-park, W., Edward Arthur Crampton Baylor, B.A., M.D. T.C.D., of Ash, Dover, to Harriette Marianne (May), only daughter of Arthur G. Lovell, Cornwall road, Westbourne-park, W.  
 BEARDSLEY—WADDINGTON.—On Oct. 6th, at St. Paul's Church, Grange-over-Sands, by the Rev. Canon Cooper, Richard Henry Beardsley, L.R.C.P., L.R.C.S., E., &c., to Margaret (Mrs. W. E.) Waddington.  
 DAWE—MARTIN.—On Oct. 6th, at St. Paul's Church, Stonehouse, James H. Dawe, M.B., Surgeon R.N., H.M.S. Vernon, eldest son of the late J. E. E. Dawe, of Plymouth, to Minnie Florence, elder daughter of the late C. J. Martin, Paymaster R.N.  
 ELAM—MORRISH.—On Oct. 6th, at Christ Church, Sreatham-hill, George Elam, M.B., B.S., of Upper Montague-street, Russell-square, to Ethel Marion, youngest daughter of the late James Morrish, Clapham-park.  
 FOSTER—SHIPLEY.—On Oct. 11th, at the Parish Church, Tavistock, by the Rev. W. H. David, Michael George Foster, M.A., M.B., son of Prof. Michael Foster, F.R.S., of Ninewells, Great Shelford, Cambridge, to Charlotte, eldest daughter of the late General Reginald Younge Shipley, C.B. formerly of the 7th Royal Fusiliers.  
 HARRIS—HIGGINSON.—On Sept. 14th, at St. John's Church, Paddington, by the Rev. T. B. Clarke, B.D., Herbert Elwin Harris, B.A., M.B. Cantab., M.R.C.S., L.R.C.P., Medical Superintendent of the Infirmary, East Dulwich, to Edith, eldest daughter of the late James Pickford Higginson, Liverpool.  
 MABERLY—SMITH.—On Oct. 4th, at St. Martin's Church, Laugharne, Carmarthenshire, Ernest Maberly, M.R.C.S., fourth son of F. H. Maberly, late Assistant Surveyor G.P.O. (Exeter and Bath), to Hilda Gertrude, fourth daughter of the late Major S. Lionel Smith, 54th Regt., and of Milton Bank, Laugharne.  
 MATHEWS—DAWSON.—On Oct. 8th, at Clacton-on-Sea, the Rev. W. S. Mathews, B.A., LL.B., to Edith Frances, daughter of Major E. B. Dawson, of Tower Lodge, Clacton, and granddaughter of the late Wm. Kendall Dawson, of Fraying Hall, Gt. Bentley, Essex.  
 ORD—BILLINGS.—On Oct. 5th, at St. John's Church, Georgetown, D.C., William Walter Ord, M.D., M.A., Oxon., of 2, Queen-street, Mavfair, W., to Mary Clare, eldest daughter of John S. Billings, M.D., D.C.L. Oxon., of Washington, D.C., U.S.A.  
 RIMMEL—BULLOCK.—On Oct. 6th, at St. Mary's Church, Warwick, Alfred Tom Rimmel, Surgeon R.N., H.M.S. Alexandra, elder son of the late Dr. T. W. Rimmel, R.N., Hardley-crescent, Earl's-court, S.W., to Elsie, eldest daughter of T. W. Bullock, Esq., East Gato, Warwick.

### DEATHS.

LONGSTAFF.—On Sept. 23rd, at his residence, Butterknowle, Wandsworth, George Dixon Longstaff, M.D., in his 94th year.  
 SANDERSON.—On Oct. 9th, at Bridge-street, Musselburgh, Alexander Macdonald Sanderson, F.R.C.S. Edin., aged 60.

N.B.—A fee of 6s. is charged for the Insertion of Notices of Births, Marriages and Deaths.

# Medical Diary for the ensuing Week.

## Monday, October 17.

**KING'S COLLEGE HOSPITAL.**—Operations, 2 P.M.; Fridays and Saturday at the same hour.  
**St. BARTHOLOMEW'S HOSPITAL.**—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.  
**ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.**—Operations daily at 10 A.M.  
**ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.**—Operations, 1.30 P.M., and each day at the same hour.  
**CHELSEA HOSPITAL FOR WOMEN.**—Operations, 2.30 P.M.; Thursday, 2.30 P.M.; Friday, and Saturday at the same hour.  
**HOSPITAL FOR WOMEN, SOHO-SQUARE.**—Operations, 2 P.M., and on Thursday at the same hour.  
**METROPOLITAN FREE HOSPITAL.**—Operations, 2 P.M.  
**ROYAL ORTHOPEDIC HOSPITAL.**—Operations, 2 P.M.  
**CENTRAL LONDON OPHTHALMIC HOSPITAL.**—Operations, 2 P.M., and each day in the week at the same hour.  
**UNIVERSITY COLLEGE HOSPITAL.**—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.  
**LONDON POST-GRADUATE COURSE.**—Royal London Ophthalmic Hospital: 1 P.M., Mr. W. Lang: Lachrymal Affections.—101, Gt. Russell-street: 8 P.M., Dr. Galloway: Heart, Valvular Lesions.—Parkes Museum (Margaret-st., W.): 4 P.M., Dr. Louis C. Parkes: House Drainage.  
**MEDICAL SOCIETY OF LONDON.**—8.30 P.M. The President (Mr. Jonathan Hutchinson): On Names and Definitions in Disease. (Opening Address.)

## Tuesday, October 18.

**GUY'S HOSPITAL.**—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.  
**St. THOMAS'S HOSPITAL.**—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.  
**St. MARK'S HOSPITAL.**—Operations, 2 P.M.  
**CANCER HOSPITAL, BROMPTON.**—Operations, 2 P.M.; Saturday, 2 P.M.  
**WESTMINSTER HOSPITAL.**—Operations, 2 P.M.  
**WEST LONDON HOSPITAL.**—Operations, 2.30 P.M.  
**St. MARY'S HOSPITAL.**—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same day, 2 P.M.  
**LONDON POST-GRADUATE COURSE.**—Hospital for Skin Diseases, Blackfriars: 4 P.M., Mr. Hutchinson: Hybrid Forms of Skin Diseases—Bethlem Hospital: 2 P.M., Dr. H. Corner: Hypochondriasis.—101, Great Russell-street, W.C.: 8 P.M., Dr. Potter: Eclampsia.  
**PATHOLOGICAL SOCIETY OF LONDON.**—Mr. E. Hurry Fenwick: Two cases of Myxœdema treated by Injections of fresh Thyroid Juice—Dr. H. D. Rolleston: Specimens of "Fat Necrosis" associated with Disease of the Pancreas.—Mr. Edgar Willett: Two Specimens of Congenital Cystic Disease of the Scrotum.—Dr. Percy Kidd: Cirrhosis of Liver from Valvular Disease of the Heart.—Mr. Sydney Jones: Unstriped Myoma from Penis. Card Specimens.—Dr. Percy Kidd: Embolic Aneurysm of the Pulmonary Artery.—Dr. E. C. Perry: (1) Perforating Ulcer of the Duodenum; (2) Fatal Intra-pneural Hemorrhage in Pneumonia.

## Wednesday, October 19.

**NATIONAL ORTHOPEDIC HOSPITAL.**—Operations, 10 A.M.  
**MIDDLESEX HOSPITAL.**—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.  
**CHARING-CROSS HOSPITAL.**—Operations, 3 P.M., and on Thursday and Friday at the same hour.  
**St. THOMAS'S HOSPITAL.**—Operations, 1.30 P.M.; Saturday, same hour.  
**LONDON HOSPITAL.**—Operations, 2 P.M.; Thursday & Saturday, same hour.  
**St. PETER'S HOSPITAL, COVENT-GARDEN.**—Operations, 2 P.M.  
**SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.**—Operations, 2.30 P.M.  
**GREAT NORTHERN CENTRAL HOSPITAL.**—Operations, 2 P.M.  
**UNIVERSITY COLLEGE HOSPITAL.**—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.  
**ROYAL FREE HOSPITAL.**—Operations, 2 P.M., and on Saturday.  
**CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.**—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.  
**LONDON POST-GRADUATE COURSE.**—Hospital for Consumption, Brompton: 4 P.M., Dr. Percy Kidd: Examination of the Sputum.—Royal London Ophthalmic Hospital: 8 P.M., Mr. A. Q. Silcock: Various Ophthalmoscopic Cases.  
**ROYAL MICROSCOPICAL SOCIETY.**—3 P.M. Dr. C. E. Beever: Methods for Staining Medullated Nerve Fibres.—Mr. G. Maseee: Heterosporium Asperatum, a parasitic fungus.—Dr. H. G. Piffard: Notes on the Use of Monochromatic Yellow Light in Photomicrography.

## Thursday, October 20.

**St. GEORGE'S HOSPITAL.**—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.  
**UNIVERSITY COLLEGE HOSPITAL.**—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.  
**LONDON POST-GRADUATE COURSE.**—Hospital for Sick Children, Great Ormond-street: 4 P.M., Mr. J. H. Morgan: Vesical Calculus and its treatment.—National Hospital for the Paralyzed and Epileptic: 2 P.M., Dr. Beever: Paralysis Agitans and Tremors.—London Throat Hospital, Great Portland-st.: 8 P.M., Dr. E. Law: Examination of the Throat and Nose.—Central London Sick Asylum, Cleveland-st., W.: 5.30 P.M., Mr. Thomas Bryant: Surgical Cases in the Wards.  
**HARVIAN SOCIETY (Stafford Rooms).**—8.30 P.M. Mr. Lawson Tait: Peritonitis.  
**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.**—8.30 P.M. Patients and Card Specimens at 8 P.M. Mr. Henry Juler: Melanotic Tumour growing from the Ciliary Region.—Mr. W. M. Beaumont: Neoplasm (Sarcoma?) of the Iris.—Mr. Hartridge: A case of Double Neuro-Retinitis following Influenza.—Mr. E. Treacher Collins: Congenital Defects of the Iris and Glaucoma.—Mr. H. Work Dodd: The Optical Conditions of Fifty Persons suffering from no Ocular Disturbance. And other papers.

## Friday, October 21.

**ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.**—Operations, 2 P.M.  
**LONDON POST-GRADUATE COURSE.**—Hospital for Consumption, Brompton: 4 P.M., Dr. Percy Kidd: Examination of the Sputum.—Bacteriological Laboratory, King's College, 11 A.M. to 1 P.M., Prof. Crookshank: Cultivation of Bacteria (Cultivations).

## Saturday, October 22.

**UNIVERSITY COLLEGE HOSPITAL.**—Operations, 2 P.M.; and Skin Department, 9.15 A.M.  
**LONDON POST-GRADUATE COURSE.**—Bethlem Hospital: 11 A.M., Dr. Percy Smith: Melancholia.

## METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Oct. 13th, 1892.

## Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

### COMPLICATIONS OF SCARLET FEVER.

THE most common complications of scarlet fever in the hospitals of the Metropolitan Asylums Board last year were (giving the percentage of cases on the total number under treatment)—albuminuria, 8.5; otitis, 7.7; adenitis, 6.1; rhinitis, 4.8; diphtheria and diphtheritic condition of the fauces, 3.4; rheumatism, 2.3; and acute nephritis, 2.8.

*Dr. G. L. Johnson.*—No means have yet been discovered of opening the eyes of the public to the fraud of such "cures" or of punishing the authors of the advertisements, so long as they do not use titles which imply that they are registered practitioners.

*Mr. J. H. Straker* should consult articles in THE LANCET, 1892, Aug. 6th, p. 318, and July 23rd, p. 207, in which will be found all the information he requires.

*F. D. S.* wishes to be informed as to what degree it is necessary to possess before practising in Belgium.

### TERRITORIAL DISTINCTIONS.

To the Editors of THE LANCET.

SIRS,—I do not think Dr. Ormsby is quite fair in his complaint about the exclusion of Scotch and Irish diplomates from appointments at English hospitals. There is the other side of the question. Are English diplomates freely admitted to appointments at Irish and Scotch hospitals? I think not. There may be no rules excluding them, but such candidates are rarely, if ever, elected. Is there any physician or surgeon holding only English qualifications on the staff of any of the larger hospitals in Scotland or Ireland? If, then, it be the case that at the Scotch or Irish hospitals English diplomates are admitted as candidates but are rarely, if ever, elected, where is the "fair play" which Dr. Ormsby cares for? The English hospitals have, at any rate, the credit of being straightforward, since they will not admit a candidate whose qualifications are certain to be objected to.

I am, Sirs, yours faithfully,

Oct. 10th, 1892.

FAIR PLAY.

## OUR BREAD SUPPLY.

A CORRESPONDENT writes:—"Although much has been done of late years to improve the condition of our bakehouses and recent legislation has imposed new duties on medical officers of health with regard to them, it appears to me that one, and I may say a very important, matter has been overlooked. I refer to the condition of the sacks in which the flour is kept. I have often noticed the particularly dirty appearance of some of these sacks when full, and have come to the conclusion that no proper means are taken to cleanse them before they leave the mill for the bakehouse. Some millers, I believe, have a process for brushing the sacks; but is this sufficient? It is a common practice in some bakehouses in London for the men employed in the bakehouse to use the empty sacks as floor mats, and if anything is spilt on the bakehouse floor a sack is thrown over it. Most medical officers know the usual state of bakehouse floors. Surely flour must become to a certain extent unwholesome by being placed in filthy sacks, and I should like to call the attention of sanitarians, medical men and others to this matter, to see if some steps cannot be taken to ensure the delivery of flour to the bakehouses in, at any rate, wholesome sacks. I think this subject will be found interesting to many, and if ingenuity can be brought into action to invent a process for the thorough cleansing of the sacks it will be amply repaid."

*Mr. Isaac Westley.*—It is obviously right in ordinary cases to send for the practitioner in regular attendance. In emergencies, of course, it is legitimate to ask the nearest practitioner to attend.

*Lieut.-Colonel W. H. A.* (Junior Carlton Club) is thanked. We have alluded to the subject.

## GREEK AND THE M.D. DEGREE.

To the Editors of THE LANCET.

SIRS,—Under the new ordinances prepared by the Commissioners under the Universities (Scotland) Act, 1889, students who commence their studies before the date of the ordinances coming into effect may graduate under the old or new regulations. Under the old regulations it was necessary to take Greek before proceeding to the M.D. degree, but under the new regulations one may substitute a modern language, such as French or German. I think this is a very great boon, as for one boy who nowadays learns Greek at school dozens learn French and German, as being more likely to prove of ultimate use. At the present time there is a large amount of medical literature written in both of these languages, and many of us like to run over to Germany or France to see the practice of these schools. But there is a great anomaly, and it seems to me a great hardship to many others who, like myself, have passed the M.B. and C.M. Unless I am misinformed, an M.B. and C.M., under the old regulations, is not to be allowed to substitute French or German for Greek for his M.D. Why, I should like to know? We passed, it seems to me, quite as severe, and I believe a more extensive, examination in general education than is now asked at the preliminary. We had to pass in mechanics and also in at least two of the following subjects:—Greek, French, German, higher mathematics, natural philosophy, logic and moral philosophy; so that we had to take mechanics and one of these subjects as an extra over and above Greek, which was compulsory for the M.D. Under the new regulations mechanics is not required at all and only one extra subject, which may be Greek or German or French. I fail to see why one is less a student after he has taken his M.B. than before; but so the powers that be seem to make out, as we are not, I understand, to be allowed to graduate M.D. under the new regulations. Had we not passed our M.B. degree we could have graduated M.B. under the new regulations and ultimately M.D., but because we have graduated M.B. under the old regulations we may not take our M.D. under the new regulations—i.e., have the right to substitute German or French for Greek if we are so minded. As well as making the M.D. more attainable for new students and those old ones who have not graduated M.B. as yet, the old M.B. should have at least an equal privilege. Many of us have been in practice for years and would have graduated M.D. long ago had it not been for this bugbear Greek, and had we had the choice there is under the new ordinances. An appeal should be made by all M.B.'s to be granted the undoubted privilege of substituting German or French for Greek (as under the new regulations), and on passing one of these, one of the old extra subjects and writing a thesis to be allowed to graduate M.D.

I am, Sirs, yours faithfully,

Oct. 6th, 1892.

M.B. & C.M.

## "GOUT IN THE THROAT.

To the Editors of THE LANCET.

SIRS,—I shall esteem it a very great favour if you will kindly insert a question for me in your valued journal. What is meant by "gout in the throat"? I am unable to obtain any information on the subject from works at my command. Quite recently a patient of mine was told by an eminent physician that he was afflicted with it, when it turned out to be a bad "drain throat," followed by infiltration and suppuration of the cervical glands. The daily papers, too, have recently spoken of some distinguished sufferers from this malady.

I am, Sirs, yours obediently,

ALFRED W. GEORGE, M.B., M.R.C.S.

Burton-road, N.W., Oct. 10th, 1892.

## AN UNPLEASANT EXPERIENCE.

A CORRESPONDENT sends us an account of an unpleasant experience he recently had while bathing at Folkestone. He says:—

"As I intended returning to London by the 8.20 express in the morning, I went at 7 o'clock to have a final bathe opposite the Switchback, and after a considerable swim, and when not more than twenty yards from shore, I experienced a violent shock in the left forearm, which I can only describe as being like a brush of needles, instead of bristles, driven in with great force. I immediately suffered the most intense pain, and in less than ten minutes (before I had finished dressing) so virulent was the poison and so thoroughly impregnated was my blood that I experienced the most agonising pain in every part of my body. By the time I got home at, say, half-past seven, I was in a high fever, my veins standing out like whipcord, and the blood surging through them as hot water through the pipes of a high-pressure boiler, and the only way I can describe the torture was as if red-hot needles had been run into every vein of my body. A local chemist, to whom in my agony I applied, gave me a lotion to rub on the part, but I might have known it would afford no relief, as by that time I was in a raging fever, the poison having permeated my whole system. The only relief I found was in taking the most violent exercise, and I climbed at least a dozen times from the beach to the Leas. Let your readers should say it was a jelly fish, I may as well say that I have swam through shoals of them, and on the very visit to Folkestone I am describing was stung more than once, but then the effect was purely local and resembled more than anything a nettle sting, which passed away in an hour or so."

Supposing the statement of our correspondent to be correct in all respects and not an unconscious exaggeration—which, of course, is always possible—one would imagine that he was either peculiarly sensitive to the stings of the jelly fish, which at the time in question appear to have been more severe than those he had previously felt; or it may be that he was unfortunate enough to come in contact with a "Portuguese man of war," which is known to be far more virulent in its effects than the commoner jelly fishes. It is, however, unusual to see them round our coasts, except on the southern shores and in warm weather.

*Nineteen Years in Practice.*—The position is a delicate one. The more quietly practice is resumed and the facts explained the better. Any thing like a written or printed communication is to be avoided. Some of the patients must necessarily have drifted away and become the patients of other medical men, who are not to blame.

*Mr. W. G. W. Collins.*—A temperature of from 58° to 60° F.

## MEDICAL PRACTICE IN MEXICO.

To the Editors of THE LANCET.

SIRS,—I see that in THE LANCET of Sept. 3rd, 1892, with regard to practice in Mexico, you say that no examination is required. By Mexican law no person is allowed to practise medicine or surgery without having passed an examination conducted by properly appointed examiners. This examination consists of written papers and *visu voce* examination of cases in hospital thesis, and all must be passed in Spanish. This latter proviso may sometimes be relaxed. About a year ago I intended to try for a Mexican degree, and I wrote on the subject to the legal adviser of the firm I work for, asking how to proceed. He wrote me a long reply, in which he told me that it was quite useless my attempting to obtain a degree in Mexico city, as the examiners would pass no man not holding a qualification from Madrid, (?) Berlin or Vienna, but at the same time telling me I might obtain a degree in Zucatan or Mentereiz, if I got good letters to persons in authority. Practically in country districts one is not interfered with, as the so-called doctors (Mexicans) are themselves unqualified men. In town men arrange with a Mexican doctor to sign death certificates. In my particular case, as I am a doctor only to men employed on these works, I am let alone; but I have to keep on friendly terms with the town authorities and obey all sorts of peculiar rules and regulations.

I am, Sirs, yours truly,

R. F. HILEY, L.S.A., B.A. Cantab.

Zumgrango, Mexico, Sept. 10th, 1892.

P.S.—My legal friend (who, I may remark, is one of the first men in Mexico) also told me that if I attended Mexicans I was very likely to be sued if a patient happened to die, and even if I won the case I should be put to endless expense. I see my letter has rather spun itself out. Please put it down to the influence of the Spanish language, in which a letter terminates "I am, your humble, faithful servant, who kisses your hands."

## "BALDNESS AND ITS TREATMENT."

To the Editors of THE LANCET.

SIRS,—In a letter in your issue of Sept. 10th, referring to an annotation upon the above subject, attention is drawn to the value of the percuter in restoring the growth of hair. May I ask what the percuter is and its mode of application?—I am, Sirs, yours truly,

Oct. 10th, 1892.

H. W. S. W.

## OWNERSHIP OF PRESCRIPTIONS.

*Dr. Rentoul.*—1. It is obvious that a prescription belongs to the person who pays for it—viz., the patient. 2. We regret that we cannot find room for the letter.

"A CURIOUS INCIDENT."

To the Editors of THE LANCET.

Sirs,—No doubt many stories can be told of persons passing per rectum larger sums of money than they were supposed to have swallowed. Some years ago an anxious parent told my father that her son had swallowed a sixpenny piece. A day or two after he passed two sixpenny pieces, my father remarking that he had got good interest for his money. Can you inform me what happened in the case of a nobleman's son, who was so ill after swallowing a half-crown some years ago?

I am, Sirs, yours truly,

Plymouth, Oct. 10th, 1892.

J. ELLIOT SQUARE.

ERRATUM.—In our last number, on page 838, it was announced that the trustees of the late Mrs. Eliza Holmes had forwarded to the treasurer of the Royal Hospital for Children and Women the sum of £2500. The sum should have been £250.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Communications, Letters, &c., have been received from—

- A.—Messrs. Allen and Hanbury, Bethnal-green; Messrs. Arnold and Sons, London; Lady Atkin, London; Mr. Atkins, Paignton; Dr. Adam, Boston; Anti-vixen; A. B. C., London.
- B.—Dr. J. H. Bell, Bradford; Mr. A. Blair; Messrs. Burgoyne and Co., London; Mr. S. W. Black, Devon; Mr. E. A. Barton, Kensington; Dr. Robt. Barnes; Dr. J. H. NEWSPAPERS.—Western Morning News, Sussex News, Birmingham Gazette, Law Journal, Nottingham Guardian, Sheffield Independent, Newcastle Journal, Scottish Leader, Le Temps (Paris), Cycling, Lundee Advertiser, Yorkshire Post, Scotsman, Leeds Mercury, Liverpool Daily Post, Bristol Mercury, Local Government Chronicle, Weekly Free Press and Aberdeen Herald, Insurance Record, Windsor and Eton Gazette, Hertfordshire Mercury, The News, Reading Mercury, Mining Journal, West Middlesex Standard, City Press, Newcastle Daily Leader, Surrey Advertiser, Catholic Times, Food, Drugs, and Drink Review, Surrey Comet, North Wales Guardian, Guy's Hospital Gazette, Local Government Journal, Windsor and Eton Express, Llandudno Advertiser, Saturday Review, Galignani's Messenger, The Sunderland Daily Echo Times of India, Sunderland Herald, The Hotel, Pioneer Mail, The Urn, Sunday Times, Hampshire Post, Lincoln Gazette, Guernsey Advertiser, Haddington Advertiser, Builder, Electrical Review, Architect, &c., have been received.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 Six Months ..... £0 16 8

TO THE CONTINENT, COLONIES, UNITED STATES, INDIA, CHINA, AND ALL PLACES

ABROAD ..... One Year 1 14 8

\* In consequence of the new postal arrangements, the Annual Subscription for India, China, and all foreign countries will now be reduced to £1 14s. 8d., instead of £1 16s. 10d. as formerly.

Post Office Orders and Cheques should be addressed to The Publisher, THE LANCET Office, 423, Strand, London, and crossed "London and Westminster Bank, St. James's-square."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only a ready means of finding any notice, but is in itself an additional advertisement. Advertisements (to ensure insertion the same week) should be delivered at the office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Canmartin, Paris.

## An Address

ON

## SYMPTOMS IN PERSPECTIVE.

*Delivered before the North London Medical and Chirurgical Society on Thursday, Oct. 20th, 1892,*

By SIR WILLIAM SAVORY, BART., F.R.S.,

CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL AND TO THE GREAT NORTHERN GENERAL HOSPITAL.

GENTLEMEN,—Allow me, before I proceed to the subject of my short paper, to congratulate you on the prosperity and progress of this Society. It is, perhaps, somewhat late in the day to discuss the advantages of such a Society as this, yet I venture to doubt if it is estimated at its full value by many even of its members. We should all agree, I take it, that great benefits are conferred by it, not only on those who belong to it, but throughout the profession. Every profession has its advantages and defects. The chief advantage of ours, in one respect, is its independence—the ample scope it gives for liberty of thought and action. We are conspicuously free to say and do what we deem right. “Doctors differ” should be, when properly understood, no term of reproach, for it means that the different views of doctors are so apparent only because they are very freely expressed. Medicine and surgery are not more uncertain than theology and law, but the uncertainties are more constantly and openly acknowledged. Now I think this is an advantage; but there is also a defect. As our thoughts and opinions are not regulated or controlled, so we greatly lack any formal bond of common union. We are as a body too loosely knit together. In one sense we should be stronger, in another happier, if as a profession we were more closely bound; and I think that a Society such as this goes far to supply the want, and that therefore in this respect it has signal value beyond all the encouragement it gives to work and the facilities it affords for the publication of it. But it has another claim, and a wide one. I for one often feel the force of the objection which is taken to the ease and rapidity of publication. I cannot help sometimes thinking that we should be better off if a wiser care and stricter selection were exercised over what is called our literature. A free press is not always an unqualified blessing. But I observe that almost all the evil comes from a particular, and that a very limited, quarter. Comparatively few make all the noise. On the contrary, the great body is perhaps too silent. While on the one hand sound is too often a sign of emptiness, on the other what wealth of information, what a mine of knowledge must exist unrevealed! A Society like this, then, has, I conceive, its chief purpose in encouraging those to speak who ought to be attentively listened to. It ought to be the means of bringing to the surface much useful knowledge which but for it might never appear; and in this direction there is one point further to which I would allude. It has always seemed to me admirably adapted to the character of very much of our knowledge—to the growth and development of that kind of knowledge with which we have to deal. I think that the history of medicine shows that the truth we reach is wont to emerge only very slowly out of error and confusion. In its earlier stages it is not a thing to fix and formulate, but to discuss and criticise; and the principles we endeavour to establish are not, perhaps cannot be from their very nature, final ones. Of our work, beyond all others, it may be said that the goal of to-day is the starting-post of to-morrow; and so at least very much of our knowledge may be called floating knowledge. It is not fixed and crystallised, but is uncertain and constantly shifting. Now it is with knowledge of this kind—this mixture of half truths with much error and with more confusion—that our societies are particularly well fitted to deal, for here it is thoroughly criticised and discussed. It is considered from various points of view, and the chaff is winnowed from the grain. We are often reproached, and not without justice, with the kind and degree of evidence we are too disposed to accept; but this to a great extent is inevitable to the nature of the inquiry we are engaged in, and the mischief is largely corrected when it passes through the ordeal of an evening's discussion. And, finally, a society like this brings out not only strength on the intellectual side, but surely it does good work also on the moral side. This may not be the most prominent, but I

No. 3608.

venture to think that it is very far from being one of the least of their functions, and in this they discharge a duty which cannot be so easily handled elsewhere. Those of equivocal character and antecedents they may even reject as members, and in every well-regulated body none but those whose career is without stain or reproach can be elected to high office. On the other hand, they have the enviable privilege of placing publicly the stamp of professional approval on noble lives and worthy work. This great moral influence which our societies are especially fitted to exercise, who shall measure it?

And may I pause a moment here to pay a passing tribute to the memory of Le Gros Clark, who was, you know, a member of the staff of this hospital? In the death of Le Gros Clark the profession has sustained a severe loss—a loss far greater perhaps than may appear to many who did not know him well; for although the singular charm of his courtesy was appreciated by all his friends, some of the finest qualities of his nature were only reached by those who had the privilege of close and constant intercourse. It was my good fortune to have been intimately associated with him for many years as an examiner at the College of Surgeons, and so I came not only to admire his attainments, but to hold him in very high esteem. That he was not only a distinguished surgeon and a very wise and safe one, but a man of wide general culture, will be admitted by all. He had read and thought much, enjoyed good literature, and was deeply interested and well versed in the scientific questions of the day. His sympathies were always with the higher and nobler views, and he strove to raise the thought and tone of his profession. To regard surgery as a mere art he believed to be a very inadequate expression of it; scientific surgery was his aim, and his thought and work were ever in this direction. This careful culture of his mind and its constant exercise upon the higher lines of thought were evident in a remarkable refinement, and to this was added the attraction of great modesty and deference to the judgment of others, even of those far beneath him in power and attainments, which in the practice of his profession sometimes became almost weakness. He was singularly conscientious. This was carried so far as to lead frequently to indecision, which detracted from the weight, if not the value, of his opinion on difficult questions in surgery. He was apt to hesitate and qualify when a more ignorant man would have greater influence with others by more direct and confident assertions. This distrust of himself and deference to the opinion of others, with perhaps dislike of grave responsibility, may go some way to explain how it was that Le Gros Clark, although very eminent as a surgeon, never occupied the place in professional and public estimation to which he was entitled. But he had little regard for popularity and cared still less for the fruits of it. He valued far more the place he occupied in the esteem and affection of his friends. His ideal was a lofty one, and by this standard he always tried himself. He was from first to last a thorough gentleman, simple and sincere, pure and upright in word and deed. And now to the proper subject of my paper.

## ON SYMPTOMS IN PERSPECTIVE.

Everyone knows that the various symptoms of disease and injury possess very different degrees of importance; that they differ widely in value to the surgeon. For instance, as symptoms of calculus in the bladder the frequent presence of blood in the urine has a much higher value than abnormal frequency of micturition. In the diagnosis of fracture of the neck of the femur shortening is of more importance than eversion, and as evidence of acute inflammation rise of temperature is far more trustworthy than pain. And everyone knows, too, that the diagnosis of a case usually depends on an assemblage of symptoms, no one of which may be in itself very strong, but which in conjunction with others may mean much. For instance, neither a rigor nor an attack of sweating, nor a rise of temperature by itself or in association with certain other symptoms, may be significant of septicaemia, but a rigor followed by profuse sweating and associated with a high temperature occurring for the first time at a certain period after the infliction of a wound is indeed very strong evidence of the occurrence of blood poisoning. Again, as evidence of disease of the hip-joint in childhood, neither lameness nor stiffness of gait is by itself very strong, but a combination of these two signs in a child, with a history of their gradual onset and perceptible progress, followed by alteration of form, points very clearly to the disease in question. Once more, neither change of colour nor decline of temperature nor loss of sensibility is by itself of much

R

value as evidence of mortification, but an association of these three is strongly suggestive of impending death. But furthermore, symptoms are sometimes in apparent contradiction, and then more skill and judgment are required to appraise their relative significance. For example, how often are the characters of tumours apparently discordant in evidence of their nature? A tumour in the neck or elsewhere may be hard enough for cancer, yet so painful, tender and hot, with superficial redness, as to suggest strongly the result of inflammation. Or a tumour in the breast may present some of the more obvious of the physical characters of scirrhus; yet if it occur in a young woman, an element of doubt is introduced into the case. Or again, suppose a smooth, uniform, fluctuating tumour in the scrotum, which is not translucent. Is it a hydrocele? The contradiction here must be resolved by further evidence. In syphilis also how often are the characters of the disease presented at the time of examination at variance with the history given of the case. And here is an illustration of the pitfalls which may beset the surgeon on either side. The more experienced men will usually, and for the most part justly, with confidence in their ability to judge correctly from what they see, ignore that part of the history which seems in contradiction to the facts before them. Yet, by the too rigid practice of disbelieving all that is not in harmony with their own fixed ideas, they may become confirmed in false doctrines, while younger men with conscientious zeal for knowledge, by attaching too much importance to what they are told and too little to what they see, may be led into confusion or error. Again, the obscurity which besets the nature of so many cases of intestinal obstruction is no doubt largely due to the fact that with our present knowledge we are not able to appraise even the absolute, and still less the relative, value of many symptoms which are apparently in contradiction. But of all classes of affections none illustrate so forcibly the diversity and opposition of symptoms as those which are called hysterical. In some of these cases all the resources of the surgeon are severely taxed in the endeavour to form an accurate and complete diagnosis, and perhaps no cases in surgery demand greater delicacy of judgment in diagnosis than those in which a hysterical or neuralgic state is engrafted on some actual mischief. The difficulty is not in forming a decided opinion and acting on it, even perhaps to the patient's advantage, but in estimating at their proper value the several symptoms that arise and reconciling them with a sound view of the nature of the case.

So, then, each of the symptoms which present themselves in any given case is to be regarded not so much in its absolute value as in its relative significance. The true meaning of any particular sign is not to be reached by considering it alone, but by viewing it in relation to the rest. No doubt it sometimes happens that a single symptom may have a value which outweighs that of all the others put together; but, even then, this will be made all the clearer by comparison, and it is in such instances especially that the importance of being able to estimate the relative value of the several symptoms is most plainly seen. So that as surgeons by observation and reflection become more skilful they learn to place the symptoms which present themselves in any given case in their proper relative position, and in taking measure of the proportion of each they learn to form a mental picture of the actual state of things. Certain signs are brought into the foreground; others are put back into the distance. In short, what the rules of perspective are to the artist this sound judgment of the relative proportion of symptoms is in surgical diagnosis. And thus it comes to pass that at length in many cases only a few points in each are taken much notice of. Many features, which to those less conversant may seem to be of great importance, are unheeded. Take, for example of this, a case of strangulated hernia. A surgeon familiar with his work will listen to the complaint of pain and general distress. He will of course note the condition of the abdomen, the character of the pulse and so on; but he will grasp at once the two great facts of vomiting and a tumour in the inguinal region, and from these he will promptly decide on his course of action. Nor will he be led to falter in his decision of the necessity of giving immediate relief to the strangulation by statements that the patient is too weak to bear an operation or that the sickness is less urgent than it was an hour or two since. He understands the relative value of the several symptoms and knows how to assign to each its due degree of importance. But it is not always thus with a surgeon who is strange to

the work. He too sees that there is sickness and ascertains the existence of a tumour; but he learns that the tumour is not tender, that the patient himself attaches no importance to it, states carelessly that it is of long standing, and has not altered for years; that the pain is in another part of the abdomen; that he is too weak to bear an operation, and would be stronger, he is sure, if he could have a little previous rest; and so on. Then, on pondering over the case, the doctor comes to give undue importance to the many reasons which appear to tell against an immediate operation, and he allows these to outweigh the two or three which should have been decisive.

I know of nothing which marks more plainly the different degrees of excellence of different surgeons than this ability of estimating the value of symptoms in their relation to each other. It is the natural fruit, and can be the fruit only, of work at the bedside. In spite of the nonsense which is often talked about theory and practice, we know very well that it is not always the man who can discourse most learnedly upon disease that can deal with it most ably when it is brought before him. And I believe that comparative failure in clinical work lies chiefly in this direction. A man may know what to look for and how to look for it; he may investigate a case thoroughly and scientifically and yet, by the very multiplicity of the facts which he has elicited, he may be drawn into error. He has plenty of subject for the picture he has to form, and the effect should be consistent and satisfactory; but he breaks down in the disposition and arrangement of his material; he has no skill in grouping the several objects; everything is too much on the flat; there is no depth of space in the landscape, and the result is either a false idea or mere confusion. But although the ability to judge correctly of the relative significance of symptoms is in practice of paramount importance, yet out of the confidence which comes of the long-continued use of it evil may arise. If the habit of seizing on certain symptoms only for guidance in diagnosis and treatment become too much a matter of routine, mistakes, and perhaps serious ones, will occasionally occur. Signs neither usual in a particular case nor prominent may be neglected, which nevertheless, if carefully considered, might materially modify or altogether change the view taken of it, and this perhaps is most likely to occur in cases which appear to be clear and free from all doubt. Where neither the nature of the case nor the proper treatment is at once obvious the sound plan of making a thorough examination throughout is the best safeguard against such errors; and even in the clearest and simplest cases it is always well, as a matter of precaution, to supplement our diagnosis by a general investigation such as this. Such a course can hardly ever be amiss, and even if nothing more should come of it a thorough and complete examination will be always useful to ourselves as a matter of discipline.

Hence a chief source of the weakness of specialism, as it is called. By the too exclusive devotion of attention to a particular part or subject symptoms which are elsewhere revealed may be either overlooked or ignored, or, if recognised and considered at all, are in danger of being relegated to the background in the presence of others which point in the direction to which the practitioner is accustomed to look. Anyone with such a restricted view works, as it were, in blinkers. He can see only within the limits of a narrow space; he is unable to look around. The defects of exclusiveness are perhaps too often seen even in physicians and surgeons. A patient may have two ailments, one of which falls within the scope of the former, the other of the latter. It may be said that it is but natural that the surgeon should give more heed to the one and the physician to the other. But is there not danger from this want of comprehension that neither will be able to do justice to the claims of both?

Errors in diagnosis and practice may be arranged under two heads; those due to ignorance and those due to carelessness; and very many, no doubt, are the result of the two causes combined. Consciousness of one's ignorance may do much to avert the errors of carelessness, and he who has confidence in his own judgment should be of all men most careful in inquiry. It may be truly said that in the examination of a patient, or in the notes of it, a man will often disclose much more of himself as a surgeon than of his patient's case. An inquiry may be very full and complete, and yet the result may be confused or obscure from the absence of all proportion in the adjustment of symptoms. Or, again, the salient points of a case may be at once detected, and yet the view taken of it may be

defective through the neglect of subordinate yet withal very significant features. In short, an examination of any given case can be regarded as satisfactory only when all the symptoms that can be elicited are carefully considered and then duly estimated according to their relative value.

It may be observed that in the foregoing remarks I have assumed the existence of the symptoms I have spoken of to be matters of fact. I have spoken of them as real and actual because I could state the case more clearly and make my meaning plainer in this way. But of course in one sense everything depends on the reality of symptoms. I need not dwell on the distinction between real symptoms and feigned ones, nor upon the well-worn and hackneyed division of objective and subjective symptoms. Accuracy of observation is an art to be acquired only by education and practice; and accuracy of statement is an art, too, to be acquired only by education and practice, dependent often upon accuracy of observation, but by no means always associated with it. Hence the need of long and careful training on the part of the student and surgeon before he can become sufficiently skilful and trustworthy in this respect, and hence the error into which patients of all persons are liable to fall. For most of them not only lack the education and training just spoken of, but, being the sufferers, the impulse to over-statement and exaggeration is naturally very strong. Every surgeon of course in some measure understands this and allows for it, and so of course attaches far greater importance and value to the symptoms which he can ascertain for himself, and which are called objective, than to those the existence of which he can learn only through the statement of the patient, and which are termed subjective. Yet a great, if not an equal, danger besets the surgeon here on either side. He stands, indeed, on firm ground in the presence of objective symptoms, but if so assured he comes to ignore the subjective ones, he may be led into serious error. A man who had previously suffered from gout in the form of phlebitis and in other ways gradually became jaundiced, while a tumour which everyone recognised as a distended gall-bladder presented itself. Weakness and emaciation gradually increased, but his chief complaint was of constant, dull, but severe pain in the back. The case seemed tolerably clear to most who saw it, and more than once it was proposed to open the gall-bladder. But he died without an operation, and after death malignant disease of the pancreas in an advanced stage was discovered, which had not been suspected during life; no disease of the liver, and only a few small gall-stones in the bladder, none of which were impacted. The objective symptoms were so marked that they and the persistent and severe pain in the back were referred to a common cause, which was believed to be confined to the region of the liver. Subjective symptoms cannot for the most part be compared with objective ones, but sometimes—and this perhaps is too often the case with the most experienced men—they are cast so far into the distance as to be lost sight of altogether. We depend most on what we can ascertain for ourselves by sight, hearing, touch, and so on, for here we have to do with facts and can, comparatively speaking, accurately measure them; while the others are not only of uncertain dimensions, but vague and obscure in other ways, especially in relation to our present knowledge, or rather our ignorance, for we are far less skilful in their correct interpretation.

The uncertainty of medicine and surgery! Yes; our knowledge and practice are uncertain enough truly—not more uncertain than many other studies, not so uncertain as some of them, I repeat. But we do best not in excusing or explaining this, which can easily be done, but by working with the view of erasing the reproach. And in this, indeed, in looking back over recent years, we may be of good cheer, for the great progress of medicine and surgery has been by the application of more exact methods and instruments of research; facts have been more industriously and thoroughly sought for and their existence and value subjected to a more rigorous and searching criticism. Theories and speculation and guesses are being superseded by more scientific methods of inquiry. Sciences more exact in themselves, such as physics and chemistry, have been brought, by the advance of a sounder physiology, into closer relation with medicine and surgery, while pathology, the lineal descendant of these, is springing into new and vigorous life. Yes; the issues of our work at the bedside are still uncertain enough, but look at the progress of recent years, and think of what it means for the time to come.

## Hunterian Lecture

ON

### ABSORPTION IN RELATION TO PHYSIOLOGY, PATHOLOGY AND THERAPEUTICS.

*Delivered before the Hunterian Society, Oct. 12th, 1892,*

By ROBERT BARNES, M.D., F.R.C.P. LOND.,  
F.R.C.S. ENG.,

CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—When I received from Mr. Poland your invitation to address you I am afraid I too hastily assented. I was attracted by the force of old associations, by a desire to revisit the arena of former work, and to renew pleasant intercourse with old friends. Had I waited to reflect that I was expected to bring with me an address worthy of my audience I should have adopted the wiser course and not have come. Not only is the choice of a subject difficult, but, when chosen, to treat it in a manner worthy of the occasion, is more difficult still. However, being committed to the task, if you should feel disappointed in your expectation of instruction or entertainment, I can only submit that you have brought the infliction on yourselves. But I feel sure that, if I cannot appeal to your judgment, I may with confidence rely upon your generosity. It is useful from time to time to revert to first or fundamental principles in studying the mode of action of nutrient, medicinal and toxic agents on the system. To pursue this study with any approach to fulness would require many addresses, and I fear that even the one I have rashly undertaken will be a heavy tax on your patience. In recent times great advances have been made in extending the methods of bringing the system under the influence of nutrient and medicinal agents. We are no longer so limited in practice as formerly to the simple method of introducing medicines into the stomach. Every part, every tissue of the body has been made use of as a route of entry or discharge. Indeed, whether we will or not, all those surfaces which are in direct contact with the atmosphere are in constant use as routes of entry or of exit—that is, of exchange of elements, useful or noxious. Although we are never free from the influence of atmospheric pressure, we know that this is nearly always uniform. The pressure upon the external surface of the body is counterpoised by the pressure upon the lungs. On the other hand, the relative pressure upon the heart and bloodvessels and the lymphatics and other tissues of the body is constantly varying, and according as the pressure changes from the one side to the other, exudation and absorption change. Artificially, again, almost every internal tissue of the organism may also be made the medium for introducing foreign agents into the system. This is now familiar enough, and so no doubt is much that I am about to say in relation to my theme. There are physical laws so familiar, so intimately linked with our habit of thought, that we are apt at times to fail to trace or fully to appreciate the part they play in the living work before us; and still more are we apt to fail in calling these forces to our aid when seeking to restore or to preserve that happy equilibrium of all the functions which is physiology in perfection, and when we essay to assist physiology in her contest with intercurent trials. I do not say that we shall try to counteract pathology, for pathology is simply physiology under difficulties. I say that all the surfaces and almost every tissue in the body may be the medium for the entry of nutrient and noxious elements into the system. But there is a correlative fact not so generally remembered upon which I wish more especially to insist. This is that we may often chase and control noxious elements through the same routes. A wider theme could hardly be chosen. It embraces the whole science of medicine. One may easily fall into disconnected discursions. I shall therefore limit myself as much as possible to some illustrations and reflections that flow from my personal experience.

Let me start with one or two general propositions on the phenomena of absorption. I will not attempt a task beyond my powers, that of tracing the action of the several tissues and vessels in absorbing and carrying elements from without

into the system. I will content myself with affirming my belief that all the powers these structures are, credited with are but examples of physical laws. Take one illustration from meteorology: When the air is saturated with moisture, as indicated by the dry and wet thermometers marking the same temperature, or by a bit of seaweed having absorbed the utmost amount of moisture it can take up. There we see one of the physiological forces under which the living body exists. This is the hygrometric state of the air, constantly varying in its relation to the body. Another force is that of atmospheric pressure, also varying, and yet in constant action. These conditions are both within certain limits under our command, and may be called in to the aid of the physician. Through this law of atmospheric pressure we may understand the phenomenon of hunger and thirst. Everyone knows what a vacuum in the stomach means. It is as true as the Torricellian vacuum. This is a fundamental condition of absorption.

Before going further I may state parenthetically that the art of modern hygiene consists in the application of the laws of physics to the preservation of health. The progress of medicine rests upon the right understanding and application of the same laws; and this study is only to be successfully pursued by the scientific observation of nature in her universal relations. If the day shall ever arrive when these laws of physics shall be universally recognised and applied to secure the good of mankind, we shall have attained that millennium when medicine, whose function, as long understood, was simply the art of curing diseases, or the accidents that afflict mankind, will have for its chief, if not only, function to prevent disease. The main obstacle we have to fight against is the prejudice that is born of ignorance, and that strives to perpetuate ignorance by erecting arbitrary barriers against the advance of knowledge through the observation of nature by experiment. In intimate and constant connexion with the processes of absorption and effusion under varying conditions of pressure, centripetal and centrifugal, we must not forget the influence of the law of diffusion of gases and liquids, and especially that of capillary attraction, which last is not immediately under the power of the heart and arteries. The two greatest masters of science to whose teachings I—and I may with just confidence add those who have come under my care as patients and students—I am most deeply indebted are Magendie and Marshall Hall. I name these two not because they stand alone, but because it was my especial good fortune to be their pupil. To Magendie I owe my first and enduring proof of that great truth which lies at the root of the theory of absorption. His experiments are quoted, or ought to be in every text-book of physiology. I allude to those in which having injected water into the veins of a dog, poison being administered subcutaneously, immediately before or soon after, it was found that the poison was absorbed and acted very slowly; whilst after bleeding it acted very quickly. An artificial thirst, acting like a vacuum, was created, attracting the poison rapidly into the circulating system. When I was a student in Paris bleeding was largely, no doubt empirically resorted to. Bonillaud especially I remember. His bleedings upon patients often exemplified the lessons taught by Magendie's experiments. I also remember that one of the physicians at St. George's Hospital when I was a student bled very freely. When I was an apprentice in the country the surgery was invaded every market-day in spring by farmers, who came to be "blooded." I have "blooded" four or five in a morning. Perhaps it did little good, but I do not know that it did them any harm. They soon made good the loss by absorption. They probably lost some more or less noxious elements, and certainly they were relieved of plethoric excess, and what they absorbed was, excepting perhaps too much brown stout, wholesome. In recent times bleeding has become obsolete, or nearly so. But we still have the instructive opportunity of witnessing the effects of what may be called physiological and accidental bleedings; and if the opportunities thus afforded be carefully observed by the light of Magendie's experiments we may witness similar proofs of the influence of depletion of the circulating fluid in promoting absorption. And now I may add that I have seen reason to regret that the lancet has been thrown out of the armamentarium of the physician. It is urged by the modern school that venesection is no longer useful because the constitution of mankind has altered. I will not contend that this argument or assertion is altogether unfounded; but of this I am convinced, by clinical and physiological observation—that in some cases the loss of

blood artificially or spontaneously brought about is a potent factor in the cure of disease and in the recovery of the system, under severe physiological trials.

Let me give an illustration from the history of pregnancy; and I take the opportunity of repeating what I have often insisted upon—namely, that the intelligent observation of the pregnant woman will reveal a series of vital and physical phenomena, equivalent in scientific value and as suggestive of useful practical application as many well-designed experiments. In fact, we may look upon pregnancy as a great physiological experiment. I will pass by the exalted nervous tension and other nervous phenomena induced—I made this the theme of my Croonian Lectures at the Royal College of Physicians—in order to fix attention more especially upon our actual text: absorption and some allied phenomena. During gestation there is a greatly increased formation of blood, tending to high vascular development and tension and even hypertrophy of the heart. There is what I have ventured to describe as extreme "physiological plethora." This condition is adverse to absorption. It is not indeed an absolute or trustworthy safeguard against zymosis, but I believe that it is to a certain extent protective. The predominant force of the circulation in pregnancy is constructive and excentric, disposing to exudation and hæmorrhage. Of course this work demands material for the construction, and therefore involves absorption. But still the preponderance of energy is from the centre to the periphery. The "physiological plethora" makes itself manifest in many ways. We not seldom witness hæmorrhages from the nose, the lungs, the stomach and the intestines. These hæmorrhages are evidence of the effort of nature to relieve the vascular tension. May we not say that they are significant indications to the physician? Can nature speak more plainly? She tells us to do what she is compelled to do—she bleeds. The difference is this. A physiological hæmorrhage once started is not easily arrested. It is too apt to run to excess, even to a fatal result, and this not only because the bleeding surface is not always under our control, so that we can stop the hæmorrhage at the right moment, but because the organ from which the bleeding proceeds will not tolerate the injury inflicted upon its structure. I well remember the case of the wife of a medical friend many years ago, who being three or four months pregnant and of plethoric habit, was seized with apoplexy from hæmorrhage in the brain. Abortion, with hæmorrhage also set in, but too late to save her. Two reflections forced themselves upon my mind. The first was that a timely venesection might have saved her. The second was that had the abortion occurred earlier she might have been saved by this event—one usually regarded as a calamity. Experience has convinced me that abortion is often an example of the *vis medicatrix nature*. It is often a conservative process, acting in regulating the circulation, bringing down the excessive turgor within healthy physiological bounds. Is not the lesson obvious that the physician should on proper indications obey the teaching of nature and bleed beimes? In Italy not many years ago I observed that pregnancy alone was still a sufficient reason for bleeding. Of course this, as a common practice, is an irrational, even barbarous, submission to prejudice and custom; but we have now gone to the opposite extreme, which I venture to think is hardly less irrational. I have had reason to congratulate myself that in some threatening cases I have had the courage to bleed; and, on the other hand, I have seen reason to regret that this powerful and safe operation had been neglected. The sphygmograph and subjective symptoms indicating excessive vascular fulness and turgor will supply the indication. In some cases of eclampsia it has undoubtedly done good whilst waiting for the response to the means employed for the induction of labour.<sup>1</sup> The effect of loss of blood and of abstinence from food is similar. Almost as soon as the stream begins to flow there seems to be a transudation of watery fluid from the tissues into the current of blood; it is drawn in to fill the vacuum. To a certain extent purging may take the place of bleeding. As a mode of depletion its action is similar, but it is far less prompt and efficacious.

Now we come to labour at term. At the moment of labour all is changed. There is probably no experiment in nature or in the laboratory so full of instruction as that seen in the sudden revulsion which follows upon labour. The nervous tension at once falls; the need for the physiological plethora ceases. The first step taken towards the restoration of the

<sup>1</sup> In one case I gave the blood to Professor Bernays to analyse. He found in it urea and uric acid.

ordinary physiological equilibrium is marked by the loss of blood. The natural limit of this loss may be taken to be the discharge of that quantity which is in excess of what is required for the mother's need—that is, of the quantity which had been provided for the development of the embryo and of the maternal structures concerned in the process of childbearing. But the discharge of blood is really—to say nothing at present of extraordinary hæmorrhages—in excess of this. The loss is enough to cause at once what may be regarded as a degree of vacuum in the system; and the consequence of this is almost immediate. A process of active absorption at once sets in. The work to be done is one of demolition and of removal of the tissues, and fluids used in the process of construction now become superfluous. In the first place there is a large amount of fluid, serous chiefly, which had been effused in the broad ligaments and in the cellular tissue of the pelvis, and often throughout the cellular tissue of the body and limbs; this is taken up very quickly. Secondly, there is the excess of more or less solid matter in the uterine walls, in the specially developed bloodvessels and lymphatics and in the heart; this matter undergoes first a degree of fatty conversion and liquefaction. In the third place there sometimes occurs, unhappily, absorption of decomposing blood, of necrotic tissue resulting from the injuries sustained in labour, and of other noxious matter, chiefly from the uterus. This constitutes what I may call endogenetic toxæmia, or simple puerperal fever. This is enough without the absorption of poison from without. When this occurs there is the heterogenetic toxæmia added to the endogenetic. This view is, I believe, now generally accepted. Like the simple endogenetic form it is largely due to the increased activity of absorption caused by hæmorrhage; but there is one important point to remember in this association. It is that the poisons taken in from without include all the zymotic poisons, malaria of all kinds, the septic poisons from filth; and that when one of these is taken in it has to meet the endogenetic poison already in action or, if not in action, quickly brought on. We thus have a compound toxæmia, not always, I think, represented by the two original poisons, each acting in its own way; but probably a greater complication, resulting from the interactions of the two, generating a compound more dangerous than either of the two out of which it sprang. One observation I have often made which leads to this hypothesis is that in the case of a zymotic, as scarlet fever, the ordinary characters, as witnessed in the non-pregnant subject, are so changed or overridden that the simple zymotic is not always recognised. The same thing occurs with small-pox. It is when small-pox seizes the parturient woman that it is especially apt to take the hæmorrhagic character. There is a remarkable fact in this connexion as bearing on absorption. It has been observed by Braxton Hicks, by myself and by others that, although a woman may have been exposed for months continuously before labour, still the zymotic disease does not generally manifest itself till the third, fourth, or fifth day after labour. This suggests the question, Does the poison lie dormant until labour, when the arterial tension is lowered, and active absorption brings a rush of waste-matter into the blood; or does the plethora of pregnancy really act as a protection against the entry of the poison, warding it off?

Pardon me another digression. It was said—I believe by no less a man than John Hunter—that two poisons could hardly exist together in the same subject. “*Haud bene conveniunt nec in unâ sede morantur.*” Many years ago I published a case in which it appeared to me that a child had absorbed the poisons of small-pox and scarlet fever. There was evidence that the patient had been exposed to both poisons, and then that small-pox had been communicated to one person and scarlet fever to another. Notwithstanding cases of this kind we cannot fail to recognise the truth of Hunter's aphorism as exemplified in puerperal history. No poison can exist in the same subject along with another, each maintaining unchanged its specific characters. If the one does not neutralise the other, they generate between them a third, endowed with increased virulence. Happy would it be for mankind if they would but destroy each other. We find something analogous in chemical reactions of inorganic substances. Two elements uniting produce a third unlike either of those of which it is composed. This liability in the puerperal condition to rapid absorption of poisonous matter, due in large measure to sudden loss of blood, creating comparative vacuum in the vascular system, supplies an argument in favour of transfusion of blood or of saline or nutrient fluids. Of course we have at our disposal the ordinary routes of absorption by stomach or intestine; but absorption cannot,

we know, be always depended upon. It is too slow; it may be superseded by pouring what is wanted directly into the circulation. The effect of this is twofold. The immediate effect is to fill the vacuum—that is, to restore the equilibrium of pressure. This is essentially a physical result, for it is attained by the injection of fluid, as a saline solution, which can hardly be nutrient. The secondary effect is one not so generally recognised. The vascular system being renovated, the absorption of noxious stuff from the uterus and surrounding tissues is retarded, if not arrested; and thus time is gained for other antiseptic proceedings. Amongst the most valuable of these methods is the liberal supply of good food in a concentrated liquid form, admitting of easy absorption and assimilation. I am here delighted to express my indebtedness to an old friend and member of this Society, Dr. Oldham, who was one of the first to raise his voice against the old injurious rule of starving puerperal women.

Following the immediate revulsion of labour and puerperity we witness another interesting natural experiment in the course of lactation. The centre of activity of development and secretion is changed to the breasts. The action of the heart, at first lowered under the influence of hæmorrhage and the sudden revulsion from labour, soon rises again, and we witness the remarkable return of absorption and secretion. Here I am tempted again to cite a case from John Hunter. A man aged fifty had twins. The mother nursed the girl, he nursed the boy; and having begun this duty, he helped his wife in suckling eight succeeding children. The secretion held on long after he had ceased to suckle. He found that when he suckled the first child all his natural secretions were diminished, especially the sweat, to which he was much subjected before.

Another cognate reflection arises in illustration—the specially remarkable absorptive energy in children. It is a fact so familiar as almost to require an apology for intruding it; it is that when epidemic specific fevers are raging the children are attacked in larger proportion than adults. This is generally attributed to the immunity conferred upon adults by the protection conferred by previous attacks. Certainly this is true to a great extent, but it is not the whole truth; the vastly greater activity of absorption and assimilation in children is overlooked. The stimulus of developmental craving in children is so intense that the system seizes upon almost everything that comes within its reach. In childhood we also know that medicines and poisons are more active; and, on the other hand, we know that as maturity and age advance, in proportion as the developmental necessity diminishes, the need of absorption is greatly limited to the simple maintenance of the body. We may also, I apprehend, add that this argument applies not alone to our physical, but to our mental, constitution. As age creeps on the faculty of absorbing new knowledge wanes. We fall back on the past.

Let me add a few more illustrations, drawn from special clinical observations, but yielding evidence of general truths. The skin is more active in elimination or excretion than in absorption; as an excretive organ we are all familiar with the proofs given by the odours it emits. It often gives evidence of morbid internal absorption, as in the case of retained fecal and menstrual matter. To this I shall presently recur. As evidence of its absorptive capacity I may, however, mention that when a student at St. George's Hospital I saw severe vomiting follow a bath in which tartar emetic had been dissolved. With this personal observation I will pass over the subject of balneology and mineral waters. The familiar action of mercury by friction and of lead poisoning in painters may be cited, but I have seen cases that led me to believe that lead may enter by the lungs, carried perhaps by turpentine from living in rooms newly painted. I have known, as no doubt many of you also know, of cases of arsenical poisoning from inhaling the dust thrown off from arsenical wall paper; but in this case it is probable that some enters the stomach as well.

The absorptive capacity of serous membranes is well known. I will mention one example. A patient upon whom I had performed ovariectomy was poisoned by my assistant washing out the peritoneal cavity with an excessive quantity of carbolic acid solution. It seems superfluous to mention the absorptive capacity of the stomach and intestinal canal. This may be called the absorptive tract or route *par excellence*. I mention it simply for the purpose of calling attention to the tale it sometimes tells of arrested or obstructed eliminations by the natural routes. The history of obstructed evacuation or elimination is full of interest. Let any natural door of exit be closed and the imme-

diate effect is that waste stuff, the retention of which in the system is injurious, is liable to be reabsorbed under the influence of pressure turned inwards. We see continual examples of this in practice. There is the too familiar one of retention of feces, especially apt to affect girls and women. A retrograde absorption takes place, leading to a peculiar form of anæmia, sometimes to amenorrhœa. This has been worked out by Sir Andrew Clark. I have described it as a form of toxæmia, to which I gave the name "copræmia."

There are two conditions favouring absorption: (1) Comparative thirst for suction inwards; (2) obstruction at the natural outlets for evacuation. We have seen how these two conditions act in producing copræmia, urinæmia, cholæmia. Let me now give you another example replete with practical lessons. When there is mechanical obstruction to the discharge of menstrual fluid there is a retrograde absorption. This is seen in the most striking manner in cases of complete occlusion of the uterus. In these cases the serum, or more fluid elements of the blood, is absorbed back, leaving the remaining portion in a state of coagulation or liquid inspissation. This leads to a peculiar form of toxæmia. This absorption is, however, to a certain extent conservative. If it did not take place the uterus might burst, and rapid death ensue. This actually does take place in some cases of tubal ectopic gestation. When the obstruction is not complete, we meet with similar phenomena taking a chronic course and perhaps presenting intervals of recovery. This is obstructive dysmenorrhœa. I almost hesitate to trouble you with this very obvious reference; but there are men who have studied the question and deny the inference. The two forms of mechanical obstruction with which we are most familiar are the narrowing of the os externum uteri and the flexion of the cervix. When dysmenorrhœa and menstrual retention are pronounced, one or other or both of those conditions will probably be found; but some men contend that where a sound can pass, menstrual fluid can pass. Two facts dispose of this objection. First, during the turgor of menstruation the canal may become smaller by the approximation of its walls. Secondly, enlarging the opening by incision and dilatation rarely fails to give relief. Then, as to flexion, there are men who contend that fluid can flow as easily along a bent canal as a straight one, the two being of equal calibre. This is not far from true in the case of rigid metal tubes so bent that they maintain an equal calibre throughout their course; but take a living flexible tube and bend it in a strong curve, the calibre will hardly preserve uniformity throughout, and the elbow formed will certainly retard the onward flow. Again, let anyone watch the course of a stream and measure, as I have taken the trouble to do, its rate of current when the channel keeps a straight course and when it takes to meandering. In the latter case the current is not only slowed, but at every bend there is a return current or eddy which further hinders its course. Then, again, there is the clinical proof of relief following upon straightening the cervix. And this mechanical relief is soon followed by cessation of the retrograde absorption.

I said at the beginning of this lecture that almost every surface and tissue may be used as a route for the entry of nutrient and noxious matters, and I stated the correlative fact that the same routes may be used to chase noxious matter through the system. The first indication, of course, is to stop the entry of more poison; the next is to eject it; the third is, if we cannot drive it out, to neutralise or destroy it or counteract its action. Amongst the most familiar means of effecting this last indication are intravenous and subcutaneous injections; but I am anxious to mention another. The absorptive capacity of the uterus we have already seen in the case of obstructive dysmenorrhœa. I have often turned this to account by injecting solutions of iodine in septicæmic puerperal fever. The poison is thus chased through the system, and, I believe, neutralised. That iodine so injected permeates the entire organism I have often proved. It is detected by the starch test in the saliva and in the sweat. This is an example of the forces of endosmosis and of capillary attraction. Certainly the entry is not made by the veins or lymphatics alone or even chiefly. There is one undeniable proof that the iodine permeates every part of the uterus. In cases of hyperplasia, and even of fibro-myoma of the uterus, I have seen the superabundant and neoplastic tissues completely absorbed under the action of repeated injections. We may surely see in these cases telling illustrations of the good we may achieve by turning to account the absorptive energies of the system.

Here let me intrude one or two general propositions. The

true principle that should govern the physician is to interrogate all the functions, not only objectively, but also subjectively. In this way we may hope to arrive at a knowledge not only of symptoms and their true significance, but also of the physical conditions of the organs upon whose actions the symptoms depend. And thus we are directed to the true treatment not alone of symptoms—that is, the empirical medicine which has so long prevailed—but also to the direct treatment of causes which distinguishes the rational surgical medicine of the present day. Admitting, as we all must, the truly admirable and magnificent results of surgical treatment of diseases of the nervous centres achieved by Macewen and Horsley, we cannot shut our eyes to the fact that the greatest advances in our knowledge of the pathology and treatment of abdominal and pelvic diseases are due to surgical gynecology. Indeed, gynecology is nothing if not surgical. Looking at these things, we cannot help seeing that the immediate objective observation of organs whose functions are deranged leads not only to the direct treatment which takes away the disease; but that it also leads to such knowledge of the nature and properties of those organs that we may use them as media for the treatment of diseases in other organs or in the system at large. Thus the absorptive faculty of the uterus may be turned to account as a means of carrying remedial agents into the system, and so of encountering morbid germs, bacteria or other, wherever they may be. There is no agent known to me so generally powerful in this way as iodine, and we have seen that there is nothing more easy than to send iodine into every fibre, every cell of the body through the uterus. How to deal with cancer is an ever-painful problem. We may sometimes think we extirpate a cancerous growth by the knife or cautery; but we all know too well how little faith we are justified in giving to strictly local treatment. The malignant germ has seized upon internal tissues beyond the reach of the knife; but it may be chased into the remotest cell through the medium of absorption, and so kept continuously under counteracting influences.

And now I am afraid your faculty of absorption must be exhausted, and I must bring this discursive discourse to an end. I wish I could have thought out something less unworthy of association with the memory of the great physiologist whose name is the standard we bear.

## Lecture

ON

## ANATOMY AS A SCIENCE AND IN RELATION TO MEDICAL STUDY.

*Delivered at the Opening of the Medical Session in the University of Glasgow, Oct. 18th, 1892.*

By JOHN CLELAND, M.D., L.R.C.S. EDIN. &C.,  
PROFESSOR OF ANATOMY AT THE UNIVERSITY.

GENTLEMEN,—The present is a period of change in our university. Possibly this may be the last occasion on which our medical session will be arranged to open apart from the commencement of the classes in the other faculties. We trust that all changes of legislation and custom in the university will be for the better, and that if any of a contrary tendency will be imposed, at least honest and earnest work may be able to triumph over them. But there are other changes from which no institution is exempt. Students and professors alike are floated onward on the stream of time, and since last we met an unanticipated blow has fallen in the sudden removal from us of one whose happy smile and commanding figure will long be remembered, but will never again greet the eye. Of the skilful hand and kindly nature of Sir George Macleod it is not necessary that I should speak. They were well known to all his students. His sorrowing relatives and friends have the consolation that it can be said of him, as it can be proudly said of every great surgeon, that he lengthened the lives of many of his fellow men ere called himself to quit this earthly scene. But as convener of the successive committees appointed by the Senate in connexion with the University Union since the movement to originate it began, I may be permitted to call to mind the willing and important services which he whom we lament has rendered to that

institution. Nor was it at its commencement only that he gave his assistance; he continued to devote to its well-being an unremitting attention which he allowed no professional engagements to interfere with, and even so late as a few months ago he took occasion to express in writing his view of the duty devolving on the Senate to guard against the intrusion of aught which might impair its usefulness in furthering those student interests which a university ought to promote. In the Union you will remember your loved teacher as well as in your studies, and preserve that best of clubs as a centre of moral health and of earnest endeavour.

We are entering on a new era of medical tuition in this country. In accordance with recommendations made by the General Medical Council for the purpose of giving additional time for clinical study the Scottish University Commissioners have ordained that our curriculum shall henceforward extend over five years. It is a long period, but at least the universities recognise that for their students it is not too long. Even the beginners among you can already understand that to enable the humblest professional position to be occupied intelligently a foundation must be laid in a certain acquaintance with the elementary methods and principal results of the sciences on which medicine is based, and that time is required both for this purpose and to superimpose on such a foundation a rational appreciation of the present doctrines and practice of the healing art—an art which, however far it may fall short as yet in its endeavour to give to man the longest and healthiest possible life and smooth the passage to inevitable death, has made strides within the recollection of its present teachers almost incredible in variety and extent. It is, moreover, well that at the outset of your studies you should bear distinctly in mind that there is a difference between the objects to be held in view by a university bestowing degrees and a corporation or combination of corporations granting the licence to practise. It is required of the corporations to see that they license no one who is not, so far as education is concerned, fit to be trusted with the care of health and the treatment of the sick; and the universities have the same responsibility thrown on them, but with this addition: that, being the chartered guardians of the higher education of the country, it is their duty not to be content that their graduates have information up to the standard reasonably to be exacted for the safety of the public, but to demand such a course of study as shall enable those who pursue it with intelligence to examine critically the foundations of medical doctrine. It is much to know the various disturbances of health and the lesions to which the body is liable, to recognise them when met with, and to apply the remedies which the experience of others has found beneficial; but it is much more to follow out the causation of both symptoms and remedies so far as science has been able to trace them; and to do this requires a wider knowledge of the operations of nature and of the properties of substances both within the human body and in the world around. Still more special study in some particular direction will be necessary to enable you to wield with success the methods of science against the fortresses of the unknown; and not only more special study, but certain aptitudes and habits of mind, not often found in the successful practitioner, will be required, and different both from the dexterity of the born surgeon and the clinical tact of the accomplished physician. Such aptitudes and such additional study we have no right to expect from the general body of our graduates, and if we did we should not get them. It has not occurred to even the most absurd of hostile critics to demand that our medical graduates should all be men of science. Not only do I maintain that the public is entitled to expect that every graduate should have had ample opportunity of becoming acquainted with the sciences on which medicine is founded, and should have been taught to look at the details of practice in relation to these, but I would point out that the theory which has been held in the Scotch universities and raised their medical schools to note, when commissions and medical councils were unknown, is that every medical graduate should, to some extent, have systematically studied as a distinct branch of learning each of the sciences on which medicine immediately depends, and that within the walls of the university the standard of teaching in each should be maintained as high as possible. As long as this theory is held, and not one moment longer, will the faculties of medicine continue to give strength to our Scottish universities and defy the sneers of detractors. It is the merest puerility to suggest that professorial work is to be limited and pruned down to preparing students for a pass examination]

So far as the subject is concerned which is specially committed to my care, recent legislation makes little change. Anatomy will naturally be attended with chemistry in the first winter and with physiology in the second, as heretofore. The student is to be admitted to examination in the whole subject of anatomy at the end of the third winter session, the same period as that at which hitherto he has been examined in regional anatomy. But it has been considered, not incorrectly, that until then he should continue to give attention to physiological anatomy as well. The new ordinances save the student from the temptation to leave off his physiological studies immediately after attending the course of lectures on that subject, and before he has had time to master the relation of the more recondite anatomical details of function, and they leave undisturbed the opportunity of continuing the pursuit of practical anatomy in the third winter, when there is some possibility of appreciating its bearing on surgery and medicine.

The position which anatomy holds in medical education is remarkable. Assisted by chemistry and physics it forms the basis of physiology, disclosing the construction of the machine whose healthy operations physiology describes; it furnishes also the starting point of all accurate pathology, whether we regard the larger changes produced by disease or the microscopic elements out of which these are wrought; while the explicit and, to a certain extent, irksome details of its topography furnish the means of explicit diagnosis to the physician, and enable the surgeon to perform operations which without them would be impossible. These are the aspects in which anatomy is more immediately useful to medicine, and in the first of them—its connexion with physiology—it puts forward a fair claim to have an elementary knowledge of it included in general education as well. It would be a happy thing for the world if every father and every mother had some notion of physiology, and took care that their teachings and doings were in conformity with the laws of life; and, as regards higher education, it might surely be by this time apparent that some knowledge of the relation of the mind to the walls and windows of its present abode is a necessary preliminary to a correct psychology. Still all this gives no adequate idea of the scope of anatomy as a science; and seeing that the other sciences with which you are brought in contact as medical students stand in the same position, in having spheres of their own which only intersect the sphere of medicine and yet ought to be justly conceived of though not all subjugated by the medical student, I shall offer a few remarks on what anatomy really embraces. The name is misleading; it only describes a method, and that method one which in the minds of the uninitiated, even those who have been subjected to the narrow course of training supposed to constitute culture, calls up repulsive and sometimes superstitious ideas; and although everyone admits that the objects to be laid bare by that method are the details of the most complex organism that exists, this but awakens the antipathy of the lazy, while it seems never to be suspected that those details are subject to law, and result from the operation of causes, and that these also it is the business of the anatomist to discover. But when we consider how long the higher aspirations of the science have taken to germinate in the minds of those who have pursued it we learn to understand very well how the word "anatomy" came into use.

Modern anatomy is justly enough said to date from Andreas Vesalius, born in Brussels in 1514, who may be held to have originated the accurate observation and description of a large part of the body. But it must be remembered, on the one hand, that not till a later period was the whole face of the study changed by Harvey's discovery of the circulation of the blood and by the gradual growth of microscopic methods paving the way for a more rational comprehension of the objects displayed; and, on the other hand, it is not to be forgotten that the ill-satisfied longings after a knowledge of structure go back, not merely to Sylvius, the teacher of Vesalius, and to Mundinus, Paduan professor and manual-writer of the fourteenth century, but far into antiquity, to the writers whom Mundinus consulted, to Galen specially and to Aristotle, and even to Hippocrates. The crude beginnings had their origin partly in a professional desire to advance medicine, partly in the scientific ardour of speculative philosophy; but it was long before the objects laid bare by maceration and by the scalpel awoke any other thought than that of function; and thus anatomy was nothing more than such methods as the name expresses used for advancing physiology. Even Galen's work, so long authoritative, professed to be devoted to the use of the parts of the body.

(To be concluded.)

## THE THERAPEUTICS OF CHOLERA.

By SIR GEORGE JOHNSON, M. D. Lond., F.R.S.,

EMERITUS PROFESSOR OF CLINICAL MEDICINE AND CONSULTING PHYSICIAN  
TO KING'S COLLEGE HOSPITAL; PHYSICIAN EXTRAORDINARY  
TO H.M. THE QUEEN.

IN THE LANCET of Oct. 8th there is an editorial article on the "Therapeutics of Cholera," in which such frequent reference is made to me, my doctrines and my practice that I am induced to ask permission to comment upon some of the statements contained therein. The writer declares that Sir Thomas Watson in 1866 was induced to recommend the evacuant treatment of cholera "solely under the spell of his able colleague's influence," the colleague thus referred to being myself. That one of the wisest and most cautious of men, at a time when, as President of the Royal College of Physicians, he was officially at the head of the medical profession in this country, should have adopted and published a new doctrine with regard to the pathology and treatment of cholera without evidence which to his powerful and logical mind appeared conclusive is a suggestion so incredible as to require no serious refutation. The history of Sir Thomas Watson's "conversion" is simple enough. During the epidemic of cholera in 1849 I had witnessed the deleterious effects of the treatment of cholera by opium. During the next epidemic, in 1854, I ventured to give castor oil, with the result that, while in a large proportion of cases patients were rescued from extreme collapse, not one out of a large number of cases of diarrhoea so treated passed into collapse. From that time I felt assured that the theory which suggests the indiscriminate employment of opium to arrest choleraic diarrhoea must be erroneous, and that the discharges from the stomach and bowels, although they may, like the eruption of small-pox, be so copious as to kill, are yet the means by which the morbid poison is ejected from the system. Death may take place without discharges: recovery never.

Now what is the history of the theory which attributes the worst symptoms of cholera to the drain of water from the system? There is no trace of it or of the practice which it suggests in the writings of the earlier Indian practitioners. Before I published my book on "Epidemic Diarrhoea and Cholera" in 1855, I had carefully read most of the reports and books on cholera which had been published by practitioners in India before the disease appeared in Europe in 1831-32, and in not one of them did I find the slightest indication that opium was given to arrest the choleraic discharges. Opium was given to relieve the painful cramps, while at the same time purgatives, and sometimes drastic purgatives, were taken to remove the morbid secretions. The loss-of-water theory and the repressive treatment suggested by it had their origin sixty years ago when cholera first invaded Europe. This theory and practice soon gained almost universal acceptance, and one result has been that the percentage of deaths from cholera in India has been much greater than formerly. Thus Dr. Edmund Parkes, in his "Researches on the Pathology of the Asiatic or Algide Cholera," says (p. 195): "I cannot account for the astonishing success which attended the practice of several gentlemen in the earlier periods in India." He, however, thinks that the epidemics he witnessed were above the ordinary degree of severity and the mortality was proportionately great. It does not appear to have occurred to Dr. Parkes that his comparatively unfavourable results might be due to the different operation of purgatives given to remove offensive secretions and opiates given with the object of preventing their escape, the latter having been his own practice. I had observed the unfavourable results of the repressive treatment of cholera by opium and other astringents, and the comparative success of the opposite or eliminative treatment of the disease before I had formed any theory as to the nature of the disease. After a careful study of all the phenomena of cholera I arrived at the conclusion that the essential cause of choleraic collapse is obstruction of the circulation through the lungs—a result of the contraction of the pulmonary arterioles excited by the poisoned blood—and that the gastro-intestinal discharges are the means by which the poison is eliminated. This theory, which I first published in the work before mentioned in 1855, also in a smaller work entitled "Notes on Cholera" in 1866, and with much additional corroborative evidence in the chapter on Cholera in my "Medical Lectures and

Essays" in 1887, was accepted by Sir Thomas Watson and by many other competent authorities as affording a complete explanation of all the phenomena of the disease. Sir Thomas Watson says: "It is consistent with the symptoms noticed during life and with the conditions discovered after death. In truth it derives strong confirmation from the fact that it unlocks, like the right key, the whole of the pathological intricacies of the disease." Again, he says: "If the doctrines advanced by Dr. Johnson are well founded, as I firmly believe them to be, it must be wrong to dam the choleraic poison and its products within the body."

This, then, is the explanation of Sir Thomas Watson's acceptance of my theory and treatment of cholera. And surely a man in his position is to be highly commended for having the courage to publicly proclaim the fact that he had seen reason to change the opinion which he had formerly held and taught with regard to so important a subject. We know how eloquently, in his introductory lecture, he has expressed his deep sense of the grave responsibility of a public teacher. He says: "Doctrines and maxims, good or bad, flow abroad from a public teacher as from a fountain, and his faulty lessons may become the indirect source of unspeakable mischief and suffering to hundreds who have never even heard his name. These thoughts fill my mind with an almost painful sense of the obligation, imposed upon me by my present office, of closely sifting the facts and meditating carefully the precepts which I offer for your instruction and guidance." I venture to say that if all the men in high position in the profession who have privately expressed to me their entire assent to my theory of cholera and the practice deducible therefrom had, like Sir Thomas Watson, the courage to publish their opinions, there would no longer exist that conflict of opinion which at present prevails and which is a continual reproach to the profession.

It is alleged that Sir Thomas Watson had no personal experience of the evacuant treatment of cholera. In reply to this it may be observed that he had too much good sense and freedom from prejudice not to avail himself of the personal experience of others. He had read the reports of the numerous cases which I had published in detail and he refers to the still more numerous cases published by Drs. McCloy and Robertson in their very able and elaborate paper in the fiftieth volume of the "Medico-Chirurgical Transactions." In his lecture on cholera he makes repeated reference to "this most instructive communication." In their paper it is shown that 375 cases of cholera were admitted into the Liverpool parish infirmary in 1866. Of these cases ninety-one were treated with astringents and stimulants, camphor and iced water, applications of ice and hypodermic (opiate) injections, and the mortality per cent. was 71.42. Eighty-seven cases were treated with castor oil, with liberal use of food and alcohol, the mortality being 41.37 per cent. The authors express their belief that food and alcohol given during collapse were injurious and to some extent counteracted the good effect of the evacuant treatment. One hundred and ninety-seven cases were treated by castor oil alone, with a mortality of 30.45 per cent.

With regard to diarrhoea, they say, "Our experience was very extensive. Several thousand cases came under our observation in the different dispensaries connected with the West Derby Union and in the Liverpool Parish Infirmary. Among these were doubtless many which would have recovered under any mode of treatment, or by the *vis medicatrix naturæ* alone. There were many, too, of a most severe choleraic type. The treatment adopted was generally evacuant in its nature; and consisted in the administration of castor oil, calomel, rhubarb or magnesia. In every case relief was afforded 'quickly, pleasantly and safely.' It was but seldom that more than two or three doses of castor oil were required. In one of the public dispensaries (Booth) many cases of diarrhoea were treated with evacuants, and the testimony of the medical officers is in accordance with our own. 'We certainly had less trouble with the evacuant mode of treatment. Our patients seldom gave us a third visit, two doses of castor oil or rhubarb mixture being generally sufficient to cure the disease.' We never saw a diarrhoea patient treated from the commencement of his attack require subsequent removal to hospital. In a large proportion of our cases there was premonitory diarrhoea, which had been treated—often for four or five days—with astringents. Diarrhoea patients undoubtedly recover when treated with astringents, but the recovery is not consequent upon the arrest of the discharges as these are invariably restored

before the patient feels well." The authors state emphatically that "Whatever the treatment adopted the result was the same—recovery never occurred without the continuance of the intestinal discharges or their restoration if previously arrested."

In THE LANCET of Aug. 18th, 1866, p. 184, there is a report of 201 cases of diarrhoea successfully treated at the Bloomsbury Dispensary, mostly by evacuants; a pill of half a grain of calomel with three grains of rhubarb, followed in two hours by half an ounce of castor oil. If next day the purging continued a slightly astringent mixture was given, "but this was necessary in only a small number of cases." All the patients recovered, and the report states that a considerable number of them had been previously treated at other institutions unsuccessfully by astringents. "One man had been ill for a week, taking astringents the whole time; after the above treatment he went to work the next day quite well." Twenty-two of the cases were treated with coloured mint water, of whom two only returned for further treatment. I challenge the advocates of the repressive treatment of choleraic diarrhoea by opium and astringents to produce evidence in support of their theory and practice as conclusive as that which I have given in favour of elimination. The fact is that practitioners who are "under the spell" of an erroneous theory have had no experience of the evacuant treatment which they condemn on theoretical grounds alone. I have elsewhere quoted from MM. Briquet and Mignot the result of their treatment of diarrhoea by opium. Of 200 patients who came under treatment at the commencement of the attack, no fewer than 26, or 13 per cent., passed into collapse. This is a striking contrast with the many thousand cases of diarrhoea successfully treated by Drs. McCloy and Robertson. The result of the administration of opium by the mouth would be more frequently and decidedly injurious than it is were it not for the fact that the outward flux of liquid from the blood impedes the absorption of the drug, and the diarrhoea continues in spite of repeated doses of opium for a period varying from a few hours to several days. In such cases the curative efforts of nature eject the morbid poison from the blood and bowel, together with the drug, by which an attempt is made to arrest the elimination. It is now well known that Dr. Koch failed to produce cholera in guinea-pigs by introducing the poison into the stomach, unless at the same time he injected into the peritoneal cavity a dose of tincture of opium; his object being "to render it possible for the cholera bacillus to remain longer and gain a footing in the intestine." Is it not obvious that those who endeavour to arrest the choleraic discharges by opium, especially by hypodermic injections, are repeating upon the human subject the lethal experiments which Koch and others have performed upon guinea-pigs? I have reason to believe that the majority of the profession know little more of my work in connexion with cholera than that I have treated it with castor oil. They are led to suppose that I *always* give castor oil and *never* opium; the fact being that, in my detailed directions for the treatment of diarrhoea, I indicate that while there are some cases in which there is no need to give castor oil or other laxatives—the object and effect of which is, not to increase the secretion from the blood, but to quicken the expulsion of morbid materials from the bowel—on the other hand there are many cases in which, after the expulsion of the poison, opium may be usefully given to allay irritation. It is surely not too much to expect that those who publicly criticise my practice should do me and the public the justice to ascertain what that practice actually is, even if they have not the time, opportunity and inclination to make themselves acquainted with the facts and arguments upon which is based my explanation of choleraic collapse.

The influence of an erroneous theory upon the treatment of cholera affords a melancholy illustration of the truth of the following statement by Buckle: "There is no well-attested case on record of any theory having been abandoned because it produced dangerous results. As long as a theory is believed men will ascribe its evil consequences to any cause except the right one; and a theory which is once established will always be believed until there is some change of knowledge which shakes its foundation. Every practical change may, by careful analysis, be shown to depend, in the first instance, on some change of speculative opinions."<sup>1</sup> A change of speculative opinion with regard to the pathology of cholera it has been my endeavour during the last thirty-eight years to

bring about, and I am confident that the time will come when it will be generally acknowledged that my efforts have been in the right direction and that their object has been attained. Savile-row, W.

## SOME PRACTICAL DIFFICULTIES ARISING IN THE DIAGNOSIS OF PHTHISIS PULMONALIS.<sup>1</sup>

By W. S. LAZARUS-BARLOW, M.B. CAMB., M.R.C.P.

THE importance of a correct diagnosis in this the most common of the serious diseases which the profession is called upon to treat is so great that it may not be amiss to consider all some of the practical difficulties which lie in the path of medical men. I do not propose on this occasion to touch at upon the treatment of these unfortunate patients. I leave that in abler hands than mine; but the value, if there be any, in the following remarks, arises from the fact that all of the difficulties I mention have arisen to myself even in my short experience.

If a patient come to a medical man with a history of having lost two stones in weight during four or five months, if he say that he had brought up a pint of frothy blood, that he sweated copiously at night, that he had a distressing cough and expectorated much thick, yellowish mucus, and that a near relative had died of phthisis, the fears of the medical man are naturally aroused. If on examination dulness be found over one or both upper lobes of the lung, extending downwards perhaps to the third rib or lower, with tubular, cavernous or amphoric breathing associated with many moist fairly large sounds, with increased vocal fremitus and vocal resonance, increased in the case of resonance to bronchophony or pectoriloquy, his fears are realised. The patient is suffering from phthisis and probably from very actively advancing phthisis. But such is not usually the form in which the disease is seen for the first time, and particularly it is not the form in which the general practitioner sees it for the first time. It is rather in one of the other two stages, the earliest or the later stage, though doubtless in a special hospital the typical form is seen only too often. Here I should like to mention the way in which I propose to regard the stages of phthisis. I shall speak (1) of incipient, (2) of advancing, and (3) of receding phthisis. This will eliminate the difficulty which otherwise arises from the use of the stages as (1) the stage in which tubercle is laid down, (2) the stage of excavation, and (3) the vomica condition, with the attendant paradoxes that the "last stage" of phthisis may be the most favourable to the patient and the "first stage" the most dangerous. This division seems to me to be more nearly allied to the course of the disease and to afford a better explanation of the rarity of cures, as it brings so large a number of cases under the head of advancing phthisis. For the incipient stage is usually an advancing one, and while receding above the disease may be advancing below in the lung. But it is also useful as that upon which a prognosis can be most safely based, for the whole question of prognosis depends on whether, in a patient suffering from phthisis, the disease, as a whole, is advancing or is receding in activity. As the incipient stage not only comes first in order of time, but also in order of importance and of difficulty, we will discuss the difficulties then arising in the diagnosis. The second or true advancing stage, where the disease, having once taken hold of the patient, proceeds by more or less rapid strides, I do not propose to enlarge upon, as it is by far the most easy of diagnosis, cases differing but little, and that chiefly in degree, from the typical case mentioned above. In the first place, then, it is important to recognise that in the very early incipient stage a patient may not—and, indeed, is very likely not to—have any symptoms that lead to a suspicion of lung mischief. He is run down, has perhaps some dyspepsia with nausea, and probably this dyspepsia is obstinate; he is tired and languid and seems to require merely judicious diet, tonic medicine and perhaps a sea trip. Now this train of symptoms is very common and particularly so in young women. It is very common too in early summer, after the strain of winter and spring; but it is just at this season of the year that incipient phthisis is particularly likely

<sup>1</sup> History of Civilisation in England, vol. II., p. 545.

<sup>1</sup> A paper read at the North London Medical and Chirurgical Society, Jan. 14th, 1892.

to begin. I wish to enforce the necessity of not allowing such a patient to leave the consulting-room without an extremely careful examination of the apices of her lungs. Many times, no doubt, we shall find that our suspicions have not been verified; but I am confident that the earliest signs of phthisis are to be found in cases of this kind rather than in any other. Cough, expectoration, hurried breathing, perspiration and hæmoptysis are conspicuous by their absence; but a careful examination may reveal a little dulness in the supra-scapular fossa, a slight roughness, harshness or waviness of breathing, particularly in expiration, perhaps a few clicks, not cleared up by deep inspiration or cough, and we shall congratulate ourselves on having avoided that greatest of errors—the overlooking of the prime cause in the prominence of extraneous symptoms. I need not say that the importance of careful examination in such cases is essential to the advantageous employment of climatic treatment, and in no stage of phthisis is climatic treatment more advantageous. Perhaps we may not have time to examine for bacilli, but if we do we may be rewarded for our pains. I have notes of one case that occurred when I was house physician at the Brompton Hospital which illustrates this point very forcibly. The patient, a young girl of nineteen, had absolutely nothing the matter with her but some persistent dyspepsia, and to get sputum for examination it was necessary to make her cough. There was even then expectorated a little watery mucus alone, nothing similar to the ordinary phthisical sputum; but bacilli were present in large numbers, and within the three months of her stay signs appeared in the left apex. The fact that bacilli were discovered within the first week after her admission negatives the possibility of her having contracted the disease within the hospital.

We may now advance a little further. We have in early spring, or perhaps even in summer, a patient who has persistent slight cough, with slight glairy expectoration, which has lasted through the winter and has got a little worse; perhaps some lassitude and maybe a phthisical family history. Is the patient the subject of incipient phthisis? To my mind this all-important question is most difficult to solve. Many persons show a liability to cold and their catarrhs go on to a bronchial catarrh. It is particularly in the upper lobes that this bronchial catarrh is likely to persist for some time, and it is especially under the conditions of a prolonged bronchial catarrh that tubercle is likely to be deposited. How are we to determine whether the patient is suffering from a mere bronchial catarrh or from early phthisis? Frankly I confess that I cannot do so with certainty; nothing but time will show with absolute certainty. But there are some indications that may give one or other of these diagnoses more probability. In such a case it is of especial importance that the bodily temperature be taken regularly, and not only night and morning, when it will very likely prove to be normal, but especially in the middle of the afternoon. If the temperature rises in the afternoon from 2 to 5, but is not elevated above the normal night temperature in the evening, or only slightly, I believe the probabilities are greatly in favour of the tuberculous condition. Next we should notice the effect of causing the patient to cough while we are auscultating. The long inspiration following the expiratory effort of coughing will very possibly clear up to a large extent the sticky râles, or the clicks, which in such a patient are heard during ordinary breathing. If after repeated cough with subsequent deep inspiration, and after several auscultations, these clicks remain, the probability of phthisis is increased. Then there is help in the question as to whether the conditions of the two lungs are similar. If there is no dulness, if the moist sounds may be heard equally low on both sides, if the degree to which they are heard varies from one day to another, and if an occasional click may be heard at the bases, then the probability is in favour of bronchial catarrh. If the sounds are not heard equally low, and particularly if the left apex be more involved, there is increased fear of the condition being phthisis. The question of time will usually clear up the difficulties in these cases, and it is important not to let a patient who has had this condition in early summer enter upon the next winter without carefully arriving at a definite conclusion as to the actual condition of the chest. If, when the patient is examined in autumn, nothing is found, the mystery has solved itself; if the same condition remains or has advanced the probability is vastly increased that he is suffering from slowly advancing early phthisis, and by this time other symptoms will probably have supervened, converting the diagnosis from a comparatively

doubtful to a comparatively certain one. Nevertheless, I do not ignore the fact that a bronchial catarrh may creep on. At any rate, if we thus exercise caution and take pains over the diagnosis we shall have nothing to reproach ourselves with in case the more serious condition ultimately manifests itself. We shall in the meantime have given the patient the best chance of escaping that tuberculous disease, and shall have put him under those conditions which militate most against its rapid advance. Such considerations are amply sufficient to compensate us for the extra trouble we have taken in arriving at a diagnosis.

We now come to a very different class of case, one in which the diagnosis is no less difficult, but which cannot alter our treatment to any considerable extent, though the prognosis may be materially modified. An example of this class is very vividly before my mind, as it was one of the cases given me in my examination by the Censors' Board of the College of Physicians. I will briefly run over the chief points. A man in the prime of life was admitted to hospital with acute pneumonia; the case never had a definite crisis, but went on for about two months, at the end of which his condition was as follows: Dulness, with all the signs of fluid in the lower axilla and at the base on the right side, with a few crepitations throughout the lung; temperature irregularly raised, pulse rapid and copious perspirations. It was evident that pleural effusion had been added to the pneumonia, but the question was whether tuberculous mischief was not, after all, underlying the whole. Now the effusion at the right base raised the tone on percussion of the upper lobe, though it was by no means of the Skoda type, and thus abolished a means of comparison with the left upper lobe. The onset of the pleurisy was definite, with rigor and pain. But the onset of a tuberculous pleurisy is most commonly insidious and pain is not a marked symptom. The condition of the patient was quite explicable on either of three hypotheses: (1) unresolved pneumonia, (2) empyema, and (3) phthisis being laid down on an unresolved pneumonia. There was no tuberculous family history, and yet the man looked of a tuberculous diathesis and his finger-ends were clubbed. He had had no previous illness, no history whatever of cough or wasting; he expectorated much frothy mucus. And yet, in spite of all, there was in my own mind, from the first no doubt—and I may add that the Censor examining also fully concurred in my view—that the case was tuberculous at bottom. Upon what could that diagnosis be upheld in the face of so many contradictory signs? In the first place, there was some harsh breathing at the left apex, and this side was duller on percussion than the right, though I admit the abnormal condition of the right lung gave no satisfactory standard of comparison. Then, next, the finger-ends were clubbed. I do not know how long it takes for obstruction to the pulmonary blood-supply to exist before clubbing is present, but it appeared to me that two months was long enough. Thirdly, the peculiar hopefulness of phthisical patients was present here, and this, with the transparent skin and pearly sclerotic, together with the fact that now, two months after admission, his lung condition was not cleared up, but actually more obscure than ever, led me to the conclusion that phthisis was the disease which would later on, by rapid strides, infiltrate and perhaps excavate the lungs on both sides, but particularly the right; in short, that tubercles were being laid down throughout the area of an unresolved pneumonia. Here was a case where discovery of the bacillus would have been of inestimable advantage to the diagnosis; but I was assured that examinations of the sputum had been repeatedly made without success.

Closely allied to the above case are those somewhat rare cases of apical pneumonia. They occur more frequently in children, are accompanied with much more pronounced symptoms, and are long in resolving. One must not forget that though tubercle going on to excavation is far less common amongst young children than amongst adolescents and adults, yet that it is not infrequently met with. If in a case of apical pneumonia in a strumous child we can get but a very poor history of onset, I do not myself see, unless delirium be marked, how we can differentiate the two diseases. Dulness, tubular breathing, bronchophony, and even pectoriloquy, are present in both, and the onset of phthisis in children is often so rapid that the mode of onset in any particular case may help us but little. I think here in many cases, though we must recognise the condition as extremely severe, we are unable to give a definite diagnosis. The case is different from broncho-pneumonia in children; moist sounds and dulness are very widespread, but they are

not as a rule confined to the apex, being heard in patches all over the chest on both sides, and particularly below the angle of the scapula. In children cases of broncho-pneumonia ought not usually to cause any difficulty. But it is different in adults. When broncho-pneumonia is present it may lead to a condition very similar to that occurring in basal phthisis. True phthisical cavities also rarely occur at the bases of the lung, and may be confounded with bronchiectatic cavities. A diagnosis may usually be effected by considering other symptoms—such as the deteriorated condition of health dependent upon some long-standing acute illness which has exhausted the vital forces, leading to broncho-pneumonia and the peculiar mode of expectoration with the characteristic odour of the sputum in bronchiectasis. In a short time influenza, leaving broncho-pneumonia, may further increase our difficulties in diagnosis. With regard to morbid growths in the lungs I can speak with less confidence, as I have met with but few, and those such in which the diagnosis was not difficult, and in any case not to be confounded with phthisis. Primary growths in the lung are very rare, and generally the organ is invaded from the mediastinum, and presents many points of contrast to what occurs in phthisis. I can nevertheless easily imagine that a localised, easily softening growth might be very difficult of recognition.

Having now briefly pointed out the main conditions found in the lungs which may considerably affect our diagnosis of phthisis I should like to refer to a few of the more important symptoms which, though often of extreme diagnostic importance in phthisis, are nevertheless not pathognomonic. Firstly I will deal with hæmoptysis. Dr. Burney Yeo lately said that often hæmoptysis was the most favourable condition towards the cure of phthisis, as it made the patient take adequate precautions. That is no doubt true, but we must primarily be certain that the hæmoptysis is of tuberculous origin. I need not speak of the importance of deciding whether the case be one of hæmoptysis or hæmatemesis. I assume that it is undoubted hæmoptysis. Now in middle-aged and elderly persons hæmoptysis is not so simple a matter as it seems. Most probably, I grant, it comes from a cavity with vessels running in its walls that, being unsupported on one side, have become aneurysmal. But there are two other questions to be disposed of: (1) Does the hæmoptysis depend upon the same causes as lead to cerebral hæmorrhage and epistaxis in the subjects of chronic renal disease? and (2) Does the hæmoptysis arise, as Sir Andrew Clark has shown it sometimes does, in a person of arthritic tendency and quite apart from either renal changes or phthisis? Now renal hæmoptysis, if I may so call it, may be easily diagnosed by the state of tension of the pulse, and above all by deciding by gentle percussion the extent of the cardiac area. The size of the heart will settle the question. If dulness extend up to the upper border of the third rib and beyond the middle of the sternum I believe phthisis may practically be put out of the question; for the heart in phthisical patients, in the immense majority of cases, is below the normal weight and size, while in chronic renal disease, as is well known, it is generally hypertrophied. So far I have only seen one case of Sir Andrew Clark's arthritic hæmoptysis, and in that the amount of blood expectorated was considerable and lasted over several days; the patient was about fifty years of age; there was no renal disease and absolutely no ground for assuming phthisis after many most careful examinations. On the other hand, the patient exactly answered to the type of case Sir Andrew Clark has described. I confess though that at first I regarded the blood as coming from an undiscovered phthisical cavity. Secondly, wasting may mislead us. There are few diseases in which wasting is so great or so rapid as phthisis, and yet I remember one case I saw early in 1890 in which most marked wasting took place as the result of mere inanition in a patient suffering from hysteria; she was fifteen years of age and was reported to have maintained life on half a pound of grapes and some raspberry jam for a period of three months. That fact, aided by the knowledge that she was regarded as a marvel in the small village where she lived, caused me to doubt the diagnosis of phthisis publicly given out by the medical man in attendance. I examined her most carefully, found no tuberculous mischief, but had my provisional diagnosis of hysteria confirmed in a number of ways that need not now be recapitulated. Removal from the surroundings, strict moral treatment combined with forced feeding and massage, produced in a month so considerable a change in the patient's physical condition that I had great trouble to protect her from the unkind remarks of her neighbours, who had previously been so

loud in their expressions of compassion. If she had had a slight "bronchial catarrh" at the same time I should not have felt so certain of my diagnosis. Thirdly, as regards cough and expectoration. It is necessary to remember that cough need by no means be caused by a lung condition. Irritability of the fauces, a pendulous uvula, any irritation about the larynx or in the ear may cause it, and when combined with some expectoration, as it usually is, and of lengthened duration, any of these causes may lead to an unfounded suspicion that phthisis is incipient. The granular condition of the pharynx common in cigarette smokers is a typical example of this. The cough and expectoration will last throughout a summer and give rise to alarm. Whenever, therefore, cough and expectoration are present and chest symptoms are absent or of very small extent, we must not assume the existence of phthisis until we have decided that the throat cannot possibly or sufficiently account for them. There must be a cause for them, I grant, but with patience it will be found, and possibly not in the lungs; while it is as satisfactory to find them dependent upon a remediable throat condition, for example, as it is unsatisfactory not to refer them to a lung condition upon which, notwithstanding the absence of chest signs, they may nevertheless depend. With regard to the expectoration, some slight reference is necessary. The sputum of phthisis, though typically nummulated, is not always so. Many cases, and particularly those in an early stage, produce only "bronchitic" sputum, and yet bacilli may be found in quantities. This was the character of the sputum in the first two cases I have mentioned above. Next you will find some cases of bronchiectasis and of chronic bronchitis in which the sputum is typically nummulated. With these cases one word of caution is necessary. Cases of chronic bronchitis are not always uncomplicated and often with them coexists an old fibroid phthisis; it is very necessary to inquire for a history of phthisis in early years before one concludes with certainty that the nummulated sputum in an apparently simple case of chronic bronchitis does not come from an old much-contracted cavity. Fourthly, hectic temperatures and sweating are not peculiar to phthisis; I remember at least one case of empyema where such a mistake was made. Remember also that apical emphysema may surround and mask an old nodule of tubercle. The importance of searching for underlying quiescent phthisis in chronic bronchitis and emphysema is great on account of the tendency such lesions have to smoulder on and some time or other burst into active growth. Lastly, I should like to mention two small points of practical value in the diagnosis of a cavity, and the first is that in examining a patient for pectoriloquy or whispering pectoriloquy it is advisable to make him read from a book rather than say the familiar "one, two, three," or "ninety-nine." If, in taking care that the unoccupied ear does not receive the sounds we are able by means of the auscultating ear to understand the words whispered, the diagnosis of a cavity may be absolute, but when the words are familiar we are apt to think we hear more than we actually do hear. The second point is that the character of the cough is important; an impulsive cough, seeming to rush up the stethoscope, may be heard when pectoriloquy is not obtainable, and, I believe, is of extreme value in diagnosis. Such a condition I have often noticed in cases of receding or fibrotic phthisis in which a cavity is becoming contracted. As may be easily understood, it is a particularly valuable sign from a prognostic as well as a diagnostic point of view.

Bryanston-street, W.

## DYSPEPTIC HEADACHE: A HISTORICAL SKETCH.

By HARRY CAMPBELL, M.D. LOND. &c.

THE intimate sympathy between the head and the stomach was well known to the ancients. Thus Galen alludes to the vomiting which may follow upon fracture of the skull and to the headache which may result from gastric disturbance.<sup>1</sup> Cœlius Aurelianus and Alex. Trallianus also, among other writers of antiquity, insist on the consensus existing between these two parts of the body,<sup>2</sup> and it has been con-

<sup>1</sup> Kuhn's edit., vol. viii., pp. 178, 179.

<sup>2</sup> Labarraque: *Essai de la Céphalalgie et la Migraine*, p. 24. Paris, 1837.

stantly commented upon from their time to our own.<sup>3</sup> But while thus recognising it, and even observing that a similar sympathy or consensus obtains between all parts of the human frame, these old writers had only dim notions as to how it was set up. Nevertheless, in their gropings after its cause they came very near to the true explanation, so far as head and stomach are concerned. Galen, for example, definitely attributed the headache resulting from gastric disorders (1) to the numberless nerves which, passing from the head to the stomach,<sup>4</sup> allow any gastric disturbance to be readily felt in the head, notably disturbances arising from the presence of yellow bile<sup>5</sup>; (2) to indigestion causing certain irritating humours and vapours to pass from the stomach to the head—"for the head does not only ache when itself diseased, but on account of the stomach, which transmits the vapours of morbid humours."<sup>6</sup>

Coming down to a much later date, we find the subject summed up by Montalto in the following passage: "Magnus enim cerebro consensus ex duplici pendet causa; prima est positus et rectitudo, cuius causa ascendentes vapores prompto suscepat; altera nervorum est communitas."<sup>7</sup>

The views of Galen are remarkable, for they are fundamentally the same as those held at the present time. The modern theory is that morbid states of the alimentary tract affect the head in consequence (1) of nerve currents streaming upwards, (2) of the accumulation in the blood of poisons resulting from indigestion. These substances the ancients regarded in the light of morbid humours and their vapours, while we call them ptomaines, leucomaines, and nitrogenous excreta. They recognised as clearly as we do the existence of something which, travelling about the body, exercises an injurious influence upon it. Nor does the harmony between the views of the ancients and those held to-day end here; they, too, attributed a greater influence in the production of the head troubles resulting from gastric disturbance to the "morbid humours" than to the nervous system. It was for the men of a later age to lead us awhile into the error of regarding the nervous factor as the more effective of the two, and perhaps it is not to be wondered at that, just when the functions of the nervous system were beginning to be understood as they had never been before, its importance in this respect should have been unduly rated for a time. Indeed it was but natural that the brilliant work done in neurology by Willis, Whytt, Marshall Hall, and Brown-Séguard should, by awakening a proper sense of the importance of peripheral irritation in causing central nerve disturbance, somewhat blind the eyes of pathologists to the other agencies aiding to produce the headache and other cephalic effects of indigestion. Now, however, that we are no longer dazzled by the new light, we are beginning to see again what the ancients dimly saw long ago—that it is blood poisoning that plays the most important part in the causation of the phenomena under consideration. Nevertheless, even now there are some who attribute a very marked influence to irritation of the visceral nervous system. Thus Mercier holds that the abdominal viscera influence the head by their power of modifying the nerve tension in the visceral moiety of the nervous system.<sup>8</sup>

Seeing then that so many ill-effects of indigestion are undoubtedly due to the action of poisons—call them acrid humours, vapours, leucomaines, urates, or what we will—I shall briefly pass in review some of the theories which have been current on the subject so far as they relate to headache. Since the time of Galen yellow bile, one of the cardinal humours, has been regarded as a cause of headache, and it still is by the laity and by not a few physicians. Trallianus,<sup>9</sup> who lived some years later than Galen, and Haly Abbas, who,

<sup>3</sup> See such passages as "Consensus ventriculi cum capite et capitis cum ventriculo" (Hoffmann); "Magnum inter ventriculum et capitis interiores membranas ipsumque cerebrum esse consensum, multis experimentis novimus" (De Dolore Capitis, J. F. Stuckens, Brux. 1787). Similar remarks are frequent.

<sup>4</sup> "For the brain transmits to the stomach, and the stomach to the head, its own affections, by reason of the abundance of nerves passing from the brain to the mouth of the stomach." Kuhn's edit., vol. viii., p. 179. Galen was familiar with the vagus and its distribution. The two vagi constitute his sixth pair of nerves. He speaks of the sixth nerve giving branches to the larynx, the lungs, the heart and the stomach, and he names the branches which enter the larynx from below "the recurrent laryngeal." He was also acquainted with the motor and sensory nerves. See vol. iv., pp. 371, 528, vol. iii., p. 384.

<sup>5</sup> Galen says in effect: "Headache may be caused by yellow bile either in the stomach or the head." Opus cit., vol. xvi., p. 49.

<sup>6</sup> Opus cit., vol. vi., p. 807.

<sup>7</sup> Archæopathologia, p. 137. 1614.

<sup>8</sup> Sanity and Insanity.

<sup>9</sup> See Livinge: On Megrin &c., p. 235. London, 1873.

in common with most Arabian physicians, borrowed largely from Galen, both follow him in looking on bile as one of the commonest causes of sympathetic headache, and allude, like him, to the relief to the head obtained by vomiting.<sup>10</sup> Very much the same views are to be found in the writings of the Middle Ages and later. Thus Charles Lepois attributes megrim to bilious vapour forcibly travelling upwards and distending the cerebral vessels,<sup>11</sup> and in the Sepulchretum of Bonetus<sup>12</sup> we read of a case of headache: "Cujus nulla alia in corpore causa deprehensa quam bilis cystim fellæam distendens." It is argued that the gall-bladder being distended with bile and having no room for more, this secretion "crurori confusa ad cerebrum delata est." Fernelius speaks of headache arising from bilious vapour, and, indeed, cases of this kind might be quoted from the older writers *ad infinitum*. No doubt these views took their origin in the phenomena of megrim, which is commonly known as "bilious headache." That a headache attended by bilious vomiting, and in many cases distinctly relieved by the act of vomiting, should be thought to have a biliary origin was but natural. When, however, megrim came to be regarded as a nerve storm and the gastric symptoms as secondary—the results of a primary central discharge—the influence of the bile in provoking the attack was in large measure disregarded. No writer has done more towards consolidating and furthering our knowledge of megrim than Livinge, and he, in his anxiety to emphasise the secondary character of the gastric phenomena accompanying the paroxysm, seems unwilling to admit that errors in biliary secretion may be a possible factor in causing the attack, although he acknowledges that previous dyspeptic troubles may contribute to it. Alluding to the popular opinion, which regards bile as a cause of headache, he writes: "As in so many other instances, what was once the teaching of the philosopher is preserved to us only in a fragmentary form in popular language and traditions."<sup>13</sup> There are still, however, physicians who hold that the bile may play some part in causing megrim. Lauder Brunton, for example, thinks that the popular belief in regard to bilious headache is not altogether erroneous. He looks on bile as an accessory, not a primary, factor in its causation, the poisonous element consisting of an alkaloid; and he points out how in these attacks the mere effort of retching, without bringing anything up, sometimes does good, probably by its mechanical effect on the liver.<sup>14</sup> But even granting that disorders of the biliary secretion take little or no part in causing megrim, few will deny their power to set up headache of some kind; and we have to take into account not only excessive, but also deficient, secretion of bile. Deficient secretion implies a sluggish liver, and a sluggish liver is obviously a cause of headache, leading as it does to blood poisoning; for not only is there imperfect transformation of the poisonous substances brought to it, but the insufficient supply of bile in the intestines resulting from its inactivity gives rise to the undue generation of poisons there. How profound are the nervous disturbances (headache included) which may result from errors in the hepatic function is well shown in acute yellow atrophy. Murchison, as we all know, attributed lithæmia, of which headache is a prominent symptom to the liver, and more recently Haig has pointed out the causal relation between uric acid (the formation of which is perhaps closely associated with the hepatic function) and megrim. If, then, we regard the biliary secretion as typifying the hepatic functions in general, we must admit a considerable measure of truth in the old views which represented bile as a cause of headache.

Another cause, according to the ancients, was imperfectly digested food. Thus Haly Abbas writes that defective sleep causes headache by occasioning "a corruption of the food in the stomach," and he adds, "protracted sleep in like manner fills the brain with vapours"<sup>15</sup>; while, like Galen, he alludes to the plentiful supply of nerves passing from the stomach to the head, he does not attempt to explain how headache can be induced by their instrumentality, and there can be little doubt that he followed the old Roman physician in regarding the vapours which were supposed to pass from the alimentary canal to the head as exercising the preponderating influence. That this view prevailed even down to the time of Willis is evident from the following passage: "Headaches which

<sup>10</sup> See Paulus Ægineta; Trans. from the Greek, with a commentary, by Francis Adams, 1844, London, vol. i., p. 864 et seq.

<sup>11</sup> Selectiorem Obser., 1, My. Opus novitate doctrinæ &c., 1618.

<sup>12</sup> Quoted by Wepfer: Observations &c. de Affect. Capitis. Scaphusii, 1727.

<sup>14</sup> Disorders of Digestion, p. 295. London, 1830.

<sup>15</sup> Paulus Ægineta, opus cit., vol. i., p. 364.

seem to begin in the viscera, and commonly called sympathetic, are wont to be ascribed to vapours—viz., by supposing a mine of noxious humour to lie hid in some inward, from which being moved, whilst the effluvia ascend to the head and thence sharply pierce thorow and pull the nerve fibres, pains are excited."<sup>16</sup> Here no mention is made of any theory of a nervous connexion between stomach and head; and it can scarcely be doubted that so learned a physician as Willis would have referred to it if such had been generally held in his time. Galen, in fact, did little more than state as an anatomical truth that the head and the stomach were connected by nerves; he did not elaborate the physiological aspect of this connexion, and hence his observations seem to have had little influence on subsequent thought, so little indeed that Willis may almost be said to have rediscovered the connexion. Far from contenting himself with a bare anatomical statement, this physician sought to explain how the head is influenced through the gastric nerves. As a result of an irritating humour in the stomach, "a convulsion or corrugation, very troublesome, is impressed on the fibres and extremities of the nerves there inserted, which immediately being continued into the head by the passage of the same nerves of the eighth pair (vagus) and of the intercostal<sup>17</sup> (sympathetic) is communicated to the membranes and the nervous fibres predisposed to painful wrinklings ..... [and thus the headache is produced]. By reason of the same reciprocal communication between the stomach and the head a nauseousness and vomiting follow upon the headache—viz., the membranes being stirred up into painful wrinkling ..... and transferring the evil by the passage of the nerves to the ventricle [stomach], guiltless itself," &c.<sup>18</sup>

More than a century later, however, we find from the writings of Whytt, another English physician, that these views had gained little hold on the medical mind. Whytt, it may be remembered, explained the sympathy between the various parts of the body as due to the union of nerve fibres in the centres of the brain and cord, and not, as Willis had conceived, by the anastomosis of the nerves; "for," he argued, "there is a remarkable sympathy between many parts whose nerves have not the smallest communication with one another."<sup>19</sup> The fallacy which Whytt points out is constantly maintained even to-day. The renowned Hilton was misled by it. But this by the way.

That the observations of Galen, or of even those of so late a writer as Willis, on the nervous connexion between the stomach and the head made little impression on Whytt is shown by the following passage: "Hippocrates was not wholly ignorant of a general sympathy between the parts of the body, and Galen treats particularly of those diseases which arise from sympathy or consent, but he was so far from having any notion that sympathetic affections were owing to the nerves that he ascribes those headaches which do not proceed from any fault in the head to vapours ascending from the stomach or uterus. Succeeding writers, even as far down as Fernelius and Sennertus, seem to do little more than copy what Galen has said on this subject."<sup>20</sup> Living<sup>21</sup> is not slow to point out that Whytt fails here to do full justice to Galen, nor, indeed, is he fair to Sennertus, who in his chapter on headache insists most explicitly on the great sympathy established between the head and the stomach by virtue of the nerves, though he attaches the chief importance to the influence of humours and vapours in causing the head to suffer secondarily to the stomach. These, he contends, are especially apt to come from the stomach, "from which they ascend to the head by means of the œsophagus. Humours and vapours may also come by the veins and arteries and other channels, from the liver, the spleen, the uterus &c., for the head, like the roof of a smoky house, receives whatever fumes rise from below, and is necessarily influenced by all parts of the body, owing to the intercommunication of vessels which ramify through it."<sup>22</sup>

Indeed, there can be little doubt that not only Sennertus, but writers down to the end of the last century, explained those cephalic disturbances which follow upon gastric trouble chiefly on the lines of the humoral pathology, nervous influence (in spite of the brilliant work of Willis) receiving but little consideration. With an increased knowledge of nervous action we have seen, however, that these came for a time to be considered the chief means by which the stomach affects the head, and at the present day we are practically reverting, if not to the actual letter, at all events to the spirit of the older pathology in that we are again giving more weight to the influence of poisons in the blood. We are, in fact, beginning to see that just as Willis; when he wrote of a nerve being "convulsed and corrugated," was expressing in his own way a great truth, so, underlying the quaint conception of morbid humours and vapours, lay a grand fundamental verity—that cephalic troubles which are set up by gastric disturbance are chiefly caused by blood poisoning.

Guilford-street, W.C.

## Clinical Notes :

### MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL.

#### ACUTE THYROIDITIS.

By J. C. M. GIVEN, M.B. LOND.,

LATE ASSISTANT MEDICAL OFFICER, DERBY BOROUGH ASYLUM.

THE rarity of acute thyroiditis, together with the gravity of the symptoms and its sudden onset, makes, I think, the following case worth recording.

M. B.—, a nurse aged twenty-three, was taken ill suddenly on April 5th, 1892, with general malaise and pain in the neck. That evening her neck began to swell, her temperature rose to 105.3°, and she complained of difficulty in swallowing and breathing. Next morning, on examination of the thyroid region, there was found to be a large tense swelling extending laterally to the sterno-mastoids downwards to within an inch of the sternum; above it was limited by the hyoid bone, which could just be felt, but on each side of that structure it extended upwards to the angle of the jaw and the mastoid process. On palpation it was exceedingly tense, non-fluctuating and very tender to the touch, and did not move on deglutition. The enlargement was of such a size that the patient could scarcely separate her teeth, and that the normal depressions over the anterior triangles and the prominence of the thyroid cartilage were completely obliterated. Deglutition was extremely difficult and there was occasional inspiratory stridor. The fauces were slightly congested, but otherwise normal. The patient was evidently very weak. Pulse 140, soft and small. On April 7th the general condition was rather better; temperature 102°. The swelling was now fairly localised to the thyroid gland, and moved slightly on swallowing. The difficulty of deglutition was much less and the inspiratory stridor was absent. On April 8th the enlargement had slightly decreased, but some subcutaneous œdema, most marked on the right side, had appeared; there was no redness of the skin and no definite fluctuation, and as the urgent symptoms were abating, the surgical interference, which at first was thought would be necessary, was postponed. Leeches were applied, and the hot fomentations which had been used from the commencement were abandoned. After this the patient steadily improved; on April 14th the swelling was almost confined to the right lobe of the thyroid, which was still tense and tender and semi-fluctuating. The measurement round the most prominent portion of the neck was fifteen inches and a quarter. The temperature still went up to 101° at night. On April 21st the swelling had sensibly decreased, neck measurement fourteen inches, and the patient had been getting up for a little time each day, her temperature being normal. On May 24th she came back, having been away for a change, and stated that she felt quite well. The measurement of the neck was thirteen inches, and she now wears the same collars that she did before the attack.

The treatment adopted was expectant. The two great difficulties were, first, to diagnose the trouble in the first forty-eight hours from a diffuse cervical cellulitis; and, secondly, to determine in the later stage whether pus was forming in the

<sup>16</sup> De Anima Brutorum, Sect. on Headache. Eng. Trans.

<sup>17</sup> Up to this point Willis's conception may be regarded as almost exactly representing our views to-day. The conception of a convulsion or corrugation being continued along a nerve corresponds pretty accurately to the modern notion of a nerve current. Indeed, in some respects the phraseology which Willis employs is preferable to our own. The term "current" suggests the flowing of some material thing along the nerve, and is, I suppose, the relic of the old notion of a nervous fluid. Willis was much before his time as to the mode in which a nerve shock is propagated.

<sup>18</sup> I find the above passage from the English translation of Willis's works quoted almost word for word in the Sepulchretum, vol. i., p. 4.

<sup>19</sup> Observations, p. 42. Edinburgh, 1765.

<sup>20</sup> Ibid., p. 87.

<sup>21</sup> Op. cit., p. 255.

<sup>22</sup> Sennert Opera, tom. ii., p. 630. Lugd., 1660.

thyroid. Fortunately this did not occur. She was freely fed with nourishing food and was ordered ten minims of tincture of perchloride of iron every three hours. It appears that before the attack she had always a slight fullness of the front of the neck, but it was so slight that it had never been noticed by her friends. The exciting cause is unknown, there having been no definite exposure to cold; but with regard to the predisposing cause it is interesting to note that the patient had had acute rheumatism, which disease was said to be in close relationship to such cases as those related by Dr. Angel Money at the Clinical Society in 1887, when the only other similar case I can find reported was read by Dr. Barlow.

Liverpool.

#### ARSENICAL POISONING: DEPOSIT OF SULPHIDE OF ARSENIC ON THE ENDOCARDIUM.

BY SURGEON-MAJOR R. D. MURRAY,  
CIVIL SURGEON OF HOWRAH, BENGAL.

THE following case is extremely interesting both from a police and a medico-legal point of view.

On Aug. 7th last at 9.30 A.M. I received intimation that the police had brought a box to the Howrah General Hospital dead-house. They stated that the box had been booked as a consignment from Patna city to Howrah. On arrival at Howrah the odour and fluid leaking from the bottom of the box attracted the suspicion of the authorities, and it was determined to break it open and find out the nature of the contents. It was then discovered to contain a decomposing human corpse packed in paper shavings. A post-mortem examination was made at 11 A.M. on Aug. 7th. The body was that of an adult Mahomedan female, perfectly naked, without ornaments and laid on its back with the limbs doubled up on the trunk. Decomposition was fairly advanced, but there was comparatively little odour. The features were bloated beyond recognition; the left eye was protruded, mouth open, lips swollen and everted, left lateral incisor tooth of lower jaw absent, body purple and green in places, cuticle peeling, prolapsus of vagina and rectum. No distinct external signs of violence could be detected beyond a suspicion of injuries inflicted over the front and upper part of the chest, where there was an appearance of general diffuse ecchymosis and congestion. These may have been post-mortem changes. The scalp was swollen and congested and indented from pressure against the side of the box. The membranes were of a livid purple colour, the brain decomposed and diffuent. On opening the body I was struck by the fresh and well preserved appearance of the viscera and the absence of the usual foul putrid smell. This was especially marked in the case of the abdomen. The air passages and pleura were deeply congested. The lungs were semi-collapsed, much congested, and floated very heavily in water. The pericardium was normal. The heart was soft, from post-mortem changes, and empty; valves healthy. The endocardium of the left ventricle presented a peculiar bright-yellow stain or deposit over one-third of its area, as if iodoform had been powdered on it. The peritoneum was generally congested and of a rosy hue, especially over and in the region of the stomach. The mucous membrane of the stomach was intensely congested and ecchymosed in patches; it contained about eight ounces of reddish-brown fluid. The small and large intestines were congested throughout and contained a bright-yellow odourless fluid. There were no faeces. The liver and spleen appeared healthy; the kidneys were deeply congested; the bladder was empty, and the rectum, uterus and vagina were prolapsed. The stomach and its contents, the heart, portions of the intestines and their contents and also portions of the solid viscera were preserved and sealed for chemical analysis. I suspected that death was the result of poisoning by arsenic, and subsequently the chemical examiner's report fully confirmed my opinion. The important points were: (1) The unusual degree of preservation of the interior of the body as contrasted with the external decomposition owing to the antiseptic action of the arsenic; (2) the remarkable action of foul odour on opening the abdomen and alimentary tract (from the same cause); (3) the extreme congestion of the peritoneum, stomach and entire intestinal canal; (4) the bright-yellow odourless fluid contained in the intestines and the small mineral particles floating in it at once suggested yellow arsenic in suspension; (5) the deposit of yellow sulphide of arsenic on the endocar-

dium as reported by Professor Warden. So far as I know this is the first time that metallic arsenic has ever been found as a deposit or precipitate in the heart in cases of arsenic poisoning. In this case the dose of arsenic administered must have been very large, and the poison was probably mixed with or given instead of turmeric, which is so largely used by the natives in their diet. Being tasteless its detection during the meal would be easily frustrated. Arsenious oxide, however, may have been the form administered, as it can be converted into sulphide in the body. The appearances of the chest-walls, lungs and air passages were suggestive of violence by compression of the chest and strangulation, but on account of decomposition a definite opinion was impossible on this point. Most probably the woman's cries were stifled so as to prevent an alarm being raised, especially as the dose of poison administered must have been large and the pain and gastric disturbance severe and urgent. The murderer has since been captured and has confessed his crime. The police found a packet of yellow arsenic in his house.

Howrah, Bengal.

#### FRACTURE OF UPPER END OF THE ULNA, WITH DISLOCATION OF THE HEAD OF THE RADIUS.

BY HENRY WILLIAMSON, M.R.C.S., L.R.C.P. LOND.,  
LATE HOUSE SURGEON, ANCOATS HOSPITAL, MANCHESTER.

G. R. P.—was brought to the hospital on June 4th with an injury to the forearm caused by direct violence. On examination I found a fracture of the upper end of the ulna nearly three inches and a half from the top of the olecranon. Not being able to rectify the displacement of the upper ulna fragment I made a more careful examination of the limb and found that the head of the radius was dislocated forwards. On reducing the dislocation it was found that we had partly rectified the displacement of the upper ulnar fragment. It was now an easy matter to get the ulna into correct position and a good result was thereby ultimately obtained. The case is of great interest when taken into consideration with Professor Macleod's recent paper on this injury, and certainly demonstrates very clearly the great importance of two of his practical precepts—viz.: (1) Whenever we find a fracture of the upper end of the ulna careful examination for a dislocation of the head of the radius should be made; (2) should such a dislocation be found it must be reduced at once and endeavours made to rectify the displacement of the upper ulnar fragment at the same time. From my experience in this case I conclude that the reduction of the dislocation is by far the most important item in the treatment.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

### ST. MARY'S HOSPITAL.

TRAUMATIC PERITONITIS; ABDOMINAL SECTION;  
RECOVERY.

(Under the care of Mr. EDMUND OWEN.)

DURING the last few years there have been many contributions and discussions of moment on the subject of the treatment of peritonitis by abdominal section, and our appreciation of its value in many instances, especially where the inflammation has passed on to suppuration, whether localised or diffused, has grown in proportion to our knowledge. To say that it has proved successful in peritonitis following simple contusion, rupture of viscera by injury, perforation from disease, puerperal infection, tuberculous infection and simple contusion indicates in some way its range of usefulness. We do not urge its employment in every case—far from it; each case must be judged on its

own merits and treated in the way which is most likely to yield the best result. There is no doubt, however, we think, that in the past there has been too great timidity in dealing with the group of cases of which Mr. Owen's is an example—acute peritonitis following contusion of the abdomen. It is true that in this instance the inflammation had been in existence for some time, and therefore there was at first less apparent urgency than in the more acute traumatic inflammations, but it is also evident that without operation only one result—that a fatal one—could have ensued. The reason why peritonitis of such intensity followed the injury in this case will probably not be known; it could not have been due to a rupture of the intestine or of the bladder. In a case of acute peritonitis operated on by Mr. Owen, which was published in *THE LANCET* some years ago, ruptured intestine was found, but the mischief had gone too far for cure and death rapidly ensued. Even in such cases operation may not be too late, for Bouilly has made known a case in which, as a result of operation twenty-eight hours after the kick of a horse which produced a rupture of the intestine, the ensuing peritonitis subsided, after resection and suture, but with the formation of an artificial anus. The proceedings of the French Surgical Congress of October, 1889, a paper by Mikulicz read at the eighteenth German Surgical Congress in 1890, a paper by Krecke in the *Münchener Medizin. Wochenschrift* of 1891, and isolated cases by various surgeons, notably two by Mr. Keetley published in *THE LANCET* (vol. ii. 1888, p. 1021), may be read with advantage. For the notes of the following case we are indebted to Mr. J. W. Summerhayes.

On Friday, June 24th, 1892, a man aged twenty-three was admitted into this hospital with the following history. On the evening of June 7th he was riding a 56 in. bicycle in the country and his lamp went out. This was noticed by a policeman who tried to stop him, with the result that the patient was pitched across the sharp top of a wooden fence. Thus he was struck upon his abdomen, and from the top of the fence he fell to the ground. He was helped up and taken home. Towards the end of the week diarrhoea set in, and on the Sunday his abdomen was swollen and painful. These troubles continued and increased, and on the day before his admission, which, as already noted, was the seventeenth day after the accident, he vomited. He had during this time lost a good deal of flesh. His mother said that he had always been fairly strong, but that one of his brothers had died of "consumption."

When seen in the ward his aspect was much like that of a typhoid fever patient. The pulse was 130 and the temperature was 103°; the face was flushed, but he had no headache; there were no spots. He complained of constant pain, especially on the left side, and the abdomen was considerably enlarged; the peritoneal cavity contained a good deal of fluid, on which the intestines were floating. There was a faint flush of the skin. The bowels were regular. Turpentine fomentations were applied to the abdomen and half-drachm doses of sulphate of soda were prescribed every hour until a free purgation was produced. The diet consisted of a little brandy and beef jelly with some milk. Dr. Sidney Phillips saw the man with Mr. Owen, and on the second day after admission, as the patient was steadily going down-hill and had, moreover, the aspect of one about to die, it was agreed that an abdominal section should be performed, partly with the view of clearing the peritoneum of a possible collection of pus, and partly with the view of searching for and repairing a possibly damaged viscus. As the chief pain lay about the sigmoid flexure the incision, of about three inches, was made in the left linea semilunaris. About five pints of blood-stained serum were removed, together with several large clots of fibrine, which latter, together with a general roughening of the peritoneal lining, testified to the intensity of the serous inflammation. As no intestinal fluids, blood, or actual pus were found, the operation was completed by the closure and dressing of the wound. Next day the pulse had come down to 120 and the temperature to 101°, and on the following day the pulse had fallen to 88, whilst the morning temperature reached only to 99°. The man left the hospital completely recovered at the end of July.

*Remarks by Mr. OWEN.*—If it be urged that abdominal section is a severe measure for adoption in the treatment of traumatic peritonitis, the criticism must be considered fair. But, on the other hand, it would be maintained that the term "peritonitis" includes many various conditions. It was certainly my opinion, as well as that of most of those who watched the case with me, that this operation saved the

man's life. Possibly it was the relief of tension to which the improvement was to be attributed. And if so, a large cannula and trocar might possibly have served as well as a scalpel. But with the use of the former instrument no introspection would have been possible, and an introspection, especially in the case of traumatic peritonitis, may prove of inestimable value. The more that I see of abdominal surgery the more satisfied am I of this—that in an obscure case the only way for the surgeon to assure himself of what is wrong is by the means of transperitoneal touch or sight. To stand at the bedside and take part in a speculation as to what is wrong, and to wait for the necropsy for positive information, is not Surgery. For my own part, I have never yet had cause to regret performing an exploratory abdominal section; but I have often found occasion to mourn for an error on the side of over-caution. There is, I think, a close analogy between a case of inflamed peritoneum and one of acute inflammation of the synovial membrane of the knee-joint. At any rate, the local signs and the effects of tension are alike in each case, and in some cases the indications for treatment are identical. Not a few remember the time when in every instance the surgeon was loth to interfere; but, with the march of science, times are changed; and he is an unwise surgeon who, deeming his therapeutic knowledge to be complete, is disinclined to admit of changes in his routine treatment.

## DENBIGH INFIRMARY.

### SUBCUTANEOUS LACERATION OF THE SMALL INTESTINE; NECROPSY.

(Under the care of Mr. WM. GRIFFITH.)

WE are of opinion that much good will ultimately result from the publication of cases such as the following, in which a fatal peritonitis was found after an injury of the abdomen which had caused rupture of the intestine. There appeared from the history of the case no cause for suspecting the presence of so grave a lesion as rupture of the intestine, for such would, with but few exceptions, be caused by a definite and direct blow. The symptoms were similar to those described in some cases where intestinal rupture has been found post mortem or at the time of operation, but the history was misleading; and it is not surprising that other than operative treatment was tried. Until a few years ago the surgical treatment of subcutaneous rupture of the intestine, even when diagnosed, was based on a policy of "masterly inactivity"; the surgeon watched the case for a time, peritonitis ensued, and it was then too late to do good if an operation was performed. It has been fully proved by Mr. Croft and others that success may follow laparotomy and suture of the bowel, or even the formation of an artificial anus if the operation is done at an early stage, and this must be attempted by the surgeon responsible for the patient. The publication of these cases increases our knowledge of the varying symptoms which may be met with, and more may be gained by the account of them than is apparent always to those under whose care an isolated case may come. We have only to point to the good which has followed the publication of cases of bullet wounds of the intestine by American surgeons, whether the cases ended fatally or not, in order to emphasise this statement. Some of the most brilliant results are now attained after operation for these wounds. Formerly any attempt to save life by means of a surgical operation was considered useless.

R. J.—, a labourer aged twenty-three, was admitted into the Denbighshire Infirmary about 5 P.M. on Aug. 12th, having met with an accident about an hour before while engaged in loading a waggon with timber. His fellow workmen stated that a piece of timber had rolled from the top of the waggon, hitting him on the back and knocking him over. The first shock caused him to faint, but he soon recovered consciousness, complained of pain in the back and abdomen, and vomited. When examined in bed after his admittance he was found to lie on his left side with his legs drawn up, was perfectly conscious and rational, described the accident and gave particulars of his injuries. He had been struck with the timber over the middle and upper portion of the sacrum; there was some swelling and bruising over the spot, but no fracture or dislocation; there was also some bruising over the left hip bone a little below and about two inches behind the anterior superior spine of the ilium and a faint bruise on the front of the abdomen a little below
